Osler's dominant characteristic was undoubtedly his broad humanity. This showed in his teaching; his friendships with high and low, young and old, colleague and pupil; in his speeches and writings; and in his wide and inclusive scholarship. In his last address, made as president of the Classical Association, entitled The Old Humanities and the New Sciences, he made a plea for no human letters without science, and no science without human letters. He once stated that his three ideals for himself were to do well the day's work, to live out the Golden Rule as far as possible, and to cultivate a degree of equanimity that would enable him to bear success with humility, the affection of friends without pride, and to be ready when the day of sorrow and grief came to meet it with the courage befitting a man.

Editorial Articles

MEDICAL PROGRESS IN 1923

Activities along the lines of public health work were perhaps the most notable contributions of the year 1923 to medical science. In their annual summary of progress of the year, the *Nation's Health* calls the passage of the New York act for State aid to local hospital, dispensary, nursing, laboratory and other public health services "one of the really epoch making pieces of legislation in the history of public health. . . . This legislation is not only of unique significance in itself, but it is also memorable as the last great contribution of Dr. Herman Biggs to the cause of sanitary statesmanship." Mention is also made of the creation in the United States Public Health Service of an office of administrative health practice where full data as to the organization and administrative procedure of the health departments of the country will be collected and kept on file for reference. Another step for promoting the progress of city health services was the appointment of Dr. Rankin as director of field service to advise municipal officials as to the development and standardization of their work.

In school hygiene probably the most important contribution of the year was that of Dublin and Gebhard, published in the *Journal of the American Medical Association,* contesting the opinion that malnutrition usually causes underweight children, by showing that clinically undernourished children are in many cases not underweight. In industrial hygiene, probably the most notable contribution was that made by Aub and his associates at Harvard on the pathology of lead poisoning. A study of dust as a contributory cause of tuberculosis was continued intensively at Saranac by Dr. L. U. Gardner and others. Related studies of importance were those made by the New York State Commission on ventilation, published by Dutton, and Vernon's researches in England on the effects of high temperatures and humidities, and also those conducted by the United States Bureau of Mines, the Public Health Service, and the Society of Heating and Ventilating Engineers at Pittsburgh.

Distinct advance has been made in vaccine and serum therapy. The Schick test and the toxin antitoxin immunization have been proved invaluable in the control of diphtheria, and work along these lines has assumed vast proportions. Dr. Park's use of the first injection of toxin antitoxin made subcutaneously instead of the Schick test was a significant contribution to this form of serum therapy. Dreyer's defatted vaccine for tuberculosis and the development of sera for the treatment of pneumoni were other procedures that aroused great interes in the medical profession.

In the realm of etiology advances were not s notable, but Robertson's researches of the effect of atmospheric temperature upon the prevalence o fleas parasitic upon rats and hence upon the inci dence of bubonic plague should be mentioned. Als evidence has been collected and published showin that the streptococcus is probably a causative agen in scarlet fever.

Studies and investigations of the previous yea that have been more fully demonstrated and prove valuable during 1923 are the investigations of Olit sky and Gates on the causative organism of influ enza, and, first and foremost, the discovery of Bant ing and Macleod of the value of insulin in th treatment of diabetes.

BLOOD PRESSURE AND TOXEMIA

High blood pressure, concerning which much i heard nowadays, may be influenced, perhaps largel brought about, by toxemia. Intestinal toxemia, th result of long continued constipation and disordere digestive functions, perverted metabolism, may be th cause, or at least a contributory cause, of hyperten sion and hypotension. That high blood pressure i frequently of toxic origin is the belief of many car diologists. This seems reasonable. According t Alder (*Schweiz. med. Woch.,* 1921, 51, p. 713), unde the influence of infections proteinogenous substance may be formed in the blood, capable of inducin spasm, similar to those which culminate in th eclampsia of pregnancy. Under ordinary circum stances they are dealt with by the liver, but whe the liver suffers as the result of infection, these sub stances accumulate in the blood, and high bloo pressure results from spasm of the arterioles. Th effects of toxemia are most apparent in the kidneys by reason of their vital importance, the manifesta tions produced thus forming only one symptom o the general poisoning. Langdon Brown, in his boo recently published on the *Sympathetic Nervous Sys tem in Disease,* points out that intestinal stasis fron sympathetic inhibition causes poisons of putrefactiv origin to be absorbed, which in their turn lead t vasoconstriction, and hence an unduly raised bloo pressure. Bishop, at the seventeenth Internationa Congress of Medicine, held in London in 1913, ad vanced a conception of a general cellular disorde

om which few cells of the body are exempt. The eart, bloodvessels, liver and kidneys suffer conicuously because of their importance and activity, nd because of the extra strain to which they are put y cellular damage. The rationale is that a reactive ritation is set up against some material with which ie cells have to deal in the processes of cellular utrition, and that this irritation, which is in the ature of an anaphylaxis, leads to cell injury with ltimate destruction and replacement by fibrous tisue. The extraneous material is believed to be a rotein or protein derivative from ordinary food. uch sensitiveness dates usually from some acute lness, from shock or great emotion or from acute ood poisoning. Thus, as Halls Dally has pointed ut in his book on high blood pressure brought out short time ago, although no one factor can be ointed to definitely as the source of origin of abormally high arterial pressure, and it is highly robable that more than one source exists, a mass of vidence has been adduced based on the hypothesis iat the majority of cases of hyperpiesis are in realy due to toxemia arising from infective or autoenetic sources. The results of treatment are rongly in favor of this view.

In the consideration of high blood pressure the ndocrine glands must be borne in mind, but of this art of the subject enough is not known to speak ecisively or dogmatically. Yet enough is known o state that the endocrine glands and the sympaietic nervous system act and react on each other, specially the adrenals, and may have a great deal o do with high blood pressure. It may also be sugested that long continued intestinal toxemia may rejudicially affect the working of one or other or iore of the endocrine glands disturbing their harionious action and interaction essential to good ealth and may be the cause of an unduly high lood pressure.

If alimentary toxemia is a leading factor in the roduction of hyperpiesis, and evidence points that ay, the sensible treatment is to prevent constipaon and the other symptoms of gastrointestinal ouble from reaching the chronic stage. Careful ving and especially diet are perhaps the main preentive measures, plainer living than in these days e are accustomed to. However, therapeutic measres are indicated also. The gastrointestinal tract ust be rid as far as is possible of the material hich is poisoning the system and the functions of igestion and assimilation and peristalsis must be aintained in efficient working order. Also steps ust be taken to free the kidneys from the subances which are clogging their proper action. The nooth working of the urinary apparatus is quite as nportant as that of the gastrointestinal tract. In the checking and amelioration of high blood pressure of toxic origin it is essential that eliminaton and excretion be satisfactory, and elimination by way of the kidneys in particular.

THOSE INSIDIOUS SYNDROMES

Perhaps the most instructive papers which could be read in medical societies would be discussions of mistakes in diagnosis. Until the average psychology of *homo sapiens* has undergone considerable upward revision, however, we fear that such discussion will be infrequent. We do not undertake, with any degree of enthusiasm, the listing of our own errors, and of course our natural courtesy forbids the publishing of those of others. In short, if a physician reads a paper describing mistakes he has made in diagnosis, his colleagues are suspicious of his motives; if he reads a paper describing the mistakes he has seen others make, he is written down as a conceited ass.

But this does not alter the fact that mistakes are being made constantly, and the frank physician will tell you that much of what diagnostic acumen he possesses came from profiting by errors. These mistakes are naturally due to many causes, but possibly the most frequent cause of all is the insidious lure of the syndrome.

A patient is ill with fever. Our best physical examination does not reveal any cause for this, nor any localizing symptoms. Fever and some malaise, that's all. Immediately begins the urge to name it. The physician thinks of malaria or typhoid or typhus or other syndrome, according to the environment. There are several determinants of this anxiety to christen, this what we might call a nosophilia. One is the natural wish of the patient and his relatives to know the name of the illness. Immensely more comforting is the physician who says "O yes, you have a touch of malaria" or "You're threatened with typhoid," than he who frankly says he does not know the diagnosis. And then too there is the comfortable feeling of the physician himself when he thinks of a patient as having this or that definite disorder, as contrasted with the uncertainty of a deferred or unknown diagnosis.

But more potent perhaps is the method of teaching unfortunately too prevalent in medical schools. Let us take neurology for a paradigm. The instructor, after running briefly over some of the more common neurological symptoms, tremors, incoordination, disturbances of reflexes, etc., hastens on to syndromes. In every large centre of population there are available, usually, cases of multiple sclerosis, of syringomyelia, paralysis agitans, tabes, pro-

gressive muscular atrophy, and so on. These make excellent subjects for clinical demonstration. At the end of the school year the instructor has the contented feeling of having given a thorough course in his subject. Hasn't he shown the students some beautiful cases, patients who were veritable neurological museums?

Unfortunately, when the student later hangs up his shingle, these beautiful cases do not troop into his office. When he does get a patient who shows some neurological symptoms, these are likely to be extremely slight and confusing. He puzzles over them and, thinking of the various syndromes described so glibly in his final examination, he finally decides that the patient must have one of them, and proceeds on that theory. And then later he must revise his diagnosis or abandon it altogether.

The aim then of the instructor in the medical college should be, not so much to show classical, textbook pictures of disease, but to prepare the student to recognize departures from the normal, and their individual significance.

ACALCULOUS CHRONIC CHOLECYSTITIS

This affection is of frequent occurrence, but as yet has not been fully explained. It is characterized by a torpid inflammation of the walls of the gallbladder and the clinical symptoms are similar to those of calculous cholecystitis. Acalculous cholecystitis is not so infrequent as might be suspected, because out of a total of one thousand cases, Smithies found the acalculous form in forty-seven per cent., the calculous form in fifty-three per cent., while Henkel and Riedel give a proportion of only ten to twenty-five per cent.

The etiology of this morbid process is not clear. The puerperal state unquestionably exercises a marked action and many gravid cholecystitides are in no way related to biliary lithiasis. Chronic appendicitis frequently accompanies it. In all septic processes the pathogenic bacteria eliminated by the liver enter the bile and irritate the walls of the gallbladder when the bile stagnates in the viscus, hence there is a descending infection of the organ and it now seems probable, from recent researches, that ascending infection is not common, even if it occurs at all.

The inflamed gallbladder often forms adhesions with the surrounding viscera, while in size it may be larger than normal; it is rarely atrophied or contracted. The walls are thickened, the fluid contents are thick, cloudy, and greenish in color, while occasionally a mixture of bile and pus is found.

From the clinical viewpoint the most remarkable fact is the presence of extravesicular symptoms, gallbladder symptoms being very slight or even absent. The former consist of gastric or intestinal disturbances and usually a more or less marked change in the general health. The gastric symptoms consist of gastralgic crises and symptoms of motor hypersensitiveness. In most cases the symptoms of nervous dyspepsia are alone present.

The intestinal disturbances recall those of mucomembranous enteritis; the patient experiences general lassitude, sleeps poorly, loses flesh, and may even present a rise of temperature and chills, often arousing a suspicion of tuberculous infection. In a middleaged subject whose general health is disturbed without any appreciable cause, one should suspect a latent affection of the gallbladder and systematically explore that viscus.

The vesicular symptoms alone will allow the physician to make a diagnosis. These consist of a mild angiocholitis pain in the gallbladder and changes in the duodenal fluid removed by tubage. Angiocholitis is rarely wanting, although greatly attenuated and recalls the tint of familial cholemia. The conjunctivæ may sometimes be slightly tinged. The urine always contains urobilin and the feces are slightly decolorized at the time of the paroxysms.

The gallbladder pain may be found only by pressure over the organ, or the patient may present a true hepatic colic, but usually the patient only complains of a dragging sensation in the infrahepatic region.

Duodenal tubage is of immense value and when done after the subject has been fasting for twelve hours the fluid withdrawn will be golden yellow or brown, thin and transparent and free from any solid particles; it is neutral or alkaline, contains a few cholesterin crystals, some epithelial cells, and numerous bacteria. In cases of chronic acalculous cholecystitis or when calculi are present, the duodenal fluid is thick and viscous, cloudy, yellowish green, containing numerous polynuclears, and other figured elements.

The evolution of acalculous chronic cholecystitis is extremely slow. There are mild forms and serious forms with rapid emaciation and loss of strength. Occasionally there is suppuration of the gallbladder with all its consequences. The acalculous type may end in calculous cholecystitis and this is not uncommon. Naunyn, Mignot and Gilbert have demonstrated the infectious origin of biliary lithiasis, while Chauffard and his coworkers have demonstrated the formation of cholesterin calculi resulting from hypercholesterinemia from stasis. Also the researches of Moynihan, MacCarty and Gosset have shown that great attention should be given to a

traparietal origin of calculi. An infiltration of holesterin may occur under the intact vesicular pithelium within the cells of the mucous chorion. his lithogenous process is all the more likely to ccur the greater the chronic inflammation of the allbladder.

The differential diagnosis between acalculous ronic cholecystitis and chronic appendicitis must e made. The former process occurs mostly in omen between twenty and fifty years of age. adiography and duodenal tubage will confirm the resence or absence of calculi. When they are absent ie radiograph will be negative and duodenal tubage ill withdraw a normal fluid, and lastly, there is no ypercholesterinemia of the blood.

In the acalculous type of chronic cholecystitis, rotropin, oil of juniper and vichy water are the ost effective remedies and often result in an evident amelioration, but this medication must be continued for months or even years. If after a ufficiently prolonged medical treatment, no improvement is forthcoming, cholecystectomy will give satisfactory and lasting results.

THE EFFECTS OF ALCOHOL

In these days of pros and antis in regard to prohibition, it is refreshing and most helpful in judging he problem to find a scientific and authoritative eries of opinions on the subject. Such a series may e found in the volume, *The Action of Alcohol on Man*, by Ernest H. Starling, late professor of physiology at University College, London, with appended ssays on the subject by the well known authorities, Dr. Robert Hutchison, physician to London Hospital, who writes on Alcohol as a Medicine; Sir Frederick W. Mott, pathologist to the London County Council Asylums, whose subject is Alcohol nd its Relations to Problems in Mental Disorders; nd Raymond Pearl, Ph.D., of Johns Hopkins, who liscusses Alcohol and Mortality. The book is a recent publication of Longmans, Green & Company.

Starling, who writes the preface to the volume, states that his conception was that such a book, written from the purely scientific viewpoint, would make it possible to find material on which to base arguments for or against the use of alcohol. He himself is convinced that in a civilized society such as ours the abolition of all alcoholic beverages, even with universal consent, would be "a mistake and contrary to the permanent interest of the race. If it were enforced by legislation," he writes, "against the wishes and convictions of a large proportion of the members of the community, I believe it would be little short of a calamity. While it would not result in the long run in the improvement of national health and efficiency, it would diminish that respect for the law and that identification of self with the law which are essential for the stability and welfare of a democracy." Through more than half of the volume, Doctor Starling develops the reasons why he has arrived at the above conclusions. He believes that the whole question as to the effects of alcohol depends upon the distinction between use and abuse. "In moderation it is difficult to appreciate any harmful effects from its use, whereas, when temperance is abandoned and alcohol is used immoderately, its effects are evil and fraught with disaster to the individual and damage to the community." To sum up the conclusions at which he has arrived through his studies and investigations, he finds alcohol in many cases a valuable food, as, for instance, for diabetics, and for the old. As a drug, alcohol is always from beginning to end a depressant, not a stimulant. The narcotic action is sometimes of value in relaxing tension of the highest brain centres, in promoting repose and freedom from care and worry, in assisting digestion and assimilation, and as a restorative under certain conditions. On the other hand, alcohol is always injurious in its effects when taken immoderately or over a long period of time. Also, for the psychopath, for the man who has a weak nervous inheritance or who has suffered a head injury, *any* use of alcohol is immoderate, and the same applies to children and young people during growth, while the processes of control are being perfected by education and discipline.

Sir Frederick Mott's article gives some very interesting data and statistics on the relation of alcohol to mental disorders. He quotes Doctor Sullivan's conclusions regarding alcoholic influence in the production of certain evil social phenomena in England. Probably chronic alcoholism is the cause of a considerable proportion of the suicide of that country, and an important factor in the large increase in suicides during the last few decades. He concludes that chronic intoxication is responsible for about three fifths of the homicidal crime in England, and that, in rather less than half the cases of sexual crime, the causal condition is either chronic alcoholism or simple drunkenness. In crimes of acquisitiveness, alcoholism seems practically a negligible quantity. His general conclusions do not differ appreciably from those of Starling. Dr. Raymond Pearl finds that the consumption of alcoholic beverages in moderate quantity does not sensibly shorten the mean duration of life nor increase the rate of mortality as compared with that of total abstainers; but that the excessive use diminishes the mean duration of life and increases the mortality rate.

THE VALUE OF HEALTHY TEETH

Through the realization of the effect of dental conditions on health, and that the science of dentistry is not only palliative and curative, but definitely preventive, the Government of Great Britain has started the organization of a State and local dental service, to work in cooperation with the many clinics established by large industrial firms, and with a panel dental service that has already been established in various parts of the country.

A departmental committee was appointed not long ago to study and review dental conditions in the kingdom, and much interest has been aroused by their report, which states that at least one third of the general diseases of the people as a whole are due, directly or indirectly, to bad teeth and their consequences. An experiment was tried out at a school dental clinic at Cambridge. It was found that in 1908 only fifteen per cent. of the children had sound permanent teeth. In 1920, as the result of preventive care and treatment, these figures showed themselves as directly reversed—fifty-one per cent. of the children had sound permanent teeth, to say nothing of numerous other benefits accruing to their possessors, such as the avoidance of gastrointestinal disorders, glandular infection, anemia, and toxic states of all kinds.

At the last annual meeting of the British Dental Association, the president, Dr. George G. Campion, made a plea for the realization on the part of the dental profession of the fact that the place of dentistry in this new era of medical science is distinctly that of prevention rather than of treatment and cure.

OCCUPATION AND GENERAL PARALYSIS

Although occupation is not a primary cause of general paralysis, a study of its incidence in a group of workers is important as bearing upon its prevention, by showing what occupations may hasten its development in persons already infected with syphilis. Dr. Horatio M. Pollock and Dr. William J. Nolan have presented, in a recent issue of the *New York State Hospital Quarterly,* an interesting study of this subject.

This study included both males and females from all industries, who had been admitted to New York civil State hospitals during a certain period of time. In the female group, 71.5 per cent. of the patients had been employed in domestic and personal service. With due allowance for difficulties in classification, some very interesting estimates as to incidence were able to be made. The occupations having the lowest rate of general paralysis were, in the order given, mail carriers, laborers, porters, etc.; street car conductors, and persons in the printing and publishing industries. Among persons in occupations having a high rate were, in the order given, first, actors, with a percentage of 1,207.1 to 100,000; second, bartenders, with a percentage of 914.2; third, waiters, with a percentage of 767.4. The lowest in this group were the captains, masters and pilots, with a percentage of 304.71 to 100,000.

In recent years, the report states ,about twenty per cent. of the males and about five per cent. of the females who were first admitted to civil State hospitals have been cases of general paralysis. The deaths from general paralysis in these hospitals have been approximately twenty per cent. of the total number of deaths in the institutions.

Obituary.

SIR MALCOLM MORRIS, M.R.C.S., F.R.C.S., EDIN.

Sir Malcolm Alexander Morris, the well known dermatologist, died suddenly at Bordighera on February 19th, aged seventy-four years. He was born in London, the fifteenth child and youngest son of Mr John Camac Morris, F.R.S., of the Madras Civil Service. He received his medical education at St Mary's Hospital, and after he had qualified as M.R.C.S., he engaged in medical practice for a year but not liking the work went to Berlin and Vienna where he became especially interested in the diagnosis and treatment of diseases of the skin. Returning to England he was appointed clinical assistant to the Blackfriars Hospital for Diseases of the Skin and in 1879 published a *Manual of Skin Diseases* which ran through several editions. In that year too, he began to lecture on dermatology at St. Mary's Hospital and in 1882, having been admitted F.R.C.S. Edin., became surgeon in charge of the skin department of the hospital, a position he held for twenty years. He did much to raise the standard of the medical school of St. Mary's Hospital.

Early in his career Morris was particularly concerned with the treatment of lupus. Koch's discovery of the microorganism causing tuberculosis quickly attracted his attention, and he was foremost among those in England who appreciated its importance. He represented the National Association for the Prevention of Tuberculosis at the Congress which was held in Berlin in May 1899, and in 1901 he was secretary-general of the British Congress on Tuberculosis, at which Koch endeavored to show that essential differences existed between human and bovine tuberculosis. In 1901 he delivered the Lane Lectures in San Francisco.

He lectured for several years on dermatology at the London School of Clinical Medicine, and he was surgeon to the skin department at the Seamen's Hospital, Greenwich. He was honorary or corresponding member of the French, Italian and American Societies for the study of dermatology, a past president of the Dermatological Section of the Royal Society of Medicine, and a member of the International Council on Leprosy. Morris had a strong leaning to literature and was a facile speaker and writer. He possessed extraordinary energy and a peculiarly alert brain. In 1883, Messrs. Cassell and Co. published under his editorship *The Book of Health.* This was followed by two series of excellent manuals, the one dealing with physiology, pathology and comparative anatomy, the other with clinical subjects. In 1886 he was coeditor with Dr. M. Hays, of Philadelphia, Pa., of the *International Journal of the Medical Sciences* and from 1895 to 1902 he edited the *Practitioner.* In 1921, he edited, in association with Professor Langmead and Dr. Holmes, a three volume *Dictionary of Practical Medicine.*

News Items

Conference on Infant Welfare.—The third English peaking conference on infant welfare will be held in London on July 1st, 2nd and 3rd.

American College of Physicians.—At the annual meeting of the American College of Physicians, held in St. ouis, Mo., February 18th to 23rd, Dr. Harlow Brooks, of ew York, was elected president.

Memorial Meeting for Dr. Holt.—A special meeting as held at the New York Academy of Medicine, Wednesay, March 12th, in commemoration of the life and services f Dr. L. Emmett Holt.

Poughkeepsie Officials Want Hospital for Contagious iseases.—A movement is on foot in Poughkeepsie, . Y., to secure a city hospital for the treatment of conagious diseases. There is no place for the isolation and are of such cases in that city at the present time.

Dr. Park Elected to French Academy.—Dr. William . Park, professor of bacteriology and hygiene at the niversity and Bellevue Medical College, has been elected foreign member of the Paris Academy of Medicine.

International Society of Medical Hydrology.—A spe-al meeting of the society was held at the Royal Society f Medicine, London, on Wednesday, March 5, 1924. A iscussion on the treatment of tropical disease by waters nd baths was opened by Dr. Pierret, of La Bourboule, rance.

Free Dental Clinic for the Bronx.—The Northern istrict Dental Society of the Bronx is planning to erect s own free dental clinic, to cost $100,000. This is to replace ie present clinic, where 15,000 school children were treated st year. A rally to further plans is to be held at the oncourse Plaza Hotel on March 28th.

Gift to Northwestern University Medical School.—Irs. Robert L. Rea, of Chicago, widow of Dr. Robert aughlin Rea, for thirty years surgeon in chief of the ennsylvania Railroad, has given to Northwestern Univerty Medical School, Chicago, $100,000 with which to estabsh a permanent professorship in anatomy.

Schools to Retain Dental Clinics.—The Board of Eduation has rescinded its action abolishing dental clinics in ie city's public schools. Dr. John A. Ferguson, physician the Mayor, who made the original motion to abolish the inics, introduced the resolution yesterday to continue exting clinics as formerly, but to provide no new ones.

Friday Afternoon Lectures at the Post-Graduate.—he following Friday afternoon lectures will be given at o'clock at the New York Post-Graduate Medical School nd Hospital during the month of April: April 4th, Röntgen Therapy, by Dr. William H. Meyer; April 11th, adium in Diseases of the Skin, by Dr. A. Schuyler Clark; pril 25th, The Diagnostic Significance of Abdominal Pain, y Dr. Ludwig Kast.

Public Health Service to Conduct Summer Schools i Public Health.—The United States Public Health ervice has made arrangements with a number of universies throughout the country whereby summer schools in ublic health will be held over a period of six to eight eeks during the coming summer. In New York State ie course will be given at Columbia University, July 7th August 15th. For particulars address the United States ublic Health Service, Washington, D. C.

Doctors Quit Bay Shore Hospital.—Because of a difference of opinion in regard to the administration of the ospital, twenty-eight doctors, or sixty per cent. of the edical staff, of the South Side Hospital have tendered ieir resignations. It is understood that the action on the art of the physicians marks the culmination of a disagreeent that has existed for some time between the Board of anagers of the hospital and the members of the medical aff. The medical board is headed by Dr. William H. oss and Dr. James S. Ames of Babylon is secretary.

Diphtheria Immunization in Parochial Schools.—chick testing and diphtheria immunization work are being arried out on an extensive scale in the parochial schools f Syracuse and Auburn, N. Y., where beneficial effects re already apparent. Consent was received from 1,928 arents of children in Syracuse, and in Auburn 1,334 Schick ests were made. During the month of January as a result f previous immunization work carried on in that city, nly three cases of diphtheria were reported, namely, two dults and one child; none of whom had been immunized.

Smallpox in Chicago.—Ten new cases of smallpox were discovered in Chicago on March 3rd, which brought the total number of cases up to twenty-five within a week. St. Elizabeth's Hospital in North Claremont Avenue has been quarantined as a result of finding a smallpox patient in the hospital and eleven nurses who were not vaccinated.

Rockefeller Foundation Gives $400,000 to Washington University Medical School.—The General Education Board of the Rockefeller Foundation has donated $400,000 to Washington University, St. Louis, Mo., for the endowment of a department of bacteriology and preventive medicine in the medical school of the institution.

Sewage Menace to Water Supply Must Be Abated.—As a result of a formal hearing held by the State Commissioner of Health on February 14th, the village of Hastings has been granted sixty days in which to abate the nuisance created by inadequate sewage disposal which for many years has affected not only the village of Hastings, but indirectly constituted a menace to the drinking water supply of the city of Yonkers.

The Lane Lectures.—Dr. Ludwig Aschoff, professor of pathology at the University of Freiburg, Germany, will deliver the five Lane lectures for the year 1924. These lectures will be given in Lane Hall, Stanford University Medical School, San Francisco, some time in May. The topics of the lectures are: The Place of Origin of Biliary Pigment; Atherosclerosis; Ovulation and Menstruation; Inflammation, and Fatty Changes in Disease.

Dr. Cumming Retains Post of Surgeon General.—Dr. Hugh S. Cumming was confirmed on March 1st as surgeon general of the Public Health Service. It was said that the confirmation was unanimous. Dr. Cumming, who has been in the Public Health Service since 1894, was nominated surgeon general by former President Wilson in January, 1920, and continued in that post through the Harding administration.

Association of American Medical Colleges.—Dr. Ray Lyman Wilbur, of Stanford University, was elected president of the Association of American Medical Colleges, at the fourth annual meeting of the association, held in Omaha February 28th to March 1st. Other officers were elected as follows: Dr. Hugh Cabot of the University of Michigan, vice-president; Dr. F. C. Zapffe, of Chicago, secretary; Dr. David L. Edsall, of Harvard University, chairman of the executive council. The next annual meeting will be held in Boston in February, 1925.

Country Home for Drug Addicts Who Undertake Voluntary Cure.—Dr. Carleton Simon, Deputy Police Commissioner in charge of the narcotic division, New York, announces that an anonymous friend has placed at his disposal a country estate on the banks of the Hudson for the drug addicts who undertake the voluntary cure provided by the state. They can go to this home in the country and stay for an indefinite period free of all expense, with a guarantee that their identity will never be revealed. Twenty-five drug addicts are taking advantage of Dr. Simon's free cure. All are men from eighteen to thirty-five years of age.

Personal.—Dr. Edward Salmon, a medical inspector in the Jersey City Health Department, has been appointed acting health officer to fill the vacancy caused by the death of Dr. Joseph Craven.

Dr. Herman B. Allyn has been appointed chairman of the section in general medicine of the College of Physicians of Philadelphia, and Dr. E. J. G. Beardsley, clerk. The executive committee consists of Dr. David Riesman, Dr. O. H. P. Pepper, and Dr. John H. Musser, Jr.

Dr. Donald B. Armstrong has resigned as executive officer of the National Health Council and has accepted an appointment as assistant secretary of the Metropolitan Life Insurance Company.

Lectures on Tuberculosis and Industrial Hygiene for Physicians.—A six weeks' combined course on tuberculosis and industrial hygiene for medical practitioners has been arranged at the New York Academy of Medicine under the joint auspices of the Public Health Committee of the Academy, the New York Tuberculosis Association, and the Division of Industrial Hygiene of the New York State Department of Labor.

The lectures will be held at the Academy on Tuesday and Friday afternoons at 4:30, beginning March 14th and ending April 22nd. Two lectures of thirty minutes each, one on tuberculosis and the other on some phase of industrial hygiene, will be given at each session. An additional half hour will be devoted to answering questions from the floor.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

LONDON, *February 1, 1924.*

DR. W. SEAMAN BAINBRIDGE'S REPORT ON THE RUHR AND RHINELAND CONDITIONS

A report on the conditions in the Ruhr and Rhineland during the summer of 1923 made to the Council, New York Commandery Military Order of Foreign Wars of the United States, by Dr. William Seaman Bainbridge, was largely copied and editorially commented on by a London daily recently. While it does not come within the scope of a medical journal to deal with matters political, it may be said that in this country owing, of course, largely to the publicity given to the report and the editorial comments thereon in the daily press, it has attracted a great deal of attention.

INFLUENZA IN GREAT BRITAIN

Influenza is now widely distributed over the country, but generally speaking the type is mild. It seems to be a form of the affection in accord with the 1923 epidemic of grippe, described by Dr. B. M. Randolph in the January 16th issue of the JOURNAL. Both bronchial and gastrointestinal forms are frequent, and the nervous system is subject to a considerable amount of disturbance. As usual insomnia and depression are marked features. Of course, the complications and aftereffects of this insidious disease are most to be dreaded. So far, streptococcal complications have been few and far between and consequently the mortality has been low.

THE MONKEY GLAND TREATMENT

The socalled monkey gland treatment was made the subject of a lecture by Professor Winifred Cullis at King's College, London, on January 5th, last. Professor Cullis explained all that is known of the ductless glands and said that the study of these glands was one of the romances of the past twenty or thirty years. She pointed out that women were more prone to disturbances of the thyroid gland than were men, and remarked in this connection that all the women in the paintings of Burne-Jones and Rossetti showed distinctly enlarged glands. The thyroid gland was the controller of the rate of living and in man it was larger in proportion than in other animals. It had been suggested that it was owing to the presence of the thyroid that a sea animal changed to a land animal; and some support was lent to this theory by the fact that only when thyroid secretion was present could a tadpole change to a frog. Were thyroid added to the water in which the tadpole was living the process of the change would be hastened, and the frog would be rapidly formed, though of very small size. A gland which was of vital importance was the pituitary, upon which depended our growth. The lecturer told of an undersized schoolboy who, upon being given treatment for a deficiency of the gland, grew two and a half inches in one term. In view of this very rapid growth the treatment was discontinued, and at once the boy stopped growing. Professor Cullis humorously alluded to the incident in *Alice in Wonderland* where Alice ate from one side of the mushroom and instantly grew, and she added tha the fat boy in *Pickwick* was clearly suffering fron a complaint of the pituitary gland. At the conclu sion of her lecture Professor Cullis referred to th socalled monkey gland treatment. It was absurd she said, to speak of monkey gland as if the monke had only one gland. Having indicated the partic lar secretion which was used in the treatment th lecturer pointed out that Voronoff maintained tha senility was due to the failure of the internal secre tions. She was present at Edinburgh when he lec tured and by means of a cinematograph film h demonstrated his treatment, which according to th films was strikingly, almost absurdly, successful i imparting energy and vitality to the animal or ma upon whom the treatment was employed. Professo Cullis, however, uttered a note of warning again expecting too great results from the method. Sh concluded that if these changes could be produce it must not be supposed that the treatment meant a increase of longevity. It did not. What it mea was that the human powers would be utilized rig up to the last. If what we desired was to increa the span of life we would have to turn to eugenic

TOLL OF LONDON TRAFFIC

Street accidents in London during the months o October, November and December last numbered fewer than 18,592, and in that period 189 perso were killed. Omnibuses were responsible for thirt six deaths; private motor cars for forty-seven; tra and commercial motors of one kind or another f sixty-one; motorcycles, nine; taxicabs, fourteen; ar tramcars, three. Fatal accidents in which hor drawn vehicles were concerned numbered fourte

GIFTS TO MEDICAL SCHOOL OF CAMBRIDGE UNIVERSI

It is announced the Rockefeller Institute h most generously made an offer of £100,000 for t construction and maintenance of a new School Pathology at Cambridge University, together with contribution of £33,000 towards its endowment, pr vided that the university can secure a furth £33,000 for the same purpose. Mr. and Mrs. P. Molteno, to whose munificence the university already owes the Institute of Parasitology whi bears their name, have further endowed it with sum of £5,000 to meet certain deficits, and to incre the endowment fund.

HEALTH SECTION OF LEAGUE OF NATIONS

Owing to the generosity of the Rockefeller Fu Trustees, the League of Nations which has alrea done much in fighting disease in Eastern Europe, about to inaugurate a scheme calculated to be great service to international health. A sum money is now available to enable medical officers health to visit foreign countries and take perso part in the work of prevention and administrati The Ministry of Health has given full support to scheme. It is an interchange of medical offic which should promote good feeling as well as go health.

FATAL ACCIDENT TO A WELL KNOWN ANESTHET

Dr. George A. H. Barton, the well known an thetist, when riding in Hyde Park on January 1 last, was thrown from his horse and died in George's Hospital as a result of the injuries receiv

LATIN AMERICA LETTER

(From our own correspondent)

BALBOA HEIGHTS, C. Z., *January 30, 1924.*

TO INVESTIGATE THE BLONDE INDIANS OF PANAMA

Mr. R. O. Marsh, of New York, who lays claim to having discovered a race of white Indians in the lower part of the Chucunaque Valley, recently arrived on the Isthmus at the head of an expedition of anthropologists, archeologists, geologists, zoologists and biologists from the Smithsonian Institute and Museum of Natural History of Washington, D. C., the George Washington University, the American Museum of Natural History, the University of Rochester and the New York Zoological Society. Among those in his party are Dr. Herman L. Fairchild, of Rochester, N. Y., Professor J. Baer, Dr. C. M. Breder, Jr., and Mr. Paul Benton. Other scientists are expected to arrive in the near future and the expedition which will include fifteen prominent investigators will then trek for the hinterland.

The primary purpose of these workers will be to make a complete ethnological, archeological and anthropological survey and exploration of the entire Darien district including the San Blas region. This territory lies in the eastern part of the Republic of Panama not far from its junction with the Republic of Colombia. The expedition will start down the Pacific Coast, through San Miguel Bay and up the Tuira River to the native town of Yavisa near the mouth of the Chucunaque River where the headquarters of the explorers will be located. Thence they will proceed up the river in shallow draft boats with outboard motors. Later they will cross over the divide to the Bayano River and descend to the River Chico. Another party will go up the Tuira River to Santa Cruz de Cana and cross to Piñas Bay. A third party will cover the entire San Blas coast from the Gulf of San Blas eastward to the Colombian border. The scientific equipment of the expedition includes all requisites for making taxidermic and ornithological collections, a complete motion picture outfit and instruments for various types of surveys. There are many physicians here who would make almost any sacrifice to accompany Mr. Marsh but most of them are wholly sceptical of his claims to a discovery of true white primitives among the native tribes. It is his belief that the seven white Indians which he saw and photographed in his most recent expedition came from the mountain hinterlands, a region which it is hoped to visit and study thoroughly.

This should be an undertaking of great interest since even the Conquistadores were never able to penetrate that area. Mr. Marsh refutes the common belief that the Indians which he saw are albinos, maintaining that they are a remnant of a prehistoric Nordic infusion or perhaps the remnants of a very ancient primitive paleolithic race analogous to the Cro-Magnon man of Western Europe. Many of us here have made voyages into the San Blas country and have seen the albinos who are there. Some of them are quite devoid of pigment but many have red hair and blue eyes with very fair skins. These are not believed to be the result of miscegenation since the San Blasians are scrupulous to the point of rudeness that no representative of any other race shall spend the night on their islands. Their women are guarded in a manner which would make a Turk envious and there has been no infusion of outside bloods. Infidelity on the part of their women invariably results in immediate divorce by the route of sudden death, thus definitely assuring that no immoral Nordic has left behind him a blonde heritage. Albinos, however, are not at all uncommon. Just why they are no one seems to know, and it may be that they are related in some way to the whites which Mr. Marsh saw. While the medical men here are preserving a healthy scepticism on the subject, the romance and the lure of this exploring expedition intrigues them greatly and they await the outcome with great interest.

NAVAL MEDICAL OFFICERS DETACHED FROM SUBMARINE BASE

The following officers of the Medical Corps of the Navy who have been attached to the Submarine Base at Coco Solo during the recent maneuvres have been ordered to ships:

Lieutenant Commander R. F. Jones, M. C., U. S. N. to the *Savannah.*

Lieutenant Commander R. H. Miller, M. C., U. S. N. to Destroyer Division No. 27.

Lieutenant G. H. Mankin, M. C., U. S. N., to the *Camden.*

They have been relieved by the following officers:

Lieutenant H. S. Cragin, M. C., U. S. N., from the *Camden.*

Lieutenant J. E. Henry, M. C., U. S. N., from the *Maryland.*

Lieutenant M. S. Stover, M. C., U. S. N., from Destroyer Division No. 27.

NEW CHIEF QUARANTINE OFFICER

Surgeon C. P. Knight, United States Public Health Service, is expected to arrive on the Isthmus on February 13, 1924, for the purpose of relieving Surgeon W. C. Rucker, United States Public Health Service, who has been Chief Quarantine Officer since October 28, 1920. He will take up his new duties about March 6th when Dr. Rucker will leave for the United States. During the past three years many advances have been made by the Quarantine Division, including the introduction of wireless pratique, the adoption of a new type of quarantine declaration, the improvement of the technic of ship fumigation and the abolition of unnecessary and time consuming delays to ships. At the present time ship and passenger delays and detentions have been reduced to the minimum compatible with safety to the health of the Canal Zone and the Republic of Panama. Large advances have been made in the cooperative efforts with other countries to prevent the spread of communicable disease and these have culminated in the Conference of the Maritime Quarantine Authorities of the West Coast of South America which the Republic of Panama is convening on February 25th. This conference is the conception of Dr. Rucker who in organizing it and carrying it to completion makes it the fitting climax of three years of constant labor, having for its object the rationalization and modernization of maritime quarantine on the Isthmus of Panama.

SAFE MILK FOR PANAMA

Dr. Henry Goldthwaite, health officer of the city of Panama, issued an order that, beginning with January 25th, the sale of milk which has not been pasteurized or is not contained in bottles of approved sanitary pattern may not be sold. The Alcalde of the city issued a proclamation requesting the ready compliance with the order by all milk dealers. The proclamation was widely distributed and the city placarded with brilliant red notices calling upon the population to insist on pasteurized milk for the protection of the health of children and the prevention of the spread of tuberculosis, diphtheria, typhoid fever, scarlet fever and dysentery.

INCREASE IN PAY FOR NURSING PERSONNEL

Effective January 1, 1924, Colonel J. J. Morrow, the Governor of the Panama Canal, has authorized a ten dollar monthly pay increase for all nursing personnel.

REDUCTION IN CHARGES FOR FUMIGATION OF VESSELS

The Governor of the Panama Canal announced on December 4, 1923, the reduction of charges for the fumigation of vessels to actual cost plus ten per cent. This was done to stimulate the fumigation of vessels at Canal Zone ports in order better to protect the health of the Isthmus and to control further the world spread of bubonic plague through the medium of ship borne rats. It is believed that this cost reduction, in addition to the improved methods of fumigation which are employed, will make ship fumigation at Canal Zone ports attractive to shipping owners. Cyanogen chloride is now used exclusively as a ship fumigant. Talc is not employed in its liberation and the work has been so systematized and perfected that the gas is gotten into and out of the ships with the utmost rapidity, thus guaranteeing to ships the minimum of time losses.

The announcement mentioned above also abolished charges for quarantine inspection of vessels arriving after 6 p. m. and before 10 p. m. This will be an accommodation to ships and the Canal alike since if a vessel is inspected the night before it will be ready to begin its transit of the Canal early the next morning. This is in line with the policy of rendering to ships quarantine service with the minimum interference with commerce. Speed launches are used by boarding officers and every other measure which will conserve time has been put in force. As a result the number of ship days lost on account of quarantine has been reduced from 480 in the fiscal year 1920 to zero ship days in 1923. This has been accomplished without increasing the health hazard to the Canal Zone and the Republic of Panama. It is estimated that the average value of a ship day is about $2,800, hence losses to shipping have been reduced by about $1,000,000 since 1920.

As an extension of this policy, vessels arriving after 10 p. m. and desiring to bunker are taken to a fuel dock in quarantine under the guarantee that no person or thing shall leave the ship until *pratique* has been granted. During the night the vessel bunkers and at a suitable hour the next morning receives quarantine inspection, after which, if *pratique* is granted, it is ready to proceed. This has proved of great benefit to ships and passengers alike and is entirely logical because a properly ratguarded vessel at dock in quarantine is no more dangerou to the health of the Canal Zone than one which i idly swinging around her anchor out in the bay an the time thus spent had much better be employed i taking on fuel for the continuation of the voyage.

NEW FORM OF QUARANTINE DECLARATION

On December 15, 1923, the Governor of th Panama Canal instituted a new form of quarantin declaration to be sworn to before the Quarantin Boarding Officer by the master and the surgeon o the vessel. Quarantine officers have the legal author ity to administer oaths and for this purpose hav the powers of notary public. A false oath unde these circumstances constitutes perjury. The ne quarantine declaration is very specific and if th quarantine officer is satisfied that the statement i true, that the vessel comes from a clean port and ha a good sanitary history, he is authorized to acce the declaration in lieu of quarantine inspectio Those persons destined to places in the Canal Zon are given the immigration inspection by him but th other passengers and the crew are not examine This facilitates enormously the movement of shi through quarantine and spares passengers muc inconvenience.

INTERNATIONAL COOPERATION IN MARITIME QUARAN TINE

In his annual report for the fiscal year 1923, th Governor of the Panama Canal says: "Throughou the year the policy of extending cooperation wi other nations in the matter of quarantine has be continued. The chief quarantine officer visited th principal ports of Central America on both the Paci and the Caribbean coasts and the west coast of Sou America as far south as Valparaiso. As a result, better mutual understanding was created and th interchange of sanitary reports increased.

"The chief danger which threatens the Panam Canal in the matter of maritime quarantine is th presence of bubonic plague in west coast Sou American ports. If this disease should gain ent into the Canal Zone, it is not probable that the would be any great epidemic, but there probab would be a certain amount of falling off in the nu ber of ships transiting the canal, since undoubted the presence of plague at this point would resu in the imposition of quarantine by other governmen The work of making the Canal Zone proof agai the introduction of plague, by the elimination of r harboring places and catching of rats, was ene getically continued during the year.

"Yellow fever has ceased to be a menace. Duri the year an epidemic outbreak occurred in the i terior of Colombia, but aside from the small restr tions which this necessitated, quarantine was n imposed against any country on account of yell fever.

"The policy of moving the ships through quara tine with the utmost expedition has been continu During the year no ship has been detained in qu antine. This has reduced very materially the los which ships formerly suffered in this way. F example, in 1920 the estimated loss on account quarantine delays was $10.75 a thousand tons shipping. In this fiscal year the estimated loss w $0.027 per thousand tons of shipping."

GENEVA LETTER

(From our own correspndent)

GENEVA, *November 1, 1923.*

SYPHILIS AND TUBERCULOSIS.

The coexistence of syphilis and tuberculosis has been found to be four per cent. in the cases studied by Dr. G. Roque, of Lyons. Unquestionably, it is of the utmost importance to treat syphilis when combined with tuberculosis, but the exhibition of potassium iodide is dangerous and should be proscribed. Mercurial treatment is very slow in action and must be continued for a long time, and on this account it produces anemia and emaciation. Mercurial preparations may remain without effect, even after prolonged administration, which is not devoid of danger, and in all cases where Dr. Roque noted good results mercury had been associated with arsenobenzol. Hence, he believes that arsenical treatment is the really efficacious one, but it is dangerous, because the liver in tuberculous subjects is invariably diseased, and in some patients a superadded arsenical toxemia is quite enough to create an hepatic insufficiency resulting in an acute outburst in the development of tuberculosis.

Roque, however, is not inclined to reject arsenobenzol treatment, because its action is certain and great amelioration, or even cure, may result from its use, but treatment should never be begun before a series of laboratory tests has been made demonstrating the functional activity of the hepatic cells. Should these tests reveal hepatic insufficiency, arsenical treatment must never be resorted to as it courts disaster; instead of checking the evolution of the tuberculosis associated with the syphilis it hastens its development.

In speaking of syphilis, it may be interesting to refer to some recent work done at the Psychiatric Clinic of Lille, France, by Nayrac and Demacou, with Targowla's precipitation reaction in the cerebrospinal fluid with tincture of paregoric. In syphilis of the neuraxis a more or less marked precipitation is supposed to occur in an emulsion of the cerebrospinal fluid and the paregoric. The results obtained by Nayrac and Demacou in forty cases are as follows:

In the first place, in twenty of these subjects with syphilitic lesions of the central nervous system, the paregoric reaction was in accord with both the clinical findings and the Bordet-Wassermann reaction. These cases consisted of general paralysis, tabes, taboparalysis and cerebral syphilis. In seventeen subjects both the clinical findings and the Bordet-Wassermann reaction negatived syphilis. These cases comprised chronic delirium, circular psychoses, epilepsy, senile dementia, mental confusion, dementia precox and arrested mental development. In all of them the paregoric reaction was negative. In three other cases the paregoric reaction was in contradiction with the Bordet-Wassermann. In two of these cases—clinically taboparalysis and general paralysis respectively—Targowla's reaction was distinctly positive, the Bordet-Wassermann being negative. In the third case—a periodical psychosis—Bordet-Wassermann was negative, while the paregoric reaction was weakly positive.

In other words, in thirty-nine cases out of forty, that is, 97.5 per cent., the paregoric reaction was in accord with the clinical findings. In thirty-seven cases out of forty, that is, 92.5 per cent., the Targowla was confirmed by the Bordet-Wassermann. If one only takes into consideration mediumly or strongly positive paregoric reactions, it can be said, as Nayrac and Demacou maintain, that the paregoric reaction is a positive proof of nervous syphilis.

LABORATORY DIAGNOSIS OF TYPHOID INFECTIONS.

In the laboratory diagnosis of typhoid infections, hemoculture or Widal's serodiagnosis will always lead, but the former test cannot always be carried out by the busy practitioners in every case, while Widal's seroreaction, although easier to undertake, its tardy appearance—at about the eighth day of the disease—and its default when the patient has become vaccinated, thus confering on the blood the power of agglutination, may result in difficulties in practice. Because of these reasons, Dr. Henri Bonnin, physician to the Bordeaux Hospitals, has experimented with a number of the more recent diagnostic reactions of typhoid infections and has come to the conclusion that the only really scientific ones are Ehrlich's diazoreaction and the reaction of Moriz Weisz. Each of them is founded on the same principle, namely, the search for a product of disassimilation of the endogenous albuminoids—urochromogen. The Moriz Weisz reaction is more delicate than Ehrlich's and is often positive when the latter is not. Likewise it appears earlier and lasts longer than the diazoreaction. Given these data, it can be said that they both are early and faithful diagnostic aids in typhoid; the Weisz reaction, in particular, appears on the third or fourth day of the disease, therefore, before the seroagglutination. Both these reactions go apace with the evolution of the malady and also indicate with exactitude the approach of a relapse.

Their importance from the viewpoint of prognosis, especially Weisz's reaction, assumes great value in pulmonary tuberculosis; when positive, and sometimes followed by the diazoreaction, it indicates death within a few months. Both these tests are irregularly positive in a large number of diseases, Weisz's in particular, such as the eruptive fevers, erysipelas, diphtheria, cachectic states, and similar conditions, so that their diagnostic value is thereby impaired. But when added to the other symptoms of typhoid, they are of value as an early diagnostic sign.

Russo's and Silvestri's reactions are frequently positive in typhoid, but are less constant and are met with in other diseases.

THERAPEUTIC VALUE OF BLISTERS.

At a recent meeting of the Bordeaux Medical and Surgical Society, Dr. Micheleau remarked that blisters, which are accused of numerous crimes and are being discarded in practice, still possess some therapeutic value. The reproach made that vesiculation produces nephritis, furunculosis, etc., is excessive. On the other hand, blistering offers numerous advantages. By this means one obtains an almost complete sedation of pleural pain, but it is not to be repeated as often as was formerly done. A blister the size of a silver quarter of a dollar is serviceable at the onset of a pleural collection, likewise when this is at its height or when the fluid is slowly absorbed. Dr. Micheleau thinks that when blistering has been applied, the patients were less exposed to the complications of tuberculosis.

Book Reviews

RECENT FRENCH LITERATURE.

Les Ulcères de l'Estomac et du Duodenum. By ENRIQUEZ and DURAND. Paris: Masson et Cie., 1923.

Clinique médicale. By CHARLES ACHARD. Paris: Masson et Cie., 1923.

La Chronaxie. By GEORGES BOURGUIGNON. Paris: Masson et Cie., 1923.

Les Ferments des Leucocytes. By NOEL FIESSINGER. Paris: Masson et Cie., 1923.

Les Processus de Désintégration Nerveuse. By IVAN BERTRAND. Paris: Masson et Cie., 1923.

L'Alcoolisme Cérébral. By R. BENON. Paris: G. Doin, 1924.

Les Grandes Syndromes Respiratoire. Fascicule I. By E. SERGENT. Paris: G. Doin, 1924.

Manuel de l'accoucheur. By DEMELIN and DEVRAIGNE. Paris: G. Doin, 1924.

Cancer du Rectum. By CHALIER and MONDOR. Paris: G. Doin, 1924.

Conférences de Clinique Médicale Pratique. By LOUIS RAMOND. Paris: Vigot Freres, 1924.

The authors of *Les Ulcères de l'Estomac et du Duodenum* have presented the diagnosis of these lesions in a clear and concise manner. The book is especially to be commended to the American reader, because the authors are not always in accord with the teachings of the American and English schools, in respect to the diagonsis of the seat of the ulcer by modern methods and their views on this point are highly interesting and deserving of much attention.

* * *

Prof. Achard, in his *Clinical Lectures,* of which there are twenty-eight in the present volume, describes in an interesting way the following morbid processes: staphylococcal septicemia; enterococcal septicemia of the rheumatoid purpuric type; puerperal infection; contagion of unrecognized scarlet fever; associated diphtheria; the clinical forms, pathogenesis and serotherapy of tetanus; purulent pneumococcal meningitides, pilous virilism, diabetes and Basedow's syndrome (five lectures). Other affections are also treated in the lectures, but the list given above will suffice to show the extreme interest of the book.

* * *

Dr. Bourguignon's book on *Chronaxia* is, if we mistake not, the first work comprising the entire subject. The author attacks the problem of measuring chronaxia through the integuments without exposing nerves or muscles and then adapts his technic to the study of man and animals in the normal and pathological states. It is evident that the study of chronaxia changes the point of view from which the study of the nervous system should be envisaged, and reacts on the manner by which diagonsis relating to the measure of the excitability should be established. Besides, the study of chronaxia brings forth certain indications with a precision heretofore unknown from the viewpoint of treatment.

* * *

Dr. Fiessinger's work on the ferments of the leucocytes is an important contribution to biochemistry and the result of fifteen years' labor. The application of ferments of leucocytes to general pathology illuminates certain phenomena which otherwise are difficult to understand, such as temperature, fever from absorption, resolution of pneumonic hepatization and exudates, homogeneization and tyrosinoreaction of the sputum, liquefaction of pus, the detersive process of wounds and their union, and antituberculosis defence of the organism.

By their study, one may establish a method of biological diagnosis, zymodiagnosis as it is termed by Fiessinger. Finally, modern theraputics becomes enriched from our knowledge of ferments of leucocytes in antiproteosotherapy, as well as general leucotherapy in affections of the nervous system, acute infections and tuberculosis.

* * *

The study of secondary degenerations plays a considerable part in the acquisition and progress of our knowledge relating to the central nervous system and Dr. Bertrand's book on *Les Processus de Désintégration Nerveuse,* is a decidedly important contribution to the subject. The processes of nervous disintegration are extremely varied and their various aspects are described in a masterly fashion by the author. The beautiful original illustrations in the text adds to the great value of the book and we can say unhesitatingly that Dr. Bertrand has performed a great service to all who are interested in the minute normal and pathological histology of the nervous system.

* * *

Dr. Benon, in his excellent work on *Cerebral Alcoholism,* shows how alcohol determines acute and subacute cerebral affections, as well as incurable chronic mental processes. Of the acute types, the author studies, first, alcoholic delirium which, in fact is a variety of acute toxic hallucinosis, hence the importance given to the description of the hallucinations; secondly, delirium tremens, or febrile alcoholic delirium; thirdly, alcoholic mental confusion, which is invariably episodic—never chronic; fourthly, Korsakoff's alcoholic psychosis, with its three fundamental syndromes, viz., fixation amnesia, jubulation and paragnosia, and the syndrome of dementia which is likely to be the terminal phase; fifthly, the alcoholic second state, and sixthly, deliriant and maniacal intoxication. As chronic cerebral forms, Dr. Benon first describes the mental state of the chronic alcoholic, dominated by disturbance of character: passion for alcohol—dipsothymia and dipsomania—and a tendency to anger and jealousy; secondly, early and late alcoholic epilepsy; thirdly, chronic systematized delirum, secondary to acute and subacute alcoholic hallucination deliria, and lastly, the chronic deliria of jealousy, with interpretation or hallucinations with or without terminal melancholia. We are inclined to regard this book as one of the best contributions to the subject that has so far appeared.

* * *

Prof. Sergent's treatment of the major respiratory syndromes will be complete in two volumes, the first of which has just been issued from the press. In it the author has grouped the major syndromes resulting, firstly, from lesions of the upper respiratory

ract and bronchi, and secondly, from the functional disturbances of the respiratory tract. Hence are discussed the syndrome of respiratory insufficiency, descending rhinobronchitis, asthma, the syndrome of chronic bronchitis and emphysema and bronchial dilatation. The book is essentially clinical, is by a highly esteemed authority, and is well worth perusal.

* * *

In their *Handbook of Obstetrics,* Demelin and Davraigne first give a very clear account of eugenesis and eutocia. The second part of the volume deals with dysgenesis, dystocia and pathology, with obstetrical operative technic. All the subjects are dealt with from the viewpoint of practice and theoretical explanations are only given for the comprehension of the phenomena and for the choice of the best treatment of accidents and functional disturbances. The book is illustrated with 465 figures and is unquestionably a reliable textbook.

* * *

Cancer of the Rectum, by Chalier and Mondor, is a thorough treatise on this important subject, written by two surgeons who have given long and careful attention to the question. The book is not only original as a general study of cancer, but gives—and this is most essential—a detailed account of the clinical difficulties and problems to be solved by the surgeon. The illustrations are excellent and, on the whole, this monograph is a solid contribution to the study of a very frequent malignant process.

* * *

And last, but not least, we have in the *Clinical Lectures* by Dr. Ramond, one of the best series of clinical instruction that has appeared in any language. The volume is the second series of lectures, the first having appeared last spring. The author has a surprising clearness in his writings which makes the perusal of the book a pleasure. The fifteen lectures comprising this series are: diabetic coma; pulmonary congestion; the diagnosis of ocular paralysis; diagnosis of chronic splenomegalia; cancer of the esophagus; tuberculous meningitis in the adult; perinephritic abscess; facial erysipelas; diagnosis of hemiplegia; peritoneopleural tuberculosis; gastric crises of pericarditis and Bright's disease; acute appendicitis; putrid pleurisies and lastly, alcoholic polyneuritides. We warmly commend these lectures to every practising physician familiar with the French language.

HEART DISEASE

Modern Methods in the Diagnosis and Treatment of Heart Disease. By Francis Heatherley. New York: William Wood & Company, 1923.

This excellent small volume, dedicated "to those who find salvation in compensatory hypertrophy and who fear a well conducted mitral," should be in the hands of every physician who has lacked the time and opportunity to keep himself informed of the progress of our knowledge during the last fifteen years concerning the heart and its disease. It is designed as a short, clear sketch of the present state of knowledge regarding heart disease, which might be useful to the general practitioner who is too busy to wade through all the recent literature on the subject.

In a clear, simple and convincing style the author discusses the importance of myocardial competency, the relative unimportance of murmurs, the significance of the irregularities, and the fallacy of the back pressure theory. In subsequent chapters he takes up the diagnosis of the arrhythmias, heart failure, symptoms and signs, and prognosis and treatment. The presentation is entirely clinical without recourse to instrumental methods, but is based on the knowledge that has been gained by the exact graphic methods for the study of the heart. Heatherley has succeeded in emphasizing the important facts and in eliminating nonessentials. Moreover, the text abounds in sound practical precepts, the fruit of solid experience. The case histories used for illustration are graphic and to the point.

The author is to be congratulated on having achieved more than he had planned. Not only will the book be of value to the general practitioner of the old school, but it will serve as a useful elementary text for the medical student, and as a model of lucid and sound clinical teaching to his instructors.

PROCTOLOGY

A Manual of Proctology. By J. Chittenden Hill, M.D. Philadelphia and New York: Lea & Febiger, 1923.

The purpose of Hill's book is to aid the practitioner and surgeon in the recognition and treatment of rectal diseases. While the author considers proctoscopy as an essential aid, he does not neglect the older methods of examination. Thus, with regard to a digital examination of the rectum, Hill expresses himself as follows: "Frequently, more efficacious than any instrument is examination with the index finger, covered by a thin rubber tissue cot, thoroughly lubricated with vaseline, and gently inserted. Often more examination is obtained by touch than by sight; for example, to the experienced examiner the feel of a growth means more than its gross appearance. It should always be borne in mind, however, that all manipulations, whether digital or instrumental, should be conducted in as gentle a manner as possible."

The differential diagnosis between benign and malignant strictures of the rectum are described in a lucid way, as follows: There are two forms of stricture—benign and malignant—and the only point of importance is the differentiation between these two. When a cancer has resulted in rectal stenosis, a mass of variable size can easily be made out both by digital and proctoscopic examination. On palpation, this gives the impression of a tumor much like the cervix uteri, except that it has a nodular feel and is often associated with invagination of the mass. The normal mucous membrane surrounding such invaginations gives them the smooth feel of a normal cervix.

A benign stricture of the rectum, on the other hand, when encountered at the anal orifice or at the level of the internal sphincter, can never be mistaken for anything else than an inflammatory stricture. At the anal orifice the overlying skin is tightly drawn down by scar tissue and will rarely admit the index finger. At the level of the internal sphincter there is an annular, banklike constriction. It almost feels as though a string were insinuated beneath the mucous membrane and tightly tied. Above this level

the stricture gives the sensation of passing one's finger into the mouth of a funnel. It is not nodular like cancer, but smooth and hard. In the tubular stricture there is quite a mass, but in the annular type this is not a feature. It is unusual to find an annular stricture more than a quarter to a half inch in thickness, so that the tumor effect is not well marked. This helps to differentiate it from cancer.

Hill's manual is practical and concise and will be of great value to both medical practitioner and surgeon.

DISEASES OF THE ALIMENTARY CANAL

Krankheiten des Verdauungskanals, des Pankreas und des Peritoneum. Zweite, vollkommen neu bearbeitete Auflage. Von Professor Dr. Carl von Noorden, Geh. Med.-Rat. in Frankfort a. M. Leipzig: Verlag von Georg Thieme, 1923. Pp. 107.

This brochure is No. 6 (entirely revised) of *Diagnostische und therapeutische Irrtümer und deren Verhütung, Innere Medizin,* edited by Schwalbe. A great many more diagnostic and, consequently, therapeutic mistakes are made in the handling of the diseases of the alimentary canal, pancreas and peritoneum than in that of any other system in the body. The establishment of a diagnosis frequently requires careful and painstaking study and investigation over an extended period of time. Very frequently the condition is seriously neglected for that reason. Only the most important mistakes that are likely to be made are discussed.

CHEMISTRY OF UREA

The Chemistry of Urea. The Theory of Its Constitution and of the Origin and Mode of Its Formation in Living Organisms. By Emil A. Werner, M.A., Sc.D., F.I.C. London: Longmans, Green & Co., 1923.

Since that famous day in 1828, when Wöhler accomplished the historic synthesis of ammonia with cyanic acid, urea has probably received more chemical attention than any other organic substance, because of its double importance, not only as an abstract chemical substance, but also as an anesthetic and as the great terminal excretory form of the nitrogenous residues of man, the higher apes, and Dalmation coach dogs. Volumes have been published on various phases of the relation of urea to human disease, but the chemistry has had to wait, and only now has been collected in monograph form. The writer has devoted much of his time to original research on the pure chemistry of urea, and has himself made important contributions to the theory of its structure. He is convinced that the older idea of the carbamide formula is incorrect, and that a cyclic formula is more consonant with the facts. The final decision must be left to the theoretical chemists. The text contains in addition to the purely theoretical discussion a very complete résumé of the properties of urea, its occurrence in nature, its decomposition and reactions. One of the most interesting facts is that the direct synthesis of carbon dioxide and ammonia can be obtained by passing these gases through a highly heated tube containing a suitable catalyst, so that the commercial production of large quantities of urea for fertilization seems to be one of the possible achievements of chemical engineering in the near future. A complete bibliography is appended to this valuable monograph.

REPRINTS FROM THE GEORGE WILLIAMS HOOPER FOUNDATION

Collected Reprints from the George Williams Hooper Foundation for Medical Research, Volume VII. University of California: 1922-1923.

This volume contains fifty reprints of papers which have appeared in various journals during the past year, from the Department of Research Medicine of the University of California Medical School. The first fifteen papers are sponsored by Whipple and his associates, and represent his studies on blood fibrin, röntgen ray intoxication, liver function, etc. It is interesting to have the recent publications of Alvarez gathered together in an easily accessible form. The last part of the book deals with the distribution of botulism in the United States, Alaska, Canada, China, the Hawaiian Islands, Belgium, Denmark, England, the Netherlands, and Switzerland.

A YEAR BOOK OF MEDICINE

The International Medical Annual: A Year Book of Treatment and Practitioner's Index. By Many Contributors. Forty-first Year. New York: William Wood & Co., 1923.

The forty-first issue of this well known *Medical Annual,* appears along the lines of last year's volume, which has met with considerable approval from the profession. The reader will be impressed by the fact that clinical diagnosis has been stressed by the various writers, as opposed to the more exclusive form of laboratory diagnosis, which has in a measure overshadowed the clinical aspects of medicine in recent years. In a volume so filled with excellent medical and surgical material, it is extremely difficult to select one or several for special mention. The best known physicians and surgeons of England, and a few from the United States, have contributed of their best to make this volume a most useful one to the internist as well as to the surgeon and the specialist. The text is liberally illustrated by forty-eight plates, some of them in color, and forty-three half tones in black and white. There is a vast fund of conservative yet up to date medical and surgical knowledge within the covers of this work, which cannot but prove to be most useful to the general practitioner and to the consultant. The publishers are to be congratulated on this excellent work.

PROCEEDINGS OF GERMAN PEDIATRIC SOCIETY

Monatsschrift für Kinderheilkunde. January-February 1923. Verhandlungen der dreiunddreissigsten Versammlung der Deutschen Gesellschaft für Kinderheilkunde in Leipzig, 1922. Im Auftrage der Gesselschaft herausgegeben von Prof. Dr. H. Brüning in Rostock, Schriftführer der Gesellschaft. Mit 26 Abbildungen im Text. Leipzig: Verlag von F. C. W. Vogel, 1923, pp. xxviii-360.

This entire double number of the *Monatsschrift für Kinderheilkunde* is devoted to the proceedings of the thirty-third meeting of the German Pediatric Society in Leipsic, 1922. It includes the papers by the leaders in German pediatrics and the discussion on nearly every aspect of pediatrics, such as the classification of nutritional disorders, gastric functional testing, hypogalactia, the utility of drawn mothers' milk, lactation, intestinal fermentation, nervous vomiting, transitory fever, atropin fever, dynamic albumin fever, nonspecific serum treatment, and many others too numerous to mention.

Medicoliterary Notes.

The Central Indiana Hospital for the Insane at Indianapolis has recently issued the eighth volume of the report of its departments of pathology and clinical psychiatry. One of the features of the volume is the inclusion of several interesting clinical papers by Dr. Max A. Bahr, clinical psychiatrist of the institution. These treat of the importance of a neuropsychiatric examination of registrants for military service, a case of multiple encephalomalacia with pathological demonstrations, a case of endothelioma of the brain, and prepsychotic manifestations in dementia precox.

* * *

The Smoke Inspector's Handbook, or Economic Smoke Abatement, is the title of a late publication by Lewis, of London. The author is Herbert G. Clinch, who, the title page tells us, is a certificated inspector of smoke, sanitation, meat and foods. Cyril Banks, medical officer of health of the County Borough of Halifax, writes the foreword in which he emphasizes the service such a study may render to the health officer and the health inspector from the point of view of the public health problem of smoke abatement and prevention.

* * *

It is time for some analyst to explain the present interest in animals and animal psychology, shown in so many recent works of fiction. Last year we had *Lady Into Fox,* by David Garnett, which won the James Tait Black Memorial prize for the best novel of 1923; *Claw and Fang,* by Ernest Glanville, a book just out, has in it a story the hero of which is a lion; and *Reynardine,* one of the stories in Don Byrne's volume, *The Changeling,* is about fox hunting. To cap the climax, we read that a French motion picture manager has, by dint of almost incredible patience, produced a film in which all the actors were animals, and, more recently, one in which animals and humans share the honors. Auguste, a chimpanzee, is the star, assisted by a company of apes, a few dogs, and some people.

* * *

The late Charles P. Steinmetz, according to a recent London announcement, has been posthumously awarded the prize of £1,000 by the trustees of the Franklin Fund, established in 1759 to reward authors of manuscripts or publications on the part played by the nervous system in the preservation and recovery of health. The treatise of Steinmetz that won the award was entitled The Nervous System as Conductor of Electrical Energy. Considering the comparative poverty in which the great electrician died, it seems almost a tragedy that this prize came so late.

* * *

The United States Navy replaces its familiar *Handy Book* with the *Hospital Corps Handbook* for 1923, a more complete and revised form of the earlier reference and guide book.

* * *

A new note was struck in the history of modern science when the German Colonial Society announced that it had discovered a remedy for sleeping sickness which it would give in exchange for the African colonies lost during the war. In spite of any justification which might exist for such a proposal, it certainly does not seem sufficient to offset the evil results of establishing a precedent by which medical discoveries for the benefit of humanity are kept secret for commercial exploitation.

* * *

A visit to Bernard Shaw is described most vividly and interestingly by Siegfried Trebitsch in a recent issue of the *Living Age,* taken from the Berlin *Vossische Zeitung.* Besides giving us entertaining bits about the great Irishman himself, the writer comments very pointedly upon *St. Joan* and *Back to Methuselah.*

* * *

Beggar on Horseback, a play by George S. Kaufman and Marc Connelly, is one of the cleverest and most entertaining of the comedies that have been produced in New York this season. The greater part of it shows the contents of a dream, and this gives opportunity for all sorts of surprising and absurd episodes. Roland Young impersonates the dreamer who wanders through the mazes of his dream, clad in dressing gown and slippers, in the most naïve and engaging fashion. Just about the time when the series of absurdities of the dream begin to pall a bit, an exquisite pantomime, with accompanying music by Deems Taylor, is introduced.

* * *

Another interesting play is *Cyrano de Bergerac,* with Walter Hampden in the title role. This has, perhaps, an excess of what might be called poetizing in it and could be cut to advantage, without destroying its charm and beauty as one of the most perfect examples of pure romance in literature.

* * *

In a recent literary review a writer, describing a visit to Petrograd, says: "It is no exaggeration to say that every third shop is a bookstore. Literature seems to have had a true renaissance in this city where until recently the population suffered terribly from famine."

* * *

A community mental health survey of Staten Island, New York, is being conducted by the Division on Mental Deficiency of the National Committee for Mental Hygiene. Dr. Edith R. Spaulding is directing this study.—*Mental Hygiene Bulletin.*

* * *

Stuart P. Sherman has in a recent number of *McNaught's Monthly* an article entitled Falling in Hate, a term with which he characterizes the love affairs of the modern heroine in Mid-Western fiction.

* * *

After All is the title of a recent novel by George F. Hummel, published by Boni & Liveright, dealing with the sex question. The author postulates as his explanation of the many unhappy marriages of intelligent and thinking men and women the fact that the two sexes have so widely different a conception of love. He offers no adequate solution.

* * *

One of the notable features of this season's theatrical productions seems to be the replacing of the time worn star system by an excellent caste throughout. This is especially evident in *Outward Bound,* by Sutton Vane, in which half a dozen of Broadway's leading actors and actresses are appearing. Although the interest of the play is almost wholly psychological, the lines and the acting are so clever that we are entertained and intrigued until the surprise at the very end.

* * *

Several of the member organizations of the National Health Council have been cooperating with the National Association of Book Publishers to arouse interest in the literature of health. A book promotion plan was advocated, providing that special emphasis on health books be given during February by libraries, book stores and publishing houses.

* * *

A probably unique morbidity record in experimental medicine was reported by Dr. Edward Francis, of the U. S. Public Health Service, in an address made recently before the Baltimore City Medical Society. In an investigation of tularemia, popularly called rabbit fever, the entire personnel of the Washington laboratory, including himself, contracted the disease. A culture was sent, with a warning, to the Lister Institute in London, where three persons at once became infected.

* * *

An interesting phenomenon in natural history occurring at present is the simultaneous appearance of man eating wolves in many regions of the world. The papers reported not long ago that packs of wolves had been seen for the first time since the Civil War period in northern New York and portions of New England. A large increase in the number of these marauders has been noted in Canada, in the Northern Provinces of which country many hunters and trappers have found it expedient to wear suits of heavy leather, with hat and gloves of the same material, all closely studded with outpointing nails and spikes. In Russia the wolf menace has become so great that all kinds of precautions and protective measures have been adopted by the peasants. This is partly due to the fact that the non-Soviet citizen is prohibited by law from owning or carrying firearms, so he has had to learn to depend on his knife or pitchfork, fire, and many kinds of baits and decoys for protection of his person and home.

Abstracts from Current Literature

CARDIOVASCULAR DISORDERS

Physical Findings in Pericarditis with Effusion.—Roger S. Morris and Carl F. Little (*American Journal of the Medical Sciences,* November, 1923) state that the cardiohepatic angle in pericardial effusion is usually acute; that the area of relative cardiac dullness in effusion is pyriform and generally extends upward to the first interspace; that widening of the area of dullness and of the shadow in the first and second interspaces occurs relatively early in effusion and is best determined with the patient in the recumbent posture; that shifting dullness, i.e., a narrowing of the dull area, with a corresponding decrease in width of the shadow over the great vessels when the patient is changed from the recumbent to the erect posture, has proved to be the most reliable physical sign of fluid in the pericardium; that widening of the dull area and of the shadow to right and left above the diaphragm when the patient is erect is found with fluid; that there is an absence or marked decrease of visible pulsation in the shadow fluoroscopically in pericardial effusion; that dullness at the angle of the left scapula is often present with a large accumulation of fluid in the pericardium.

Changes in the Blood Oxygen Following Therapeutic Bleeding in Cardiac Patients.—Samuel B. Grant (*Journal of Laboratory and Clinical Medicine,* December, 1923) describes a study of the blood of seven acutely decompensated cardiac patients, who were bled purely as a therapeutic measure. This produced an improvement in the peripheral circulation, as shown by a decrease in the coefficient of utilization of oxygen. When the arterial oxygen saturation was considerably below normal, and the heart not so seriously damaged as to be unable to respond to treatment, bleeding was followed by an increase in the arterial oxygen saturation, indicating improved efficiency of the pulmonary circulation.

Capillary Blood Pressure in Arterial Hypertension and in Nephritis.—Ernst P. Boas and Isidor Mufson (*Journal of Laboratory and Clinical Medicine,* December, 1923) report forty-five cases with arterial hypertension, in seventeen of which there was high capillary pressure. The mortality of these patients was much greater than that of those with low readings; eight of seventeen of the former, and five out of twenty-eight of the latter having died. The diastolic pressure is higher in patients with high capillary pressure. Nitroglycerine lowers both arterial and capillary pressures. One case of subacute nephritis out of over one hundred examined showed a high capillary pressure and a normal blood pressure. Autopsy studies brought out the fact that the pathological anatomy does not support Kylin's theory that a high capillary pressure is indicative of glomerulonephritis.

Insulin and the Blood Pressure.—P. Klemperer and R. Strisower (*Wiener klinische Wochenschrift,* September 20, 1923) show that ten units of insulin produce a transient reduction of blood pressure of about twenty to forty per cent. in cases of diabetes associated with hypertonia and increased blood pressure within two hours. In persons with a normal blood pressure (and also in diabetics) the reduction in blood pressure amounted to five to eleven per cent., which may be within physiological limits. If epinephrine solution is injected there results the typical increase in blood pressure irrespective of the previous or simultaneous injection of insulin. Experimentally, the blood pressure is not lowered by the insulin in normal rabbits in spite of hypoglycemia, and it is not lowered in cases of chronic nephritis with increased blood pressure.

A Simple Procedure for Ascertaining Circulatory Efficiency at Different Levels in Gangrenous Extremities.—A. Cosacesco (*Presse médicale,* September 26, 1923) notes that, with modern prosthetic devices, there remains practically no site of election for amputation in gangrene; the thing to be done is to amputate as low as is compatible with proper cushioning of the stump. To determine the proper level for amputation, he draws a fork or the back of a knife blade firmly over the tissues from above downward at various points. After a few seconds of pallor, the usual red vasomotor streak results; it may be accentuated by drawing a moist cotton pledget over it several times. The time of appearance, continuity, intensity and duration of the red streak at various levels is studied. It is late in appearing, absent, or broken up over segments of the limb no longer receiving a sufficient blood supply. Comparative inspection of the line from one end to the other and on all four, or at least the two lateral, aspects of the limb gives a good idea of what circulation remains. The sign always proved satisfactory. At times it definitely showed that amputation could be carried out lower down than had been thought, and in no case was reamputation later necessary, the flaps always having sufficient vitality. No conclusion is to be reached from the test, however, as to the exact level of obstruction in the main arterial trunk; generally the obliterated point is higher up.

Ventricular Complex of Electrocardiogram as a Physical Sign in Cardiac Prognosis.—J. E. MacIlwaine and S. B. Boyd Campbell (*British Medical Journal,* September 15, 1923) show how remarkable the "T" negativity or inversion of the "T" wave is as a prognostic sign of great value. The possible fallacy of the inversion being due to digitalis is excluded.

GYNECOLOGY AND OBSTETRICS

Uterine Curettage: Its Multiple Contraindications and Limited Indications.—Eugene St. Jacques (*Canadian Medical Association Journal,* November, 1923) thus sums up a very vigorous paper:

In chronic metritis usually accompanied by malposition of the uterus and salpingitis, curettage is of no avail and rather harmful. In the dysmenorrhea of the noninfected woman it is equally noneffective; other means must be resorted to. In acute infections following miscarriage or delivery, only in very exceptional cases is curettage to be done, and then in a very delicate manner to remove intrauterine necrotic débris; other therapeutic means are to be associated. In the hemorrhagic class of cases, curettage may be advised. In cancer for microscopical research, and precision of diagnosis only; in very advanced cases the specialist may be called upon to curette and destroy vegetations too hemorrhagic and offensive. These are exceptional cases. In hemorrhage caused by tumors, such as fibromyomata, curettage is seldom harmful but seldom useful. In fact curettage seems to have its principal indications in two classes of cases only; for microscopical examination in doubtful cases of cancer of the corpus uteri, and for remedying profuse and continuous hemorrhage consecutive to delivery or miscarriage. In other instances it is usually useless and generally harmful.

Innervation of the Uterus.—Beckwith Whitehouse and Henry Featherstone (*British Medical Journal,* September 8, 1923) show that the nervous mechanism controlling the uterus consists of three systems; namely, local, sympathetic, and lumbosacral autonomic. The local system can produce rhythmical uterine contractions, and is independent of the sympathetic and autonomic systems, in common with other involuntary muscle. The sympathetic stimuli are motor to the circular muscle fibres and inhibitory to the longitudinal bundles. The lumbar cord stimuli are motor to the longitudinal fibres and inhibitory to the circular fibres. Both autonomic and sympathetic stimuli are controlled by higher centres in the medulla and possibly by the cortex, but are capable of acting independently of the same. Reflexes, both autonomic and sympathetic, are probably important factors in normal uterine contraction. Uterine contractions, to be effective, depend equally upon the integrity and correctly adjusted balance of autonomic and sympathetic impulses. Disturbances in either, whether in the direction of augmentation or diminution, will interfere with the normal course of parturition.

In classical Cæsarean section the advantages of lumbar narcosis, either alone or combined with a general anesthetic, are evident. By elimination of inhibitory stimuli from the lumbar cord and allowing the hypogastric impulses full play, the circular muscle fibers of the uterus contract firmly, and in so doing reduce hemorrhage to a negligible amount. The contraction of the circular fibers also produces more marked eversion of the edges of the uterine incision than occurs normally, and consequently the introduction of the uterine sutures and accurate coaptation of the

cut surfaces is facilitated. When a temporary increase of intrauterine tension is indicated, as in antepartum hemorrhage from premature separation of a normally situated placenta, this may be obtained without risk of inducing labor by means of lumbar cocainization. With placenta previa, although the hemorrhage might be controlled temporarily by contraction of the lower uterine segment, it probably would be increased subsequently, owing to greater separation of the placenta. When the uterus is exhausted, the spinal anesthesia will undoubtedly lessen the tendency to postpartum hemorrhage. For the same reason spinal is preferred to general anesthesia when it is necessary to evacuate the uterus by the vaginal route during the earlier months of pregnancy. Tonic uterine contraction during labor, either general or local, as in the contraction ring and socalled rigid cervix are due to excessive sympathetic stimulation, probably from fatigue of the lumbar centre. Spinal anesthesia should not be used in normal cases of labor, as with it dilatation of the cervix is delayed and the expulsive power of the uterus is diminished and forceps will probably be required.

Indications and Technic of Intrauterine Tamponing.—Emil Eckstein (*Zentralblatt für Gynäkologie,* September 1, 1923) believes that intrauterine tamponing is useful chiefly in checking hemorrhage in anemic women in cases of febrile abortion when emptying of the uterus is impossible. The gauze keeps the cervical os patent and the fetal remnants are removed together with the gauze. The gauze may be left for three to four days after the subsidence of the fever. The indications are the following: In profuse uterine hemorrhages which must be controlled quickly, regardless of whether the cause is uterine disease or retained secundines; retention of secundines with continuous profuse hemorrhage, often for several weeks; in induced abortion from the first to the fifth month; in hemorrhages from postpartum atony of the uterus; retention of secretions postpartum or after abortion, and in febrile abortion, instead of all other forms of treatment, when the retention of secundines cannot be definitely eliminated. It is contraindicated in febrile inflammatory disease of the adnexa and the pelvic peritoneum, owing to the displacement of the uterus and the adnexa as the result of the manipulation.

Treatment of Urethral Gonorrhea in the Female.—Ernst Vey (*Zentralblatt für Gynäkologie,* July 14, 1923), recommends the following line of treatment for urethral gonorrhea in the female: with the aid of a Kelly speculum up to size No. 8 the urethral mucosa is sufficiently dilated without injuring the epithelium and the sphincter muscle and all the folds in the mucous membrane are ironed out. The exposed mucous membrane is then cauterized two or three times at intervals of eight to ten days after sufficient dilatation is secured. It is immaterial what remedy is used for local application, as the results are pretty much the same with silver nitrate, collargol, trypaflavine, and similar preparations.

Physiology of the Placental Bloodvessels.—Walther Schmitt (*Zentralblatt für Gynäkologie,* July 22, 1922) was enabled to show that the bloodvessels of the placenta respond to the influences of temperature, electrical stimulations, histamine, and barium chloride in the same manner as do the bloodvessels of the other organs in warm blooded animals. However, a difference was noted in regard to the action of adrenalin on the bloodvessels of the placenta. This difference leads to the assumption that the anatomical point of attack of the stimulation by adrenalin in the vascular wall differs from that of other stimulations. The great sensitiveness of the placental vessels toward oxygen produces a certain vasodilatation and a displacement of the oxygen, either by carbonic acid or nitrogen, leads to relaxation of the bloodvessels. These facts are of great significance. The author suggests that the dilatation of the vessels in the placenta is controlled by the oxygen and through it the amount of blood circulating through the placenta is regulated. When the pressure of the oxygen sinks, the vessels dilate, more blood circulates through the placenta, and more blood is arterialized, regardless of whether the oxygen exchange between the mother and the child is the result of diffusion or of oxidizing ferments in the placental tissue. If the fetal blood is saturated with oxygen, resulting in a rise of the oxygen pressure, the vessels contract, the amount of blood circulating in the placenta is diminished, and the rapidity of the blood current is increased. These constant variations in the dilatation of the placental bloodvessels provided not only a constant supply of oxygen to the fetus but through it an active propulsion of the fetal blood stream results. This is significant because the placental bloodvessels are not controlled by vasodilators and vasoconstrictors emanating from the central nervous system. The control of the placental bloodvessels is autonomous and the respiratory centre of the fetus is located, as it were, in the placental bloodvessels.

The Significance of the Bacteriological Examination of Lochia in the Treatment of Febrile Uncomplicated Abortion.—As a result of his investigations, Carl Meili (*Schweizerische medizinische Wochenschrift,* September 6, 1923) maintains that the bacteriological examination of the lochia in determining whether a patient afflicted with febrile abortion should be subjected to a conservative or active treatment. If streptococci and liquefying staphylococci are not found in the cavity of the uterus, the ovum or its remains can be removed operatively without injury to the patient. In this way the duration of the condition may be considerably shortened. If, however, the organisms described above are found, the operative removal should be avoided during the febrile stage, and the patient should be treated conservatively as long as the fever persists.

Treatment of Puerperal Tetanus with Intracranial Injections of Serum.—K. Fritsch (*Zentralblatt für Gynäkologie,* September 8, 1923) does not believe that the treatment of puerperal tetanus is futile. He recommends the subdural injection of about five c. c. of tetanus antitoxin (of a solution of 100 antitoxin units) under local anesthesia given through a trephine opening, together with subcutaneous injections and lumbar puncture and the injection of about fifteen c. c. of antitoxin, as well as the administration of enemas of ten c. c. of a twenty per cent. magnesium sulphate solution three times daily.

Studies on the Corpus Luteum of Pregnancy in the Cow.—August Kaltner (*Zentralblatt für Gynäkologie,* September 8, 1923) studied the evolution and involution of the corpus luteum in slaughtered cows. He found that in 295 of 300 cows examined the number of corpora lutea agreed with the number of fetuses in the uterus; in the remaining number there was an excessive number of corpora lutea. In every case the corpus luteum appeared in that particular ovary which was connected with the gravid uterine cornu by its fallopian tube. In no case was the migration of the ovum demonstrable.

Treatment of Perforation of the Uterus.—E. Schwab (*Zentralblatt für Gynäkologie,* September 8, 1923) believes that conservative treatment of perforation of the uterus with rest in bed, icebag, and opium is indicated only under the following conditions: when the perforative injury is slight; in the absence of infection; when there is only a slight possibility of bacterial infection from a decomposed placental tissue; when hemorrhage into the abdominal cavity is slight, and when the presence of a secondary lesion, as in the intestine, bladder, ureter, or a fair sized bloodvessel can be definitely excluded. Active interference is indicated when the conditions mentioned are not found. A delay may result in serious consequences to the patient.

Bladder Stone as a Hindrance to Delivery.—Wolfram Boetticher (*Zentralblatt für Gynäkologie,* July 15, 1922) reports the following case: In a para II, thirty-six years old, the vaginal introitus appeared constricted during the delivery by a bony protrusion which pushed the anterior vaginal wall forward. The protrusion, which was not movable and seemed to spring from the symphysis, was taken for an exostosis. On applying the forceps, a stone as large as a small hen's egg was pushed through the anterior vaginal wall with the delivery of the child and a vesicovaginal tear resulted. The subsequent fistula required several plastic operations for its cure.

Treatment of Severe Uterine Hemorrhage by Radium.—Sidney Forsdike (*British Medical Journal,* September 8, 1923) asserts that radium arrests uterine hemorrhage solely through its action on the endometrium. A prolapsed ovary lying near the uterus would be diagnosed, and, if the condition of the patient was imperative, the exposure to radium would be given with the certainty that the ovary was going to be affected, whereas any mass felt which might bear the interpretation of chronic pelvic peritonitis would be an absolute contraindication, for pelvic inflammation finally negatives the use of radium.

CLINICAL MEDICINE

Studies on the Enzymes of Pneumococcus.—O. T. Avery and Glenn E. Cullen (*Journal of Experimental Medicine,* August, 1923) state that pneumococci possess an active intracellular agent which has the property of causing lysis of the bodies of heat killed pneumococci. The lytic agent is not type specific, since strains of pneumococci serologically different are equally affected. The bacteriolytic enzyme of pneumococcus also possesses to a considerable degree the ability to attack streptococcus of the viridans type. The lytic action of the enzyme was evident in the zone pH. 5 to 8. The action of the intracellular bacteriase is directly proportional to the concentration of the enzyme. Exposure in the water bath to a temperature of 60° C. for 30 minutes destroys the activity of the bacteriolytic enzyme of pneumococcus.

Studies on Pneumococcus Immunity.—Russell L. Cecil and Gustav I. Steffen (*Journal of Experimental Medicine,* August, 1923) were able to demonstrate a complete immunity in monkeys against experimental pneumococcus Type II pneumonia by three subcutaneous injections of pneumococcus Type II vaccine. Likewise protection against pneumococcus Type IV pneumonia was obtained by three subcutaneous injections of vaccine prepared from the same strain of pneumococcus. Only four of eight monkeys vaccinated with three doses of pneumococcus Type III vaccine were protected. The subcutaneous injections of pneumococcus Type II, III, and IV vaccine failed in every instance to produce protective substances in the blood, even when the monkey was immune to infection. William A. Perlzweig and Gustav I. Steffen believe from the experiments reported that the pneumococcus antigen is nonlipoidal, that it probably adheres to the protein fraction in a loose chemical or physical union, rather than representing a protein complex of a large molecular size, as shown by its solubility in alcohol, its thermostability and its resistance to proteolytic digestion.

Significance of Nitrogen Estimations in the Blood in Arterial and Kidney Disease.—Jesse Levy (*Journal of Laboratory and Clinical Medicine,* December, 1923) has attempted to correlate the nitrogen estimations in the blood (antemortem) with the postmortem findings in the kidney. He states that technically though diffuse destruction of the glomeruli is the only renal cause for a nitrogen retention in the blood, it has been shown that the structureless kidney of a chronic glomerulitis, characterized by diffuse disease of the glomeruli, should be so regarded. All kidney pathology dependent upon a primary arterial disease influences the nitrogen metabolism in an indirect way. It is the added burden of kidney pathology which makes the kidney a factor. In the decrescent and intermediary types, the insult to the circulation is a variable one. In the precapillary type, kidney pathology uniformly causes a nitrogen disturbance, and the socalled structureless type is always accompanied with high retentions. Neither structural changes in the kidney independent of their origin, nor diffuse disease of the tubules, can be regarded as a direct source of a nitrogen disturbance. Amyloid disease of the glomeruli only when completely destroying the tuft induces a nitrogen retention.

Glucokinin: An Apparent Synthesis in the Normal Animal of a Hypoglycemia Producing Principle.—J. B. Collip (*Journal of Biological Chemistry,* November, 1923) reports that the blood of a rabbit, dying with hypoglycemia as a result, either direct of indirect, of previous inoculations with a plant extract, is capable of producing profound hypoglycemia and death when such blood is injected into other normal rabbits. When normal rabbits are so inoculated and later die with hypoglycemia the blood of these animals has similar properties. Animal passage would seem to be possible to an indefinite degree. An organism as the causative agent is improbable. The characteristic symptoms, low blood sugar, extreme weakness and general atonia, and convulsions, may be antidoted temporarily by the administration of glucose, but the ultimate fatal issue has not been offset as yet by such a procedure. The following observations are recorded with regard to the nature of the hypoglycemia producing principle: it is active after autoclaving at fifteen pounds pressure. It can be dialyzed. Watery solutions can be concentrated by boiling over a free flame. It is present in the filtrate obtained after treating passage blood with tungstic acid, and it can be removed from passage blood by ammonium sulphate. A lethal dose for a full grown rabbit may be contained in 0.05 c. c. of passage blood.

Variations of the Percentage of Hemoglobin in Man During the Day.—I. M. Rabinovitch (*Journal of Laboratory and Clinical Medicine,* November, 1923) reports observations on twenty individuals in whom the hemoglobin was determined at two hour intervals from 8 a. m. to 6 p. m. Although in a few instances the variations ranged within narrow limits, two cases showed as much as 26 per cent. variation, in four it was from fifteen to twenty per cent., and in six, from ten to fifteen per cent.

On the Phosphorus Compounds in Normal Blood.—Mary V. Buell (*Journal of Biological Chemistry,* May, 1923) states that in normal dog's blood certainly, and in human blood probably, the inorganic phosphates are confined to the plasma and the organic phosphates to the corpuscles. This point of view is not in keeping with the statement that the concentration of inorganic phosphate of serum and of whole blood in fresh specimens is identical.

Formaldehyde-Gel Reaction in the Diagnosis of Syphilis.—Robert A. Kilduffe (*Journal of Laboratory and Clinical Medicine,* March, 1923) compared the formaldehyde-gel reaction of Gate and Papacostas with the Wassermann reaction in a series of 480 sera. Of these, 80 gave positive Wassermanns. With the formaldehyde test 170 were positive; of these only forty occurred with the Wassermann positive sera, the reaction being entirely negative with fifty per cent. of the Wassermann plus sera. Of the 400 sera negative to the Wassermann test, 130 gave positive formaldehyde reaction. It is obvious that the formaldehyde-gel reaction will give negative results in syphilis, and positive results in the absence of it in a sufficiently high number of cases to make it extremely unreliable as a means of diagnosing that disease. The test should therefore not be used for the purpose.

Electrolyte Content of the Red Blood Corpuscles. The Findings in Chronic Anemia and Polycythemia.—Thomas E. Buckman, W. Richard Ohler, and Louise L. Doherty (*The Journal of Medical Research,* September 1923.) The cases studied include only those in which the plasma volume was within normal limits, and comprised seven normal men, nine patients suffering from severe, long standing anemia, five persons showing a mild degree of chronic anemia, and four individuals showing a chronic erythrocytosis. The results obtained indicate a relationship between the electrolyte content of the corpuscles as measured by the specific conductivity of a clear solution of their products of hemolysis and the concentration of the corpuscle in the peripheral blood as measured by the hematocrit. The specific conductivity of the blood serum is almost a constant. In the cases reported, the electrolyte content of the corpuscle was proportional to the per cent. volume of the corpuscles.

Studies in the Physiology of Muscular Exercise.—David P. Barr (*Journal of Biological Chemistry,* May, 1923) obtained a continuous record of the volume of respiration of four normal men before, during, and after exercise, corresponding to approximately 3500 kilogram metres in three and one half minutes, and studied the blood reaction of three of them accompanying exercise. No constant relationship between reaction and respiration can be demonstrated from these observations. Following exercise, when the minute volume was rapidly decreasing, the acidosis of the arterial blood remained essentially the same or even decreased. A study of the literature shows that evidence has accumulated which indicates that the reaction of the blood does not furnish as specific and delicate control of respiration as was originally supposed.

On the Existence of More than Four Isoagglutinin Groups in Human Blood.—C. G. Guthrie and J. G. Hu (*Bulletin of the Johns Hopkins Hospital,* April, 1923) examined blood from two hundred persons during three months, performing 1282 macroscopic and 3570 microscopic tests. The results of this work have led them to believe that the classification of blood groups is not so simple nor the number of groups so limited as has generally been believed. This last paper of the series contains a summing up of their conclusions, among which may be mentioned the following: The presence of only two isoagglutinins and two isoagglutinogens in human blood is inadequate to explain their findings. By direct tests and by absorption experiments, the existence of a third isoagglutinin and a third isoagglutinogen has been demonstrated. Although recognizing the possibility that there may be still other isoagglutinins and isoagglutinogens in human blood, the

have found nothing so far to indicate their existence, but their observations have shown that there are *at least* three of each. With three isoagglutinins and three isoagglutinogens there are twenty-seven combinations biologically possible. It is believed that these findings have a practical bearing upon transfusion and furnish a plausible explanation for some of the hitherto unexplained posttransfusion reactions. Allowance has been made for the possible occurrence of autoagglutination, which it is believed has not been a complicating factor in the results. The grouping of blood should be determined on a basis of their agglutinin-agglutinogen content. Only bloods with the same agglutinin-agglutinogen content belong to the same group. Methods for the classification of blood groups are suggested.

Inorganic Salt Metabolism.—E. G. Gross (*Journal of Biological Chemistry,* April, 1923) produced tetany in dogs, and marked changes in the ionic balance by the subcutaneous injection of sodium oxalate. Citrate did not produce these changes. The sodium, chlorine and calcium are decreased, the first two in about the same proportion, while the phosphorus and potassium are increased, also in about the same proportion. The magnesium was uninfluenced.

NEUROPSYCHIATRY

Drug Therapy of Anxious States.—Ludwig Stein (*Wiener klinische Wochenschrift,* August 30, 1923) proceeds from the premise that anxious states are due to a hyperemia of the subcortical centres of the brain, and he, therefore, endeavors to correct these suspected circulatory disturbances. As a matter of fact, he obtained good results with cardiac tonics, especially digipuratum, in several cases. The most striking results were obtained in a case of a severe psychosis of anxiety with 0.0005 gram of nitroglycerin.

Decompression and Ventricular Puncture.—J. A. Barré and P. Morin (*Paris médical,* October 6, 1923) find that in decompression operations the pressure of the cerebrospinal fluid begins to fall while the first trephine opening is being made and before there has been any actual osseous decompression. It continues to fall rapidly throughout the first stage of the operation and shows but little accentuation when the piece of skull is actually removed. Nevertheless, the total reduction of cerebrospinal pressure is not marked unless the dura is opened; the pressure may remain decidedly high in spite of the operation. The operation relieves the headaches as long as the dura is sufficiently dilated or distensible to deaden the attacks of hypertension, and does this in spite of the average tension remaining high. In view of the fact that the tension may remain dangerously high in spite of the fact that the patient seems out of danger, it is very useful, to avoid a false sense of security to make determinations of the cerebrospinal pressure during the operation and a few days later. In cases exhibiting pressure manifestations alone, without localizing signs, it seems best to give preference to ventricular puncture—followed by drainage if necessary—over an extensive decompression operation which, even in the most favorable cases, leaves the patient's skull defective. Or, ventricular puncture and decompression may be combined where this seems indicated.

Effect of Time Between Obtaining a Spinal Fluid and Making a Cell Count on the Result of the Count.—James Wynn (*Journal of Laboratory and Clinical Medicine,* February, 1922) counted eighty spinal fluids at varying intervals up to fifteen hours. The cells in clear spinal fluids, collected in clean tubes and tightly stoppered, may safely be counted at the end of that time, if thoroughly mixed, and in the absence of macroscopic pellicle, sediment or web. Whether the tubes are kept at room temperature or in the ice box makes little difference. In two cases of meningitis the thorough mixture of small quantities of powdered sodium citrate with the fluids made it possible to duplicate the original cell counts within the limit of technical error at three and fifteen hour intervals. However, this procedure must be tried in a large series of cases before any conclusions are warranted concerning such citrating of fluids.

Cause of Socalled Idiopathic Hydrocephalus.—Walter E. Dandy (*Bulletin of the Johns Hopkins Hospital,* March, 1921) presents this article to establish proof of the cause of communicating hydrocephalus, i. e., of the type in which all the ventricles are in communication with the arachnoid space. During extensive studies on the absorption of cerebrospinal fluid in hydrocephalus it was found that in the communicating type the absorption from the subarachnoid space was greatly reduced. A reduction in the amount of the absorbing spaces which are reached by the cerebrospinal fluid was suspected as the cause and a hypothetical pathology was suggested along this line of reasoning. Later, a study of four cases of communicating hydrocephalus at necropsy showed that in each adhesions were found which obliterated the cisternæ, therefore it was assumed that by preventing the cerebrospinal fluid from reaching the great absorbing spaces over the cerebral hemispheres, these adhesions had caused the hydrocephalus. From his study Dandy comes to the following conclusions: The cause of communicating hydrocephalus (the remnant of socalled idiopathic hydrocephalus) is an obstruction in the cisternæ which has been conclusively demonstrated in three ways: 1. Experimentally communicating hydrocephalus can be produced by blocking the mesencephalic cisterna. 2. The obstruction can be graphically demonstrated in the experimental animal or at necropsy in the human by injecting a suspension of India ink into the spinal canal; the color stops abruptly at the obstruction. 3. In all living patients the obstruction can be clearly shown by cerebral pneumography after air has been injected into the spinal canal; the air also stops at the obstruction, and can be sharply outlined in the röntgenogram. The obstruction in the subarachnoid space is most frequently located in the mesencephalic or pontine cisterna. However, the obstruction need not necessarily be in the cisternæ; it may be in the large branches which carry the fluid from the cisternæ chiasmatica and intrapeduncularis to the cerebral sulci. Any number of these branches may be occluded. If all the main branches are obstructed, the hydrocephalus will be the same as if the occlusion were in the cisterna. If some of the branches remain unobstructed, the degree of hydrocephalus will be modified proportionately; a complete cure may even result because of the absorption which takes place in the remaining patent areas of the subarachnoid space. Adhesions following meningitis and occluding the cisternæ cause the vast majority of cases of communicating hydrocephalus, and many cases of obstructing hydrocephalus by blocking the foramina of Luschka and Magendie. Adhesions give infallible proof of a preexisting meningitis. In two cases the hydrocephalus appeared to be due to a congenital failure of the cisterna or of its branches to develop. Tumors in the pons, medulla, or mid-brain also produce partial or complete obstruction of the subarachnoid space and therefore cause communicating hydrocephalus.

Space Compensating Function of Cerebrospinal Fluid; Its Connection with Cerebral Lesions in Epilepsy.—Walter E. Dandy, (*Bulletin of the Johns Hopkins Hospital,* August, 1923) observed the brains in a series of seventy-five epileptics at operation, exclusive of a large series of cases in which convulsions occurred in patients with brain tumors, abscesses, foreign bodies, etc., from a study of which he presents evidence of the frequent presence of gross organic lesions in epilepsy. The changes that may be detected before or during the operation are dilatation of the ventricles, abnormally shaped ventricles, dilatation of the subarachnoid spaces, softening of the brain (atrophy), areas of increased density (fibrosis or gliosis), and changes in the meninges. The author believes that these are evidence of actual cerebral lesions (end products of repair), and their frequent finding has led him to the conclusion that there is a pathological basis for socalled idiopathic epilepsy in a large proportion of the cases. This view is confirmed by ventriculography, which in a certain number of cases shows acquired or congenital distortion of the ventricles.

Hysterical Fits and Their Treatment.—Lewis R. Yealland (*Lancet,* September 15, 1923) states that a diagnosis between hysterical fits and epilepsy is difficult and sometimes impossible if no seizure is witnessed. Although hysterical fits have been produced by suggestion aided by electricity, the latter is certainly not necessary and the need of the former is doubtful. These fits have been produced by simple passive resistance against movement of a limb. An attack seems always to follow a certain state of tone of the muscles, which is created by simultaneous contraction of agonists and antagonists. Cloniclike movements occur in many neurasthenic individuals subjected to passive resistance and these show the same distressed facial expression. This test is of considerable diagnostic importance and is easily elicted. The treatment is symptomatic and the period of freedom from the attacks has been found to vary between five years and six months. The recoveries amount to about sixty per cent.

Medicolegal Notes.

REFUSAL TO TAKE PHYSICIAN'S ADVICE

As a result of holding cloth taut and straight while it passed over a roller, a blister developed on an employee's thumb and broke, and shortly afterwards the thumb became infected. She went to the employer company's doctor, who treated her, and asked her to take a certain course of treatment, including lancing the thumb, which she refused to do. She subsequently went to her own family doctor, who put on antiseptic dressings, and, finding the thumb badly inflamed and in a serious condition, advised making an incision to drain the pus. This she would not allow, and consulted the insurance company's physician, who, after taking an x ray, told her she should have the thumb partly amputated, which she also refused to allow.

The Illinois Supreme Court, Western Shade Cloth Co. v. Industrial Commission, 308 Ill. 554, 140 N. E. 45, holds that the injury was an accident, traceable to the employee's work, but that she should not have been allowed to recover for permanent loss of seventy per cent. of the use of the thumb without some showing that the permanent loss was not caused by her nelecting to follow the advice of the physicians. It was reasonable to assume that if she had accepted their advice and taken the treatments the injury would not have been as serious as it turned out to be.

TUBERCULOSIS HELD PERMANENT DISABILITY WITHIN MEANING OF INSURANCE POLICY.

The New York Appellate Division holds, Ginell v. Prudential Ins. Co., 200 N. Y. Supp. 261, that tuberculosis is a permanent disability within an insurance policy against "permanent disability," which provides that if the insured recovers from such state of disability no further payments shall be made by the insurer. "In using such language the parties must have understood that the disability, though permanent, might not continue. The inexorable inference to be drawn as to the meaning of 'permanent' is that it is applicable to a condition of disability which, while not transient or ephemeral, still may pass away.

"The sense in which the word 'permanent' is used in the policy is that of its Latin derivation—*per*, through; *maneo*, to remain. The policy covers disease in which disability may remain. Tuberculosis is such a disease. It is difficult to say whether its arrest may be accomplished. It is a fixed disease, permanent in its nature, and involving permanent or fixed incapacity in its victim to work for a long period of time at best."

Two judges dissented on the ground that the policy should not be construed to include tuberculosis as a permanent disability.

EXPERT OPINION AS TO WHETHER ACCUSED USED MARIHUANA PRECEDING HOMICIDE HELD INADMISSIBLE.

In a prosecution for murder it was suggested by the defense that accused was a marihuana smoker and that from the effects of this drug he had developed a homicidal mania. It was a testimony by a physician that the use of marihuana in excessive quantities would produce a state of mind similar to delirium tremens, and he said that if accused was under the influence of that drug at the time of the homicide, in his opinion he would not know the right or wrong of the act charged against him. There was evidence that on the night preceding and four days before the homicide, accused had smoked cigarettes, which "did not look or smell like good tobacco," and that fifteen years before he had asked witness to get him some marihuana.

Accused then placed another medical witness on the stand, who testified that he had observed the effects on persons of the use of marihuana. The facts attending the homicide were then stated to him, as well as the testimony as to accused's smoking cigarettes, and he was then asked, assuming such testimony to be true, would he conclude therefrom that the cigarettes smoked on the night preceding the homicide were marihuana or not. The State's objection to this testimony was sustained by the trial court. The Texas Court of Criminal Appeals holds, Cadena v. State, 251 S. W., 225, that the testimony was inadmissible. The doctor as an expert witness could state what condition of the mind would follow the use of marihuana. The fact of the use of such drug, and the amount and quantity of such use, could be proven by witnesses who knew such facts. But expert opinions must be limited to matters of science, skill, trade and the like, and will not be allowed to usurp the province of the jury on matters of fact of which the jury are made the judges by law.

PHYSICIAN'S TESTIMONY ADMISSIBLE THAT WOUNDS COULD HAVE BEEN CAUSED BY WEAPON IN HANDS OF MAN.

On a murder trial, where the defendant was accused of striking the deceased, a woman, with a chair, a physician who had qualified as an expert was permitted to testify that, from his examination of the wounds or discolorations found by him on the deceased's body, these could have been made by a chair with a board nailed on the front an inch thick and two or three inches wide, in the hands of a man such as the accused. The Texas Court of Criminal Appeals, Perison v. State, 251 S. W., 1092, held this no error, since the question as to whether the injury could have been inflicted by the chair was not one of which the jury were as competent to judge as the physician.

MUNICIPAL HOSPITAL NOT LIABLE FOR EMPLOYEE'S NEGLIGENCE.

The Tennessee Supreme Court, Wallwork v. City of Nashville, 251 S. W., 775, follows the authorities in holding that a charitable municipal hospital is exempt from liability due to the negligence of its employees, even when fees were paid by the patient. The negligence alleged was the placing of a scalding hot water bottle in the patient's bed by hospital employees before she recovered from the effects of an anesthetic while undergoing an operation, severely burning the patient's feet. There was no claim that the city and hospital commissioners did not exercise ordinary care in selecting the employees.

MEDICAL WITNESS TESTIFYING THAT FROM EXPERIENCE MEANS FROM PROFESSIONAL EXPERIENCE.

In a personal injury case where the principal injury was to the plaintiff's knee, the attending physician found the knee swollen and very painful to the touch. In his opinion, one or more of the ligaments had been strained or turned. Speaking from experience, he said that the knee joint, when once hurt, remains more or less weak. In doing straining work, it becomes painful and loses a part of its mobility. According to his best judgment, the injury to plaintiff's knee would be likely to last through his life. On the other hand, the physicians who testified for the defendant company said that plaintiff's knee had been completely cured. It was insisted for the defendant that because the attending physician used the words, "I am speaking just from my experience," his evidence was of no greater value than that of a layman. The Kentucky Court of Appeals, however, in American Ry. Express Co. v. Lancaster, 251 S. W., 670, held that it was evident that the witness spoke from his experience as a physician and that such experience would add weight to, rather than detract from, the value of his testimony.

Certain Aspects of Focal Infection Commonly Misunderstood*

HERMON C. BUMPUS, JR., M.D.,
Rochester, Minn.,
Section on Urology, Mayo Clinic

The various diseases referable to focal infection, and demonstrated experimentally to be the result of elective localization of streptococci, are so extensive as to embrace almost every field of medicine. It is, therefore, of paramount importance that the general practitioner as well as the specialist, should be cognizant, not only of the more important facts relating to pathological changes, but of the special methods of experimental investigation employed.

When the etiology of a certain disease suspected of being referable to focal infection is investigated, the procedure is not, as one might suppose, to obtain from the focus pure cultures of the various types of bacteria present, and by injecting these into experimental animals, ascertain which will reproduce the disease. Instead, all the bacteria are collected and injected into experimental animals, and if the disease under investigation is reproduced, the causative organism is then obtainable from the lesion produced. Thus the animal, acting as a filter, conserves the infinite time and patience that would be necessary to culture and subculture the original mixed focus in order to obtain pure strains. More important than the saving of labor is the fact that many bacteria are extremely sensitive to various degrees of oxygen tension, and if the usual cultural methods of plating on blood agar and isolating the suspected microorganism in pure culture are followed, many organisms and often the causative ones, will die because of the aerobic conditions.

When the focus furnishes sufficient tissue exudate or purulent discharge to make it feasible, the ideal method is to inject this infected material directly into the experimental animal. Often, however, as in the case of a devitalized tooth, the focus is not in a physical form to make this possible, or the technical difficulties of having the laboratory animals immediately available are so great as to make this method of direct injection impossible. Under such conditions, primary cultures must be made in a culture medium having a graded oxygen tension. This is accomplished by using glucose broth in which small pieces of brain tissue have been placed. "The bottom of the tube is rendered anaerobic while the top necessarily remains aerobic and the space between represents a gradient of oxygen pressure intermediate between the two extremes." (10) Cultures from this material after proper incubation may be used for injection, with the assurance that all organisms have obtained the environment most congenial to their growth. As it is important to take the utmost care in rendering this environment correct, it is equally important to take the same care in obtaining the material cultured. The surface of a tonsil will naturally be the habitat for the saprophytes and aerobic bacteria, while those that are anaerobic are only obtained from the depths of the crypts. Therefore, extreme pressure must be exerted on the tonsil to obtain the infected material in order to be sure that the bacteria from the depths, as well as those from the surface, are obtained. This is best accomplished by placing a throat mirror on the posterior aspect of the tonsil and exerting considerable pressure as the patient gags. The pharyngeal muscles, in contracting, squeeze the tonsils and express material often not suspected of being present. By this method, deep abscess pockets may break and discharge their purulent contents on the surface of the mirror which serves as the receptacle for their collection. This attention to the anaerobic properties of infective organisms cannot be too strongly emphasized, since its neglect undoubtedly accounts for many experimental failures. It is also not generally appreciated how delicate many of the most virulent organisms are, and how readily they are destroyed. Chilling the culture mediums between the time of implantation and incubation may render experimental results negative; therefore, care should be taken to incubate the cultures as soon as possible. It is probable that this extremely low vitality of the bacteria keeps many infections from producing great destruction to life, yet because of their extreme virulence under favorable circumstances, we are apt erroneously to consider such organisms as comparatively resistant.

If the methods described are followed, if lesions are produced in the experimental animal similar to those occurring in the patient from whom the material was obtained, and if from these lesions new cultures are obtained which, on second animal passage, again produce a like lesion, all the requirements

*Read before the Buffalo Academy of Medicine, November 7, 1923, Buffalo, N. Y.

Copyright, 1924, by A. R. Elliott Publishing Company.

of Koch's law are fulfilled. Rosenow and his coworkers, following these methods, have now produced the most striking results in cases of appendicitis, cholecystitis, duodenal and gastric ulcer, encephalitis, poliomyelitis, epidemic hiccough, pyelonephritis, nephrolithiasis, cystitis, iritis and other diseases. The list of diseases is so large that at first it seems to the scientist incredible and to the layman ridiculous, that so many human ills should originate from almost a single source. Yet when it is considered that the infection is through the blood and lymph, which reach every minute part of the body, the multitude of different diseases possible is evident. It has been estimated that one fourth of the human race have septic mouths at the age of twenty-five; at forty-five the number has increased to ninety per cent, and after fifty, practically all mouths are septic. When it is considered that with every bite of the jaw, bacteria around the roots of septic teeth are pumped into the circulation, the fact that we have so few, rather than so many diseases, is the marvel.

In order to study or treat such disease, the closest possible cooperation must exist between the various specialties. I am most interested in the subject as it touches my specialty, urology, and in association with Meisser of the section on dentistry, at the clinic, working in Rosenow's laboratory, I had the pleasure of demonstrating experimentally the relationship of various urological infections to focal infection. Unfortunately, such cooperation is not always obtainable, chiefly, I believe, because certain of the most important aspects of the teeth as a focus are not appreciated. The use of the röntgen ray by the dentist has become general, but the films are frequently misinterpreted, and like all aids to diagnosis, the ray is now too often regarded, not as an aid, but as the diagnosis itself. Teeth that show no changes discernible by the röntgen ray may be dead, but only a routine test of their electric sensitivity will demonstrate their lack of vitality. In other cases, the disease process may be in such a location as to be undiscernible in an examination of the films, so that while a routine full mouth röntgenogram is essential to accurate diagnosis, it should not comprise the entire examination, but should be associated with a most painstaking physical examination of each tooth. There is, I believe, no diversity of opinion concerning the advisability of removing a tooth that shows a definite apical abscess with considerable destruction of bone, but the fact seems to be overlooked that before such destruction occurs, myriads of bacteria must have existed around the root of the tooth, and that not until the process is far advanced, will sufficient destruction of bone occur to be demonstrable by the röntgen ray.

In several series of experiments, Meisser has demonstrated that bacteria from röntgenologically negative, devitalized teeth yield the same type of microorganisms as röntgenologically positive teeth, which on animal inoculation show the same selective action.

In our study of pyelonephritis, a culture obtained from a devitalized but otherwise negative tooth showed the highest elective affinity for renal tissue of any that we studied; yet often when I send patients to their home dentist for the removal of all abscessed and pulpless teeth revealed by the röntgen ray, he readily agrees to the removal of the abscessed teeth, but inasmuch as a pulpless and otherwise negative tooth may be all that remains to which can be attached a bridge and alone stands between the patient and an artificial denture, he demurs. In fact, he may show the patient the röntgenogram, point out the benefit to be derived from the removal of teeth with large periapical abscesses clearly discernible, show that the osseous tissue around the pulpless tooth appears excellent, and obtain the patient's consent to the retention of the tooth in the interest of reconstruction, thus discrediting the previous advice. He does not inform the patient that no röntgen ray machine has yet been constructed that will make a single bacterium or even several thousand bacteria cast a shadow, and that not until millions of bacteria have lived and died will there be sufficient periapical necrosis to be demonstrated röntgenographically. He probably misunderstands this aspect of focal infection. While in this type of cases error occurs through misinterpretation of the findings of the röntgen ray, in another type its neglect is responsible for error. Patients may be questioned regarding teeth, only to reply with a smile that they all have been removed for some years; the physician must then search elsewhere for a focus. Eusterman, in a study of 290 edentulous or partially edentulous mouths, found 129 roots or other evidence of residual areas of infection. Because the old methods of removing teeth did not permit the elimination of all the teeth and their associated lesions, he believes that thirty-seven per cent. of the areas to which plates are adapted will be found to harbor infection. Thus the importance of röntgen ray examination of edentulous mouths is evident, and teeth as a possible focus cannot be excluded simply because they were all pulled years before.

The granuloma resulting from periapical infection is frequently regarded as nature's method of protection, and rightly, but it is far from perfect, for sections of granuloma show that they contain countless numbers of bacteria in close proximity to the area of new bloodvessel formation, the most satisfactory association for rapid and constant systemic infection. The bloodvessels in such granuloma immediately adjacent to clumps of bacteria are frequently found to be filled with the infecting organisms.

Having called attention to the most common sources of error respecting the teeth as a source of infection, I will refer to the tonsils. At the Mayo Clinic the grading of pathological processes, or the size of organs on a basis of one to four has been found to be of considerable aid. The small tonsil, size one or two, on superficial examination appears to be harmless, while size three or four, by its size and projection into the throat, will often be recommended for removal. From the viewpoint of the otolaryngologist, this is undoubtedly sound advice. From the viewpoint of focal infection, however, the reverse is probably correct. The small tonsil is usually buried deep in the tissues, and it may be difficult or impossible to demonstrate that it harbors infection, although its buried location makes absorption from its crypts easy. The large tonsil, on the other hand, by its pendant position tends to drain into the throat, and the noxious exudates and bacteria, being swallowed, are rendered comparatively

harmless. However, this simple truism seems to be completely ignored by many. The patient is found to have a disease referable to focal infection, and on examination of the throat, is assured that the tonsils are not the focus, for they are small, nothing can be expressed and they are not inflamed. I believe that such a negative report from the viewpoint of ruling out the tonsils as a focus is worthless, and may instead indicate that they are the source. It is impossible to be sure that the tonsils are not a focus of infection by any means now at our disposal, and only a positive finding of expressible pus is of value. The larger the tonsil, the less likely it is to be a focus; the smaller the tonsil, the more likely it is to conceal deep in its substance an unsuspected pus pocket.

Another aspect of focal infection apparently generally misunderstood is the belief that benefit should result from the partial removal of foci. Physicians often say, "The experimental work appears sound and the theory is excellent, but in practice it simply doesn't work. I have removed the tonsils in many cases with no improvement in the disease." On questioning, it may be found that the tonsils were the only focus removed, the teeth being neglected, or the teeth may have been removed and the tonsils allowed to remain. In the study of focal infection in a series of eighty cases of arthritis, Brock found that forty-two patients had had possible foci removed, and that in all, demonstrable foci were still present. Twenty-five patients of the series had their tonsils removed, in twenty-two of which infected teeth were still present. It is obvious that such instances represent the disappointment of the unrelieved patient and of the physician who does not obtain the results desired from the removal of the tonsils.

Partial removal of foci will not bring even partial relief of symptoms, only complete removal can hope to accomplish this; the most painstaking care must be exercised in order that no tonsillar remnant remains. The importance of removing all tonsillar tissue is shown by the following case which was previously reported in collaboration with Meisser.

REPORT OF CASE

Case I. (A348635).—Mrs. C. E. B., aged thirty-six years, came to the clinic February 5, 1921. For a number of years she had had frequent attacks of grippe and tonsillitis, for relief of which tonsillectomy had been performed in 1916. In 1912 the round ligaments had been shortened and the appendix removed. The patient then manifested increasingly frequent urination, which persisted without relief. It was not associated with burning, but before and after micturition there was a dull ache throughout the bladder. Nocturia had increased until the patient voided from five to six times at night. On two occasions during the last two years there had been slight gross hematuria. On physical examination the bladder was found to be tender. Uranalysis revealed an occasional erythrocyte and a few pus cells. The röntgenogram of the teeth was negative. Examination of the nose and throat was at first reported negative. The patient, however, insisted that tonsillar tissue was still present, and on her urgent plea for a more careful search, a second examination revealed that the tonsils had been removed cleanly except for a slight remnant on the lower pole of the right side. On cystoscopic examination, an area of hyperemia was found on the posterior wall of the bladder near the dome, surrounded by edema. A diagnosis of submucous ulcer of the bladder was made. On February 15th, the involved portion of the bladder was resected. The pathologist reported a submucous ulcer seven mm. in diameter.

Cultures were made from the remnant of the right tonsil before its removal, and many green producing streptococci and staphylococci were found. With these cultures two animals were injected. One died soon after the injection. In the other innumerable small hemorrhagic lesions developed in the bladder; there was no evidence of lesions in other organs. The remnant of the right tonsil was removed and cultures made from the emulsion. Again the green producing streptococcus was the predominating organism. Three rabbits were injected with these cultures, two of which had innumerable hemorrhagic lesions, varying from 0.09 to 1.5 mm. in size. The third rabbit had a few hemorrhagic lesions in the bladder, and pronounced lesions in the medulla of the kidney. Such an area of infection was overlooked in our routine examination, and yet if it had not been ultimately discovered, little permanent benefit would have resulted from the resection of the ulcer bearing portion of the bladder. The disease must of necessity have recurred if the focus had persisted.

Thus does the subject of focal infection enter the field of preventive medicine although its importance is hardly recognized. Yet the physician or surgeon has not done his duty who has merely relieved the patient temporarily of a pathological lesion, the cause of which the patient is allowed to retain. Eusterman (4), in a recent paper on recurrent ulcers of the stomach and duodenum, says, "the theory that infection is the cause of ulcer is admittedly the only tenable one at this stage of medical progress," and "the radical removal of all possible foci has repeatedly caused subsidence of gastrointestinal disturbances, and evidence of increased healing of otherwise refractory ulcer." In a series of thirty-two patients with recurring gastric or duodenal ulcer studied by him, twenty-nine harbored extensive foci, especially in the teeth and tonsils, or both, a fact which he considers more than coincidental. He cites a typical case in which the patient had had posterior gastrojejunostomy for duodenal ulcer and appendectomy in June, 1921, and had remained well for one and a half years. His teeth and tonsils were septic and although treatment was advised, it was not carried out. Symptoms recurred, and röntgenograms revealed evidence of ulcer on the lesser curvature, also partial lack of patency of the gastroenterostomy stroma signifying early gastrojejunal ulcer. The tonsils, from which pus was expressed, and four pulpless teeth with well marked area of rarefaction, were removed. Ulcers were produced in thirty-seven of forty-four animals injected with cultures from these foci. Coincidental with the removal of the foci of infection the patient recovered and has remained well. Prophylaxis in the form of the removal of all foci must evidently be combined with surgery in such cases if results are to be obtained

that will bring credit rather than disrepute to the profession.

In the practice of urology, equally striking results have been achieved experimentally, and many aspects of focal infection in relation to urinary infections clarified. Infection in any part of the urinary tract, as a rule, is characterized by a predominance of colon bacilli, although their mode of entry remains obscure. Their predominance is, I believe, responsible for the delay in accepting the idea that focal infections can cause disease of the urinary system.

Le Fur, in 1901, had attempted to produce vesical ulceration by the intravenous injection of various bacteria into laboratory animals. The results were so unsatisfactory that he abandoned this technic, and injected the organisms either directly into the bladder or into the perivesical space. He used ten strains of bacteria, including the streptococcus, pneumococcus and colon bacillus. After injecting the colon bacillus he recovered the organism in pure culture, but after injecting the other bacteria, the original strain was invariably found to have become associated with colon bacilli, although none had been injected. In three cases, although other bacteria had been injected, colon bacilli only were recovered. These results brought out two important points, first, that the intravenous injection of colon bacilli seldom causes the production of localized lesions, and second and more important, that after the injection of other bacteria, which results in lesions of the urinary tract, the colon bacillus is often found as a secondary invader. These facts would explain why dental and tonsillar sepsis, which seldom is associated with colon bacilli, and which is so commonly found in patients suffering with pyelonephritis, might produce infection of the urinary tract in which the outstanding organism is the colon bacillus.

A group of twelve patients at the clinic suffering with pyelonephritis were selected, who had a history of fairly recent tonsillar or dental sepsis, and in whom such foci were considered to be still active. Eighty-two animals were used; fifty-three were injected with the primary culture of tooth or tonsil, eleven with bacteria obtained from the urinary tract of the animals injected with the primary culture, six with bacteria from this second animal passage, two with cultures from the blood of patients, and ten with cultures from the urine of patients. Lesions were found in the kidneys of sixty-three of the animals. The record of one patient in the series is so interesting as to warrant reporting.

REPORT OF CASE

Case II. (A344376).—Mrs. M. H., aged forty-five years, came to the clinic complaining of bladder trouble. Three weeks before, at the onset of her menstrual period, she had noticed slight irritation at the neck of the bladder and burning at the end of urination. Two or three days before she had been up all night with a daughter suffering with tonsillitis. She became chilled and had a sore throat for the next few days. The bladder trouble grew gradually worse, and the local physician attended her for the next two weeks, during which time her temperature ranged from 99° to 104.5°; the night before she came to the clinic it was 104.5°. She complained very little of pain, except that occurring at the end of urination; she felt a slight soreness around the crest of the right ilium. Cystoscopic examination had been made two days before, and inflammation was found around the right ureteral orifice. Colon bacilli were recovered from the urine. A diagnosis was made of mild cystitis.

Examination revealed slight tenderness in the right abdomen and over the crest of the right ilium. The temperature was 101°. Röntgenograms revealed evidence of periapical infection in four teeth. One was devitalized, but the röntgenogram was negative; the pulp was exposed in two teeth. From the tonsils, which were not greatly enlarged, fluid pus was expressed. An occasional red blood cell and a large amount of pus were found in the urine. Stained specimens were negative for tuberculosis bacilli. Röntgenograms of the urinary tract were negative. Two cystoscopic examinations, made before the suspected foci were removed, proved negative, but the urine recovered from the kidneys contained pus and gave a pure culture of gram negative bacilli. Three rabbits were injected with a culture of these bacilli, and in none could evidence of lesions be found. The day after the second cystoscopic examination, two of the teeth with apical abscesses were removed, and cultures were made on blood agar plates, and in glucose brain broth. In both, green producing streptococci were isolated on the blood agar plates. A few colonies of staphylococci were also present. Three rabbits were injected; all had lesions of the kidney and one had multiple minute hemorrhages (?) in the right ureter near the pelvis of the kidney. Streptococci in pure culture were removed from these lesions. The patient experienced no immediate reaction, such as often occurs following the extraction of infected teeth, although for the next few days her temperature reached 101°. Six days later three other teeth were removed, including one which did not show evidence of apical infection in the röntgenogram, but which had been devitalized and the root canal filled. All gave pure cultures of green producing streptococci. These were injected into three rabbits, and resulted in lesions of the kidney in two, one of which had been injected with bacteria from the devitalized, but otherwise negative tooth. The third rabbit did not have lesions. The day following the removal of these teeth, the patient had a severe chill, and her temperature reached 106°; profuse sweating and falling temperature followed. During this reaction a blood culture was taken and large numbers of a green producing streptococci were recovered. Two rabbits were injected intravenously with samples from this culture. Lesions in the kidneys developed in both, and cultures made from these lesions yielded green producing streptococci, while cultures from the gallbladder, blood, spleen, liver and so forth, were negative. The febrile attack was so acute and severe that doubt was expressed with regard to its renal origin. The possibility of its being a respiratory infection was suggested, although there were no pulmonary symptoms. In order to clear this point, cultures were injected directly into the trachea of five guineapigs. At necropsy no pulmonary lesions were found, but in one guineapig the kidneys and ureter were markedly involved.

Urine obtained from the bladder the day of the chill, the following day, and the fourth day, con-

tained only colon bacilli. On the fifth day, however, when the patient had recovered sufficiently to permit cystoscopy, the urine obtained from the kidney and bladder contained occasional streptococci, but far greater numbers of colon bacilli. Samples of the mixed cultures were injected into five rabbits; and in three lesions of the kidneys developed. Streptococci and colon bacilli were recovered from the lesions in two rabbits; the other three had lesions in the intestines.

In order to study the relative ability of the two organisms to grow in urine, a twenty-four hour sample of the patient's urine was autoclaved on three occasions, and, after being proved sterile, samples were inoculated and incubated with colon bacilli, with streptococci, and with both. It was found that while the colon bacilli multiplied readily, the streptococci had no such ability, and only a few more than were planted could be recovered. This probably explains the usual absence of the etiological organism in the urine of patients with pyelonephritis. Occasionally, as in the case reported by Kretschmer, secondary colon bacillus infection does not occur, and streptococci are obtained in pure culture.

Eighteen days after the second extractions, the patient's remaining infected teeth were removed without incident. Pure cultures of streptococci were recovered. Four animals were injected; in two lesions of the kidney developed, one very pronounced; one had lesions of the joints, the uninfected organs being sterile. During the intervals between the extraction of her teeth the patient was cystoscoped four times, and at each examination pus cells were found in the urine from the kidney, and cultures therefrom contained colon bacilli; a few streptococci were also found after the second extraction. After all of the infected teeth had been removed, six cystoscopic examinations were made. The specimens of urine from the kidneys were free from pus, and on culture a gram negative bacillus was the only organism found. Cultures made at each successive cystoscopic examination yielded fewer organisms; the last one from the urine from the right kidney, which was taken at the time of the patient's dismissal, one month after the last of the septic teeth had been removed, contained only fifteen colonies on a blood agar plate; cultures from the left kidney were negative.

During the time pus was found in the urine from the kidneys, the pelvis was lavaged with a one per cent. solution of silver nitrate, but after the disappearance of the pus following the extraction of the last teeth, only boric acid was employed. A specimen of the patient's voided urine was brought to the clinic one month after her dismissal. The findings were negative except for three pus cells to the microscopic field. Her physician said that she was free from symptoms, and had had no fever.

The experiments in this case demonstrate that infections of the urinary tract may often be the result of foci of infection harboring streptococci which have a selective affinity for the urinary tract, and that the colon bacillus which is commonly found and generally believed to be the cause, is of secondary importance. The case also illustrates a situation that is common during the eradication of foci of infection, and which is often wrongly interpreted. I refer to the extreme reaction suffered by the patient following the second extraction of teeth. I believe the reaction experienced by a patient following the removal of a chronic focus may be regarded as an indication that the offending focus has been found and should, therefore, be regarded favorably. Many, however, on finding that the patient's symptoms grow worse immediately after removal of foci, consider it as derogatory evidence in respect to this type of treatment. Stokes has called attention to the reduction in renal irritability that results from the removal of foci of infection in patients being treated for syphilis. By first removing all foci he has been able to increase, very appreciably, the amounts of mercury and arsphenamine administered.

That the formation of renal stones may be the result of bacterial action is a venerable hypothesis, and from the first evidence of the specificity of bacteria for the urinary tract, the hope of their experimental production by this means was entertained. However, although many animals were injected with bacteria from patients with nephrolithiasis under the same conditions that the animals were injected in the group of previous experiments, no positive results were obtained. It happened that, during the experiments on pyelonephritis, an attempt was made to produce an immune serum by repeated intravenous injections into a sheep of various cultures of dead bacteria obtained from patients with pyelonephritis. At necropsy the sheep's kidney was found to contain multiple calculi. To inject cultures intravenously over a long period is tedious, and a chronic focus is only partly simulated. Meisser, therefore, conceived the idea of producing a chronic focus by devitalizing a dog's tooth, and filling the root canals with bacteria obtained from the teeth and tonsils or urine of patients suffering with nephrolithiasis. After several months, röntgenograms were made, and in the renal areas of several of the dogs there were shadows, although they had not been present in previous röntgenograms. In the kidneys of many of the dogs were stones too small to produce shadows in the röntgenograms. On microscopic examination of the tissue of the medulla of these kidneys, many salt crystals and bacteria were found.

I believe the foregoing findings justify the somewhat dogmatic clinical teaching, that all patients who have a disease referable to a focus of infection shall be advised to have all such foci removed, thus removing the most formidable opposition to the general adoption of such a practice, for, as pointed out, partial removal of foci does not give partial relief of symptoms, and yet is more general than complete eradication. Also, septic teeth and tonsils are removed too often, with the assurance of benefit to the patient, after the heart has begun to beat irregularly, after albumin or pus has appeared in the urine, or after the joint has become deformed. Strange as it may seem, the idea that normal function can be restored to an irreparably damaged kidney, a deformed joint or leaking heart valve, by removing a focus that initiated the disease years before, is apparently the most common misapprehension regarding focal infection. Emphasis should be placed on the fact that the diseased tonsil or

abscessed tooth should be removed because they are diseased, and not because improvement may result to some chronic disease elsewhere in the body. When this is realized, and when all devitalized teeth and infected tonsils are immediately removed because of the disease demonstrable, then will the inestimable results of early eradication of foci of infection be achieved.

Microgastria*

RALPH L. HOYT, M.D.,
Baltimore

The subject of microgastria, or congenitally small stomach, is one which has received practically no consideration in medical literature. Strümpell (1) says that "whether congenitally small stomach, giving rise to pathological changes or causing symptoms, exists, is not yet known." Kemp (2) mentions the term simply to pass it by. Numerous other writers have written of the capacity of the stomach but an exhaustive search of the literature fails to reveal a single instance in which a congenitally small stomach has been assigned as the cause of symptoms or death in the infant. We often read of cases in which abnormal smallness or absence of any vital organ is given as the cause of illness or death of the individual, and so it seems fair to assume that abnormal smallness of the stomach could readily give rise to symptoms which would cause illness, and, if not correctible by any means at our command would result in death to the individual by starvation or otherwise.

The part taken by the stomach in digestion in young infants is comparatively unimportant, aside from the coagulation of the milk by the rennin. It is doubtful if any other action takes place before the milk reaches the intestines, and indeed a large part of the milk reaches the intestines without even the coagulation having been effected. It would seem, therefore, that in the early weeks of life the function of the stomach might be considered to be that of a tube or channel for the conveyance of the food to the duodenum, where the active digestive process starts.

As the infant grows older, however, the part played by the stomach becomes much more important, as evidenced by the longer time the food remains in the stomach. It is at this time of life that we would expect symptoms to appear, in the case of abnormality in the size of the organ.

As the acidification of the gastric juice begins very soon after the ingestion of food and steadily increases until sufficient hydrochloric acid is present to give an acid reaction, the inference can be readily drawn that, in a stomach of subnormal capacity, the outflow from the glandular elements is poured out into the stomach, and finding little or no milk to act upon there results an enormous hyperacidity of the stomach. This produces symptoms which in the infant usually manifest themselves by persistent vomiting. As continued oversecretion or overactivity of any organ will eventually result in proliferation of the tissues composing it, one would expect to find in a small stomach an enormous thickening of the walls. Furthermore, because of the overactivity of the glands in the submucosa one would expect to find this coat of the stomach thickened and the gland elements much increased in size and number.

It would thus seem that in a congenitally small stomach there would be practically no symptoms for the first few months of life. However, as the infant becomes older and stomach digestion assumes its proper rôle in the economy, one would expect the child to be undernourished, because of the small amount of food it obtained for digestion. As explained above, there would then develop persistent vomiting as a result of the hyperacidity due to the large amount of acid secreted in proportion to the small amount of digestion taking place in the abnormally small stomach. This condition would inevitably cause the death of the infant from starvation as not only would the amount of food taken into the stomach be abnormally small, but even this small amount would in all probability be expelled by the persistent vomiting. The following case illustrates rather strikingly the process described:

CASE.—Baby H., female, aged thirty-six weeks, weight thirteen pounds, was admitted to the South

*From the Department of Pediatrics of the South Baltimore General Hospital.

Baltimore General Hospital, August 24, 1922, from the outpatient department, with a history of persistent vomiting. The family history was negative and the past history recited the facts of a normally born and breast fed infant. The history was negative for any illnesses until July 1st, when the mother brought her to the dispensary for treatment for attacks of vomiting. The physical examination was negative, with the exception of an elevation of temperature to 103° on admission. The temperature continued to run an irregular course (99° to 102°) until alkalinization of the urine with potassium citrate and forced water drinking was obtained, when it became normal. It remained normal until the fever of inanition started in the latter weeks of life.

Laboratory findings were negative, with the exception of the urine, which was strongly acid and contained albumin on chemical examination. It showed from five to seven pus cells to the field on microscopic examination. A Wassermann test was not done on the blood. Otherwise the laboratory examination was complete and included examination of the blood, cerebrospinal fluid and urine. The Wassermann test of the cerebrospinal fluid was negative.

An x ray examination was made on two occasions. The first examination was both fluoroscopic and plate. Under the fluoroscope the barium, which was introduced through a soft rubber catheter with a syringe, was seen filling out the stomach and could be forced through the pyloric opening by the operator's hand. The plate at this time was unsatisfactory as the baby vomited most of the barium between the time of fluoroscopic examination and taking the plate. The second examination, made about one week after the first, was confined to introducing barium and taking the plate immediately (Fig. 1).

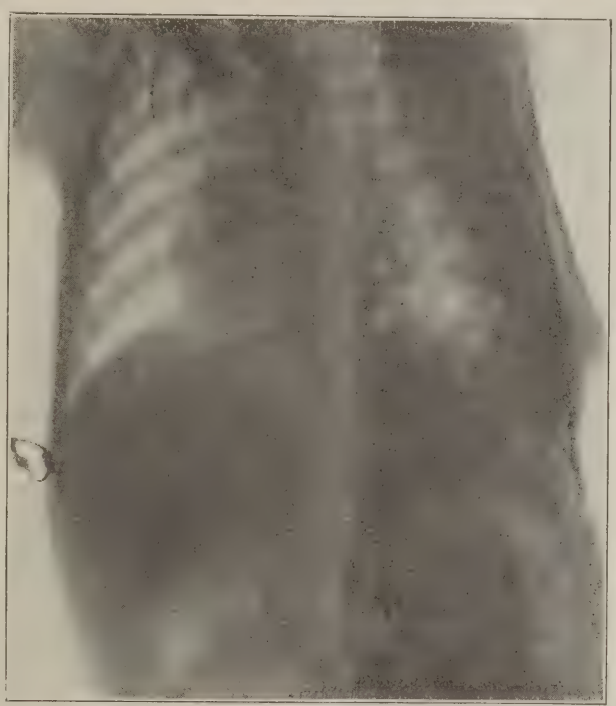

Fig. 1.—Röntgenogram taken immediately after the introduction of barium, showing congenitally small stomach.

A diagnosis of pyelitis was made on the urinary findings and temperature, the vomiting being attributed to the urinary condition. The vomiting continued, however, after the subsidence of all urinary symptoms, with short remissions, until death occurred October 18, 1922.

The character of the vomiting was not noteworthy, except that at first it was quite forcible, resembling projectile vomiting, but as the patient gradually became weaker it resembled an overflow more than an act of vomiting.

Food combinations of various mixtures were used, among them being milk, water and cane sugar; milk water and dextromaltose; protein milk; oatmeal and arrowroot gruel, etc. The heavier mixtures would be retained for a slightly longer period than the others, but usually the vomiting occurred immediately on the ingestion of food. The time of feedings and the quantities were changed several times. At one time an endeavor would be made to give large quantities of the mixtures from four to five ounces at four to five hour intervals, and when no benefit resulted shorter intervals between feedings with smaller quantities were substituted. When feeding the larger quantities the nurse reported that the baby would start vomiting in the middle of the feeding, when approximately two ounces had been ingested. Later in the illness the baby was fed with a medicine dropper at intervals of not over a half hour. The appetite at all times after the subsidence of the fever was ravenous and the baby always appeared to be hungry. The bowels were obstinately constipated throughout the entire course of the disease until the last week of life, when the movements became normal, both in character and frequency.

Deglutition seemed to be embarrassed more or less from the beginning. The baby showed an aversion to taking the nipple and would roll it around in the mouth instead of taking hold and sucking. A rather persistent stomatitis was present on admission and this, together with the fact that the baby had been breast fed and had to learn how to use the rubber nipple, was held to be the cause of the difficulty. When fed with a medicine dropper there was no difficulty in swallowing. Examination of the nose and throat was negative for any interference with the act of swallowing. Various medicaments were used, among them being tincture of belladonna by mouth and later atropine sulphate hypodermically. No response to any method of treatment was noted.

Autopsy findings were negative, with the exception of the small stomach. On removal the stomach was ligated at both ends and water was introduced through the wall with an ordinary syringe. The capacity (without pressure) was thirty c.c. Under pressure fifty c.c. could be forced into the organ, but this represented the extreme capacity. The normal capacity at this age (forty-four weeks) varies according to different authors, but can be given as approximately three hundred c.c. The abnormally small capacity of this stomach was therefore a matter of great interest.

Dr. W. G. MacCallum, professor of pathology at Johns Hopkins University, kindly consented to make sections from the stomach and I am indebted to him

for the following report on his findings. "On section the wall was found to be greatly thickened, due partly to contraction of the muscle, but also to an increased thickness of the submucosa. The mucosa itself was quite extensively altered and showed a curious condition in that many of the glands were converted into small cysts and the interglandular substance was infiltrated with cells and much scarred."

CONCLUSIONS

It can be assumed that congenital smallness of the stomach can readily be the cause of symptoms and, if sufficiently pronounced, have a fatal termination. In all cases of persistent vomiting of unknown origin and accompanied by great inanition, the possibility of congenitally small stomach should be borne in mind as a causative factor.

The röntgenological findings in the case reported were given little weight, as on account of the extreme smallness of the stomach shadow it was assumed that the technic was at fault. The autopsy, however, revealed that the operator labored better than he knew as the plate was found to be an exact replica of the organ as removed.

In all cases of persistent vomiting the stomach should be injected with barium and a careful röntgenological study made before eliminating microgastria as a cause of the condition.

The Prophylaxis and Serum Therapy of Typhus Fever

SOLOMON KAGAN, M.D.,

Boston

Formerly Head of the Zemstro Hospital in Crimea, Visiting Physician to the Konstan Red Cross Hospital and Government Physician in Typhus Districts of Rostov

The absence of any specific treatment for typhus fever, and the high mortality in the epidemics, brought about the compelling necessity of the search for a prophylactic and curative serum. Many sera have been tried out and, although their effect was never very striking, it is possible to form some opinion of their value as a prophylactic, curative or abortive factor. The results were never uniform, in fact, very frequently they differed substantially.

As to the use of the serum and blood of typhus patients for purposes of prophylaxis, they are of no value. Many vaccines were proposed. 1, Nicolle's method—the vaccine of serum of typhus patients; 2, Hamdi's method—the vaccine of citrated blood of typhus patients heated to 60° C.; 3, Neukirch's method—the vaccine of leucocytes of the blood of typhus patients; 4, Rochazim's method—the vaccine of emulsion of typhus lice; 5, Aristovsky's method—the vaccine of a culture of Bacillus proteus X_{19}. Nicolle first employed in thirty-eight cases the serum from the blood of typhus patients on the eighth to ninth day of their illness or from animals on the second to third day of their infection. The injections were given at intervals of seven to eight days, two injections being the rule, but the results were doubtful. Out of thirty-eight patients coming from centres where typhus was prevalent, and who received prophylactic doses of serum twice, none were affected with typhus, but Nicolle is uncertain whether to ascribe their escape to the serum or possibly to the strict measures of disinfection to which they were subjected (1). Others gave three injections of mixed sterile serum of several typhus patients (pool serum), heated to 58° C., to which was added one fourth of one per cent. carbolic acid.

First, one c. c. was injected, followed in five to seven days by another injection of two c. c. and seven days later a third of three c. c. was given. Out of 129 cases thus immunized, ten persons contracted the disease, two of whom died (Barikin Rosnatovsky and Kagan). Some have given the serum in the form of citrated blood of typhus patients (eighteen c. c. blood and two c. c. of two per cent. solution of sodium citrate). I. P. Rosnatovsky and the writer employed it thrice in the same doses and order as that given above. Out of 232 patients to whom this serum was given as a prophylactic twenty-two were afflicted with typhus and two died (2). The citrated blood of a typhus patient was also used by S. I. Slatogoroff. He compiled reports of 2,914 such cases. The results were not satisfactory out of that number, 117 came down with typhus. He asserts that it is more rational to inject only once, using seven c. c. as the dose.

Ermiloff applied the same serum to 411 persons of whom thirty-four came down with this malady. Mizkevits used the serum in fifty-nine cases, in which, nevertheless, fourteen patients contracted the disease. They conducted experiments to immunize the human being against typhus by means of cultures of different proposed etiological virus of typhus (Plotz and Rabinovits microorganisms and the proteus X_{19}) also gave negative results (3).

Concerning serum therapy it is still being investigated. Although the experiments have not been extensive, it is possible to come to some conclusion concerning its value. The administration of normal horse serum is not followed by any improvement but the serum of convalescent typhus patients apparently is of some curative value.

Rubitschek obtained good results using normal horse serum. But this is disproved by Barikin, who experimented with normal horse serum, antidiphtheritic, and antistreptococcus sera in twenty-eight cases. The serum was injected from the fourth to the eighth day of the illness in doses of thirty to sixty c. c. for the course of treatment. In all these cases he did not observe any improvement which

ould be attributed to the serum; the temperature, ulse, respiration, general status and nervous symptoms were the same as among those treated without is serum; the complications were not diminished, ne duration of fever not shortened. True, among hose treated with this serum only one death is recorded, i. e., 3.5 per cent., while among those not o treated, the mortality during the same time in this ospital was 14.5 per cent., but this decreased mortality is accounted for by difference in the ages of he patients, for those using the serum were of the verage age of twenty-five, while the others averged thirty-one.

TABLE I

MORTALITY, AGE AND MORBIDITY UNDER TREATMENT BY NORMAL HORSE SERUM.

Twenty-eight Cases Treated	*Percentage of Mortality*	*Age*	*Morbidity*
y normal horse serum	3.5	25 years	No improvement.
Io serum therapy	14.5	31 "	"

Other experimenters used the serum of convalesent typhus patients (three to twelve days after the all of the temperature). About this serum there re also different contrasting statistics. Legrain, 'enaud, Slatogoroff and Ivashinzeff observed from mploying the serum a considerable improvement, ometimes even an aborting of the disease. Marinovsky used the serum of convalescents between he sixth and ninth days after the fall of the temerature, allowed it to precipitate and then mixed ith it an even amount of normal saline solution. his he heated for half an hour in a water bath t a temperature of 56° to 58° C. This serum was aken from several patients, mixed together, and mployed only in the most severe cases of typhus n the first day of the illness. Usually, he injected wenty c. c. of this solution hypodermically; in the ext one or two days he repeated the injection. He eported thirty-eight cases where he observed some nprovement, and of those thirty-eight patients seven ied. Such a high percentage of mortality is due o the bad condition of the patients. This serum as little influence upon the temperature. In cases f meningitis he saw improvement; headache, inomnia, and delirium disappeared, convulsion topped, the contractures became weaker. In rare ases with a marked myocarditis and intermittent ulse, after the injection of serum the pulse beame regular. In one case of severe perichondritis ith a complete aphonia, after each injection the oice appeared again. He asserts that this serum has certain curative value (4). But this fact is not onfirmed by other authorities. Kolpitin used the ame serum in doses of from three to five c. c. for hildren, and did not notice any effect (5). Barikin ompiled reports of fourteen typhus fever cases in hich sometimes a temporary fall of the temperature 1° to 1.5° C.) was caused by the injection of the erum of convalescents; but this effect followed lso the injection of normal horse serum which has o curative value. According to Barikin's records he average duration of fever among those treated y this serum was 14.2 days, their average age was wenty-four years, and there was no death, but in ther respects there was no improvement.

TABLE II.

MORTALITY, AGE, DURATION OF FEVER AND MORBIDITY UNDER TREATMENT BY SERUM OF CONVALESCENTS.

Fourteen Cases Treated	*Percentage of Mortality*	*Age*	*Duration of Fever*	*Morbidity*
With serum of convalescents	0	24 years	14.2 days	No improvement.
No serum therapy	14.5	31 years	15 days	"

Barikin suggests that this serum of convalescents cannot claim to be a specific remedy for typhus; the absence of deaths he attributed to the youth of those patients (6). Doubtful results about the value of this serum were observed also by Nicolle, Conseil, Neukirch and Zlocisty. Finally, Boldiroff and Kastanian (Rostov) deny the value of this serum altogether.

Concerning the serum of a horse immunized against typhus fever, there were reported beneficial results by Nicolle, Potel, Poirson, Pazevitz, Tridoin and Barikin. Pazevitz used for immunization of the horse the blood of typhus patients of human beings. But Nicolle immunized the horses by means of a guineapig infected with typhus; Barikin also recommended the use of serum of the guineapig, because the blood of the human being gives cystolysis and hemolysis serum for the tissue, blood and organs of other persons. He immunized two horses as follows: The blood of the guineapig infected with typhus was taken the first day of the fever; from this blood was taken a specimen for culture to be sure that this blood was sterile; then the organ was pressed, mixed with 0.8 gm. of sodium chloride to each 100 c. c., filtered through gauze for the purpose of making it free from coarse pieces and immediately was employed for immunization. The injections of the antigen were made intramuscularly in ascending doses from one c. c. to one hundred c. c. At each injection the horse responded by fever. The injections lasted seven months, then twelve days after the fall of the temperature of the horse, its blood was taken and serum prepared; the serum was heated to 45° C. two days in succession for half an hour each day, to it added one half of one per cent. chloroform and divided in ampoules of ten c. c. each. Barikin observed thirty cases treated by this serum in the medical clinic of Don University.

Injections were made hypodermically, beginning on the fourth to the eighth day of the illness in doses of ten to sixty c. c. at once. The results: the status praesens often became better, the nervous symptoms weaker, pulse and respiration, apparently better, temperature fell by crisis or lysis, but the disease was not aborted; the average duration of the fever was 14.6 days, while among those not treated with the serum the duration was 16.8 days. Out of thirty patients treated with this serum two died, one in the fastigium of the disease; the second was forty-eight years of age with marked general tuberculosis; this case cannot be counted. Hence, the percentage of mortality among them is 3.3 per cent., while among those treated without the serum the mortality in the same hospital and same time was as high as 12.5 per cent. Moreover, the outlook of the latter was better than for the first group; the average of the second group was twenty-four years, of the first, twenty-eight and a half.

TABLE III.

MORTALITY, DURATION OF FEVER, AGE AND MORBIDITY UNDER TREATMENT WITH SERUM IMMUNIZED HORSES.

Thirty Cases Treated	*Percentage of Mortality*	*Duration of Fever*	*Age*	*Morbidity*
With serum of immunized horses	3.3	14.6 days	28.5 years	Improvement.
No serum therapy	12.5	16.8 days	24 years	"

CONCLUSION

The use of different serums for purposes of prophylaxis has no justification in theory nor has been proved of value in practice. Betore the virus is definitely found and isolated, appropriate sera for prophylaxis must of necessity be difficult. But therapeutically, however, typhus serum, especially the serum of immunized horses, is of distinct service, since its employment in addition to other established treatment has materially lessened the morbidity as well the mortality of typhus fever.

Anorectal Operations Under Local Anesthesia*

JOSEPH F. SAPHIR, M.D.,

New York

Consulting Proctologist, Manhattan State Hospital; Chief of Rectal Department, Stuyvesant Polyclinic

In 1920, Dr. Louis J. Hirschman, of Detroit, read a paper on the standardization of operations for internal hemorrhoids, in which he stated that: "In our own specialty it seems that the time has arrived for our consideration of the standardization of certain operative procedures directed to the relief of some of the more common proctological affections." It seems to me that not enough serious thought or consideration has been given to Dr. Hirschman's plea, and it is the object of this paper to renew this plea for standardization and to elicit further discussion with especial reference to operations under local anesthesia. The entire medical profession looks up to the American Proctological Society, and in its annual transactions expects to find the last word in things proctological. By neglecting to place ourselves on record as accepting certain operative procedures and condemning others, we fail in our endeavor to hold that authoritative position in proctology that we should hold in the medical body.

Local anesthesia in rectal operations has been developed and perfected to a stage where we can safely say that in the hands of the Fellows of the American Proctological Society, from sixty to ninety-five per cent. of all anorectal conditions requiring operation can be performed without the use of a general anesthetic. Some of us are more partial to its use than others. For the past thirty years, the profession has been interested in local anesthesia; various strengths of numerous solutions have been used, ranging from six per cent. cocaine or betaeucaine solution down to one eighth or one tenth per cent. with relatively good results. Even sterile water has been used with some success.

A local anesthetic to be valuable must not of itself be a cause of pain, either before its action is established or after its action has ceased. None of the drugs are used pure, but all should be dissolved in fluids isotonic with the juices that bathe the body cells, such as a 0.9 per cent. solution of common salt.

Cocaine has its disadvantages even when used in one tenth per cent. strength, in the rectum, and is followed by severe excruciating pain almost immediately after operation, and also toxic symptoms. Betaëucaine has almost the same action as cocaine, and produces the same symptoms as a protoplasmic poison, but when used in larger doses it is less powerful as a local anesthetic, does not diffuse as well, and is more irritating, but can be sterilized by boiling. Stovaine is too irritating for infiltration about the anus, but may be used for spinal anesthesia.

Alypin is soluble in watery solutions, is less active, but more irritating than cocaine and produces the same toxic symptoms. Novocaine is feebly poisonous, and up to a ten per cent. solution is nonirritating, may be sterilized and resterilized without any marked effect upon its anesthetic properties. Quinine and urea hydrochloride, the use of which I have described in the NEW YORK MEDICAL JOURNAL, in 1916, 1917, 1918, and 1919, I have discarded, on account of the almost immediate production of fibrin into the injected tissues, somewhat distorting the geography of the operative field, the frequent delay in healing, and sloughing of the tissues which sometimes takes place due to the delayed absorption of the fibrin. Its principal quality of value is that the anesthesia will last three to ten days.

The physiological action of all the drugs mentioned above, with the exception of novocaine and cocaine, is incompatible with adrenalin. The only drug relatively nonirritating, nontoxic, at the time of use and after operation, soluble in water, capable of being sterilized with heat, and nonantagonistic to adrenalin, is novocaine.

In 1917, an article of mine (1) was published on

*Presented at the annual meeting of the American Proctological Society, held in Los Angeles, Cal., June, 1923.

Quinine Urea Hydrochloride, the Ideal Local Anesthetic, where in a series of over two thousand cases, I had successfully operated, using quinine and urea for local anesthesia, and advised its use as representing seventy to seventy-five per cent. of all cases requiring surgical treatment.

About a year ago, Dr. Zobel, of San Francisco, while on a visit to New York, demonstrated to me the use of novocaine with adrenalin, and for the past year I have limited myself to the use of novocaine, and have found it to be the most practical, and for rectal operations should be the anesthetic of choice, on account of its slight toxicity, its permitting the use of larger doses without danger, and the carrying out of a complete operation performed with difficulty or not at all with cocaine. It has marked anesthetic power and is neither irritating nor has it any dilating effects upon the bloodvessels. The disadvantage of novocaine is its short duration as a local anesthetic, lasting only about twenty minutes, but the addition of three minims of adrenalin to the ounce causes the anesthesia to become more pronounced and of longer duration without adding to the toxicity of the drug.

The nerves supplying the anus and rectum are: The pudic nerves supplying parts of the anus; the pelvic branches of the posterior cutaneous femoris, which pass through the inguinal canal and supply the anal region and perineum, and the nerves originating from the coccygeal plexus supply the anal region. The sympathetic ganglion has no part in the sensory innervation. Bilateral blocking of the trunk of the pudic nerve will not be sufficient to produce anesthesia of the anus, nor will the filling of the ischiorectal fossæ with one half per cent. novocaine solution be sufficient, although this will cause blocking of the branches of the pudic and posterior cutaneous femoris nerves supplying the anus.

Sacral and spinal anesthesia, I shall not touch upon. I do not use these forms of anesthesia, but in the hands of competent men, they produce excellent relaxation of the sphincter muscle, and anesthesia of the anal region.

The mucosa of the stomach and intestinal tract, we all know are insensitive. Even in the most sensitive persons, absence of sensation begins in the esophagus and extends to the rectum, painful sensation again appearing in this part and becoming more pronounced in the anal portion at the mucocutaneous junction, where the rectum ends and the anus begins. Absolute lack of sensation of the mucous membrane of the colon may be demonstrated in any artificial anus, as in a colostomy or ileostomy, or a sigmoid when fixed to the anal or sacral region.

For the production of local anesthesia in rectal operations, four points of entrance about the anal region originally were used, two or three finger breadths distant from the anal orifice; the solution was injected perpendicularly, at the lateral points, parallel to the wall of the rectum into the sphincter and levator ani muscles, then into the subcutaneous tissues using about five to six ounces of solution. For many years the direct method of infiltration of various solutions into the tissues to be operated upon or to be removed was practised.

During the past year, following the method used by Dr. Zobel (although he does not lay claim to originality), I have found in a series of over five hundred cases that the best and most reliable method of producing local anesthesia for operations upon the anus and rectum lies in circuminjecting the anus. For this purpose I employ an isotonic solution of one half per cent. novocaine, with the addition of three minims of adrenalin (1-1000) to the ounce. Greater concentration is not necessary. Beginning at a point about one half inch posterior to the anal margin, with the aid of a fine needle about two or two and one half inches long provided with a sharp point for easy entrance, inject under the skin about the anus, first to the right and then to the left without removing the needle, so that the tissues circumscribing the anus receive the benefit of about four to six drams and very seldom more than one ounce of the solution. After massaging the injected parts for one or two minutes, to allow for the proper dissemination and absorption of the anesthetic fluid, a most complete relaxation of the sphincter muscles is obtained, even in the presence of an acutely painful ulcer or fissure, or a greatly hypertrophied muscle. The anus becomes patulous, completely relaxed, and brings into view any and all rectal disease that may be discovered when the patient is under the influence of a general anesthetic. There is absolutely no need for stretching the sphincter or dilating the anus, which frequently means the tearing of some of the muscular fibres of the sphincter. A fine needle should be used and the solution should be injected slowly. The needle should not be permitted to reach or perforate the lumen of a fistulous tract, ulcer, or other lesion, or puncture the skin or mucous membrane. This would permit the escape of the injected fluid and would interfere with the success of the operation as far as the anesthesia is concerned. Absence of pressure in any form of infiltration anesthesia prevents thorough anesthesia, and is a basic principle in local anesthesia.

Patients can be operated upon, under local anesthesia, at home, in the clinic, at the office, or in the hospital. They do not require excessive preoperative preparation; they are not restricted as far as food or drink is concerned, but are warned against taking cathartics or enemata immediately before operation. When the patient is sent to the hospital he is usually sent in at 7 a.m. after having had his breakfast, and is operated upon at 8 or 9 a. m.; his regular meals are not interfered with, he is not tortured with the insertion of any rubber tubes or whistle, nor is it necessary to tie up his bowels with bismuth and opium or any other opiate for five to seven days. Instead of this, these patients have their dressings changed the day after operation, when they receive an oil enema and are encouraged to move their bowels the same day, and usually leave the hospital at the end of three days.

During the past year, in a series of over five hundred cases, I have used the circumscribed injection method of local anesthesia with the aid of novocaine one half per cent. and adrenalin (1-1000) three minims to the ounce. This represented about ninety-five per cent. of all cases requiring operative treatment that came under my observation. I use a general anesthetic only in those cases where extensive operations are to be done, such as excisions or resections, or where sutures are to be employed; where

I do not know in advance exactly what is to be done before operating, where there are any complications or conditions that would prevent thorough or complete work; or in the presence of pus, where the infection may be spread when injecting the solution for the production of local anesthesia.

The following conditions can be successfully operated upon under the influence of local anesthesia: complete, radical removal of external, internal and thrombotic hemorrhoids; fissure ani, ulcers, hypertrophied papillæ; diseased crypts of Morgagni; some forms of fistulæ; some forms of prolapsus ani; polypi; impaction of feces and removal of foreign bodies; dermoid cysts, and the modified Ball's operation for pruritis ani. Dr. Hirschman (2) says he is convinced that there is no case of hemorrhoids so severe that it cannot be successfully operated upon under local anesthesia, and he recommends as the standard anesthetic, one of the proved local anesthetics now so commonly used.

The object of this paper is merely to relate my experiences with what to me appears to be the safest and most reliable method of employing local anesthesia in rectal operations, and to elicit a sufficient amount of discussion so that we may be able to start some constructive work in proctology. Perhaps, besides reading papers and attending clinics at our meetings, we may reach a point where we can definitely agree among ourselves and then let the medical profession at large know that the American Proctological Society has accepted this, that, or the other method as the standard method of operating upon this, that, or the other condition, or that we have accepted a certain method of local anesthesia, or a certain local anesthetic as the anesthetic of choice in certain rectal operations.

CONCLUSIONS

1. Up to the present novocaine one half per cent. with adrenalin three minims to the ounce is the safest and most satisfactory solution for the production of local anesthesia in anorectal operations.
2. The circumscribed injection of the anal tissues blocks the sensation areas most satisfactorily for complete anesthesia, and a thorough relaxation of the sphincter muscles.
3. Stretching of the sphincter or dilating the anus becomes unnecessary.
4. The method of anesthesia described above can be successfully employed in about ninety to ninety-five per cent. of all anorectal disorders requiring operation.

Seborrheic Diathesis*

MOSES SCHOLTZ, M.D.,
Los Angeles, California,
Dermatologist to the Post-Graduate School, Los Angeles Medical Department, University of California.

It is a trite but ever true medical observation that a spectacular and rare disease attracts a good deal more attention than one that is common and prevalent, though the collective total of pathological significance of the latter may far exceed that of its sensational but rare rival.

Seborrhea is just one of those common, everyday clinical conditions that are so prevalent as to be ignored by the general profession.

DEFINITION

The general consideration of seborrhea can be properly preceded by a definition. What is seborrhea? The common conception is that seborrhea means greasy or oily skin. This conception is correct so far as it expresses the most familiar and elementary clinical features of it, but clinical manifestations of seborrhea are too varied and numerous to be reduced to this simple conception. The important feature of seborrhea which is commonly overlooked is its tendency to attack the same individual at different ages—in fact, in some cases pursuing an individual from the cradle to old age, assuming different clinical types according to biological characteristics of that age. In other words, seborrhea, as a clinical synthetic unit, is not simply a local dermatosis subject to control by various systemic factors, but a congenital or hereditary tendency to present certain clinical skin manifestations under the influence of certain dietetic and metabolic factors. This tendency is best expressed by the term seborrheic diathesis.

THE SEBORRHEIC INFANT

The seborrheic person is born with a milk crust on his scalp, which is the first evidence of the seborrheic diathesis. Commonly, it is considered as an unduly delayed remnant of vernix caseosa, but its persistency betrays its constitutional origin. Shortly the seborrheic baby begins to gain weight and to deposit fat. His scalp and face present eczematous areas. These eczematous areas differ from the ordinary type of infantile eczema by the greasy yellow crusts, easily detached, and by a tendency to spread from the scalp down, on the face, neck and trunk. This feature constitutes the most striking characteristic of seborrheic eczema, and this alone is sufficient for a correct differential diagnosis. The seborrheic element in infantile eczema was recognized by pediatrists only in a general way, largely from a dietetic point of view. The etiological factor of excessive fats and carbohydrates in infantile

*Read before the Los Angeles County Medical Association, March 1, 1923.

eczema was well established, and dietetic corrections in this direction were used as a routine. What pediatrists, with very few exceptions, did not recognize, is the clinical and morphological difference in types of eczemas due to the excess of fats and starches, and those due to proteid anaphylaxis. Through lack of this recognition, they lose diagnostic indications and the therapeutic advantage of local antiparasitic applications to which seborrhea is peculiarly responsive.

What percentage of infantile and children's eczema is of seborrheic origin can not be answered even approximately, as no statistical data on this point are available. In fact, a definite answer can be hardly given, as there are several mixed forms in which seborrhea is secondarily engrafted on anaphylactic eczema.

SEBORRHEA IN THE ADOLESCENT

After getting over his eczema of infancy and childhood, a seborrheic individual may stay clean until the next deep biological upheaval in his body—the approaching of puberty. The awakening of sex power lays heavy claims on the organ which is the weak spot in a seborrheic—the skin and particularly the pilosebaceous glands. As a reaction to this excessive demand on the skin acne of the face and seborrhea of the scalp develops in the seborrheic.

ACNE VULGARIS

Acne vulgaris, as is well expressed by its name, is so common as to be looked upon by many laymen as a physiological phenomena. Many practitioners consider it below their dignity to treat cases of acne. Yet many acne patients suffer not only from vanity but are actually handicapped in occupational and social pursuits. Anyone who has seen severe and neglected cases of acne, particularly of the indurated and cystic type, will agree that a case of severe acne is a serious affliction worthy of the best clinical skill and judgment. Deep multiple scars of misreated acne are a permanent disfigurement which can be easily avoided through timely and proper care. The duration of acne varies from two to five years. In a majority of cases it improves as the patient gets older and the stress of awakening puberty subsides.

SEBORRHEA OF THE SCALP

In many cases, simultaneously with acne, or sometimes with the subsidence of it, seborrhea of the scalp develops in one of the three stages. In the beginning seborrhea of the scalp presents merely dry dandruff—socalled pityriasis simplex. In this stage the hair is not affected. If unchecked this stage merges into the next stage—pityriasis steatoides, when dandruff scales become greasy and heavy. Still farther the process passes into the third stage—seborrhea oleosa—when the scalp becomes diffusedly oily.

The last two stages usually affect the nutrition of the hair and slowly but surely lead to permanent alopecia. Seborrhea of the scalp is easily the greatest single cause of baldness of the human race.

Women suffer a good deal less from seborrhea alopecia, partly because longer hair hides the cosmetic results better and partly because the female scalp apparently possesses a greater resistance to fat deposits in the hair follicles.

SEBORRHEIC DERMATITIS

Seborrhea being pathologically a low grade inflammation, it is easy to see how on the slightest provocation it can be stirred up into an active inflammatory state and turn into seborrheic dermatitis or eczema. Seborrheic dermatitis is quite a common condition. Characteristically it creeps down from the scalp below the hair line and may attack far distant parts of the body. Most common locations are: the face, behind and in front of the ears, sternum, intrascapular regions and genitals. Seborrheic eczema is more superficial and shows more sharply defined borders than ordinary eczema. Often patches of seborrheic dermatitis show circinate and festooned edges. At the same time it shows a remarkable tendency to recurrence. Due to low resistance the seborrheic skin is susceptible to secondary infection by staphylococci and streptococci, and seborrheic patches often present impetiginous appearance.

SECONDARY SEBORRHEA

It is important to remember that seborrheic contagium is mobile and easily spreads on already diseased areas. Because of it seborrhea is often seen on psoriatic patches. In fact, the association of seborrhea and psoriasis is so constant as to suggest some pathogenic relationship between the two. Seborrhea is also commonly seen engrafted on syphilitic lesions which accounts for the yellowish greasy appearance of many late secondary syphilides.

ROSACEA

As the seborrheic person passes over the age of acne and approaches the fourth decade he or she has a tendency to develop another chronic dermatosis, namely rosacea, commonly called acne rosacea, as in most cases it is associated with acne throughout; in other cases seborrhea develops at a later stage. Rosacea is characterized by permanent venous dilatations and acneiform eruptions localized in the socalled flush area of the face. Rosacea is the first evidence of retrograde changes of the normal tonus and vitality of the skin, the first beginning of the senility of the skin.

Rosacea is usually progressive and incurable, though it can be held in abeyance for many years under rational care. People with florid complexions —the lay term for seborrhea, are the habitual victims of rosacea.

Rosacea is controlled by the same systemic and dietetic factors and yields to the same therapeutic measures as acne and seborrhea.

SEBORRHEIC KERATOSES

The next and the last link in the biological cycle of a seborrheic are seborrheic warts, also known under the name of senile keratoses. Seborrheic keratoses develop from middle age up, in typical seborrheic locations, such as the face, scalp, neck, chest or back, as greasy, grayish yellow, brown or slate colored, slightly elevated scaly lesions. The great clinical importance of seborrheic warts is that they have often a tendency to turn into keratoses and still later into epitheliomata and can be

regarded as a true type of precancerous lesions. While it is true that only a small percentage of seborrheic keratoses degenerate into epitheliomata, their number is so infinitely large that in all conservatism many thousands of epitheliomata can be credited to this source. Yet not only laymen but even the profession at large pays very little attention to this type of precancerous lesions.

One of the best illustrations how seborrhea prepares ground for epitheliomatous degeneration was pointed out by D. W. Montgomery (1), of San Francisco, in the frequent association of the dry seborrheic lesions of the lip with subsequent development of epitheliomata.

CLASSIFICATION OF SEBORRHEIC MANIFESTATIONS

To recapitulate briefly, seborrhea starts in infancy as milk crust and continues as infantile seborrheic eczema; in adolescence it breaks out as acne vulgaris and diffuse seborrhea. Seborrhea of the scalp leads in many cases to permanent alopecia and brings out many attacks of seborrheic dermatitis. Later in life it brings out acne rosacea and still later produces seborrheic or senile keratoses which lead to epitheliomata. It is a matter of wonder and regret that various clinical forms of seborrhea cited above are still looked upon by many dermatologists as separate clinical entities and not as clinical variations of the same pathological unit. Classification offered by many writers is too chaotic and confusing to be considered here. The best and the most comprehensive conception of seborrhea has been offered so far by the French dermatologist, Darier (2), to be considered later.

DIAGNOSIS.

Clinical recognition of seborrheic skin manifestations presents no difficulties. Seborrheic skin is recognized by dirty yellow, brownish or grayish tint, greasiness or oily feel, dilated pilosebaceous openings and comedones; the inflammatory types by yellow heavy greasy scales, well defined borders, often circinate, superficial character of the patches, tendency to spread downward from the scalp beyond the hair line and centripetal localization. Most often seborrhea has to be differentiated from eczema, ringworm, syphilis, psoriasis and pityriasis rosea.

ETIOLOGY AND PATHOGENESIS.

Parasitic theory.—The etiology of seborrhea is still a matter of controversy and confusion. The prevailing theory is parasitic. Seborrhea is held to be infectious because certain microorganisms are constantly found in seborrhea. These are: Bacillus seborrheicus of Sabouraud, spores of Malassez, bottle bacillus of Unna and polymorphous coccus with gray colonies described by Sabouraud which is apparently identical with morococcus of Unna.

However, the specificity of the bacteria is not proved as they have been found by Schamberg also in nonseborrheic skin. Apparently these bacteria become pathogenic only under certain circumstances found in seborrhea. In other words there is more reason to say that the alleged microorganisms are responsible rather for complications of seborrhea such as seborrheic dermatitis, than for seborrhea itself.

Endocrinous theory.—Lately with the new ideas of the modern research, a new interpretation was advanced—endocrinous. The fact that acne and seborrhea start at the time of the greatest physiological activity of endocrinous glands, essentially gonads, and also the fact that acne is often caused in females by dysmenorrhea, gave rise to the endocrinous origin of seborrhea. The endocrinous theory, however, does not account for all clinical forms of seborrhea, as some of them, such as acne rosacea and seborrheic keratoses, arise and continue at the physiological epochs showing not only the lack of increase of endocrinous activity, but more so, the actual decrease of it. Endocrines can be accepted as a contributing factor at certain physiological epochs toward precipitating the development of seborrheic manifestations but not as a basic etiological factor of seborrheic diathesis.

Metabolic theory.—In spite of constant findings of certain microorganisms in seborrheic lesions, and in spite of the ready response of seborrheic lesions to antiparasitic applications attested by all observers, clinical experience points strongly to the great pathogenic importance of systemic etiological factors in seborrhea. It is a well established empirical observation, often quoted by the patients themselves, that an excess of starches, fats and sweets in diet brings on an acne outbreak. Aggravation of acne by constipation and digestive disorders is also well known clinically.

The latest research in metabolism is supplying more and more evidence that seborrhea is essentially a metabolic disorder. Thus Levin and Kahn (3) in their biochemical studies of skin diseases have found hyperglycemia in over fifty per cent. of acne cases. This observation has been confirmed by Highman and Schwartz (4). Levin and Kahn have also found mild acidosis in about thirty per cent. of their series of twenty-three cases of acne. Acidosis in seborrhea has been found still earlier by English observers, Barber and Semon. These observers have found that vigorous administration of alkalies has controlled seborrheic lesions. D. W. Montgomery (5) of San Francisco, one of the best American students of seborrhea, is the authority for the statement that many patients with seborrheic eczema have enlargement of the liver, possibly due to fatty infiltration or the excess of stored glycogen. On the other hand, it is an old clinical observation that in anemia and various wasting diseases, such as tuberculosis, seborrhea and acne are produced through a defective oxidation, so called acne cachecticorum.

Infantile seborrhea as pointed out by Montgomery is due to a rapid absorption and deposit of milk fat in the skin. Skin, as Montgomery puts it well is the largest fat using organ in the body and can be looked upon as an immense fat excreting gland. In the light of all these data, seborrhea should be regarded as a metabolic disorder particularly of fat but it may be caused also by a faulty assimilation of carbohydrates and sugars.

SEBORRHEIC DIATHESIS

The fact that clinical manifestations of seborrhea present such a multiformity of lesions as to elude at the hands of many writers the recognition of

common origin and still more the fact that these clinical types of seborrhea occur at definite biological epochs and have a tendency to attack the same individual at these periods seems to me points strongly to the deep nature of metabolic derangement conducive to seborrhea. It seems to me that an assumption of seborrheic diathesis will explain many clinical problems pertaining to seborrhea.

The idea of seborrheic diathesis has been definitely formulated and promulgated by English writers, Barber and Semon (6), in 1919. However, the clinical conception of it has been closely approached and given under different names by two earlier writers.

EXUDATIVE DIATHESIS.

The first is exudative diathesis promulgated by Czerny in 1909 and generally accepted by pediatrists. Exudative diathesis signifies a congenital or hereditary metabolic fat derangement characterized by a strong tendency to eruptive lesions on the skin and mucous membranes. The skin manifestations, as they are described by Czerny, begin as a persistent milk crust and gradually develop into eczema, spreading from the scalp down on the face and neck, commonly involving intraauricular folds and leading to intertriginous lesions in body folds. This description so well fits in a seborrheic syndrome and well shows that seborrhea constitutes a very important if not the main feature of exudative diathesis. It is but natural that Czerny, being a pediatrist and not a dermatologist, has not given much attention to morphological features but laid main stress on the systemic factors.

KEROSIS.

The second and still broader, in fact the most comprehensive and thorough conception of seborrheic diathesis so far advanced, has been created by the French dermatologist Darier, who suggested a synthetic term—kerosis—to comprise all clinical manifestations and clinical types of seborrhea. It is most singular that Darier having incorporated every clinical type of seborrhea and having given a perfect description of each has found it necessary to coin a new name, kerosis—insisting that seborrhea is merely a complication and only one of the features suggested by him, kerotic diathesis. Yet he emphasizes as the most significant feature of his kerosis its tendency to attack individuals at different biological epochs and in describing it simply enumerates all the seborrheic types cited above. Darier's conception of kerosis has been, apparently, interpreted also by others, as seborrheic diathesis. Thus Barber and Semon in formulating their hypothesis of seborrheic diathesis have based it entirely on Darier's conception of kerosis.

SEBORRHEA AS DIATHESIS.

To me seborrhea as a clinical phenomenon has every earmark and characteristic of a metabolic dyscrasia or diathesis. It starts from birth and may pursue a person to old age. Different clinical types of seborrheic diathesis occur only at certain definite biological epochs showing a deep metabolic and biochemic basis of its origin. Seborrhea is definitely connected with fat metabolism and is controlled by dietetic factors. Various manifestations of seborrhea may present a striking difference of clinical pictures, yet they all can be reduced to the same etiological factors and present the same pathological substrate deposition of fat in the skin. As any other diathesis, seborrhea can vary in degree and intensity. It can be mitigated and controlled by biological environment of an individual and by therapeutic measures. It may be apparent at early infancy or it may break out at a later period. It may be in a latent or dormant stage for many years, and then suddenly, under physiological upheaval or pathological associated factors break out in acute and severe form. It may strike one individual in the family or may be hereditary and affect several members of the family.

The bacteriological findings and the clinical response of seborrheic lesions to antiparasitic applications do not invalidate to any extent the metabolic hypothesis of seborrhea. If we remember that the surface of the skin is normally infested with very luxurious and multiform bacterial flora it is readily seen how with the disturbed nutrition and the lowered resistance of the skin microorganisms become pathogenic, increase in virulence and lead to active seborrhoid lesions or mixed infections with staphylococci and streptococci.

CLINICAL SIGNIFICANCE OF SEBORRHEA.

The clinical scope of seborrhea can be readily understood from numerous clinical manifestations described above, particularly if it is remembered that each one of these clinical forms belongs to the most commonly met with dermatoses. Taking collectively all clinical variations of seborrhea, it easily leads all other dermatoses in numbers. Its victims are innumerable but the damage caused by it is not realized because of its chronicity and insidious mode of development.

The ravages of seborrhoic diathesis are not only limited to many thousands of infantile eczemas and later in adolescence to millions of sufferers from acne and seborrhea of the scalp leading to permanent alopecia. Recurrent attacks of seborrheic dermatitis with secondary staphylococcic and streptococcic infection present a most distressing and stubborn condition. Still later seborrheics are susceptible to another permanently disfiguring condition of acne rosacea leading to telangiectases and occasionally to rhinophymatous tumors.

The most serious damage and yet the least realized by the general profession is the tendency of seborrheic lesions to degenerate into precancerous lesions. As emphasized above, seborrheic, i. e., senile keratoses are the most frequent cause of skin cancer. The frequency of skin cancer, unrecognized and untreated, metastasizing in the lymphatics has not been and can never be definitely established. For this reason the preventive importance of destruction of seborrheic precancerous lesions is self evident. Besides the enormous clinical interest seborrhea deserves attention at the hands of the general profession from a purely theoretical scientific point of view. The steadily accumulating evidence of systemic changes cited above, found in seborrhea, such as hyperglycemia, acidity, enlargement of the liver, etc., should interest and stimulate the internist and the student of metabolism to study

seborrhea as the skin manifestation of deep metabolic disorders.

SUMMARY

1. Seborrhea presents a large number of clinical types related etiologically and pathologically, but differing widely in morphologic features.

2. Seborrhea has a tendency to attack the patient at different physiological epochs in a definite morphological sequence.

3. Seborrhea is a metabolic diathesis, congenital or hereditary, and the bacterial invasion is a secondary development.

4. Seborrheic lesions are controlled the best by an appropriate general régime, dietetic corrections combined with local antiparasitic applications.

5. The seborrheic patient should be watched at different epochs of life for a possible development of seborrhoids corresponding to his age.

6. Seborrheic manifestations should more often be considered by the internist as surface indications of metabolic derangements. Such study may not only increase the efficiency of dermatological treatment but also may clear up the pathogenesis of many obscure visceral lesions due to faulty fat or carbohydrate metabolism.

Prolapse of the Ventricle of Morgagni

PROFESSOR SABRAZES and ANDRE LUSSAN
Bordeaux, France
Faculty of Medicine of Bordeaux

(*Concluded from page 300*)

DEFINITION

By the term of prolapsus of Morgagni's ventricle is meant a more or less voluminous tumor of the larynx, red in color and smooth in surface, appearing to make its exit from the ventricle. The tumor has a broad base of implantation, distinctly separated from the ventricular band, overlying the corresponding vocal cord covering it more or less completely.

Case I.—Male, aged thirty-nine years, always enjoyed good health; no tuberculosis, no syphilis. He was seized by hoarseness which lasted only five or six days. A year later, following severe sneezing, he experienced severe pain deep down on the left side of the throat. The following day he was hoarse and this hoarseness continued to increase. When we saw the patient a few weeks later the entire larynx was red and between the left vocal cord and ventricular band was a dark red mass almost covering the entire cord. The cords did not come together. The right side of the larynx was perfectly normal. An appropriate treatment was prescribed, but the laryngoscopic picture viewed upon several occasions did not change, although symptomatically there was improvement. He consulted another physician who diagnosed tuberculosis of the larynx and gave a bad prognosis.

Eleven months later the patient again entered the clinic and an attempt was made to reduce the congestion with a solution of adrenaline. The mucosa became pale for a few hours but the hoarseness was not relieved. It was then decided to remove the mass with cutting forceps which was accomplished in two séances, after which the voice became almost normal, but the hoarseness recurred in about two months. It was then found that an almost identical lesion was present on the right side, but the former prolapse of the left ventricle had been cured. The right sided prolapse was in turn removed with ease. The voice was at once restored to normal in five or six days. The patient was seen five months later. The larynx was normal, likewise the voice.

The bits of tissue removed were examined by Prof. Sabrazès. They were covered with stratified pavement epithelium consisting of six to eight layers. The chorion was transformed into an infiltrate of embryonal mononuclear and polynuclear embryonal cells having no tendency to form islands, and were densely scattered throughout the preparation. The same type of cell was found in the interstices of the epithelial lining. There were few vessels; the capillaries and venules met with presented inflammatory lesions of the internal tunic—swelling and multiplication of the endothelium. At no spot were giant cells detected, nor were there any foci of necrosis.

Diagnosis: Débris of the mucosa of Morgagni's ventricle, presenting thickening and inflammation.

PATHOLOGY

From what is known of the reported cases one may assume that the ventricle becomes turned inside out like a glove finger and projects through the ventricular orifice. Fränkel has rightly remarked that the motives favoring this interpretation are, from the viewpoint of anatomy, the possibility of reducing the mucosa, and clinically the sudden appearance of the tumor.

To be sure, the sudden appearance of the tumor is noted in many cases, but in quite a number of other reports no such mention is made and in analyzing the histories of a number of patients it will be found that hoarseness had been present for a number of days. Therefore, this symptom is not necessary for the diagnosis of prolapsus of Morgagni's ventricle and when encountered permits of another explanation.

The only proof that a turning inside out occurs

would be an immediate demonstration, but this is an impossibility. For this it would be sufficient to consider the appendix and first of all the way in which it separates itself at a right angle from the ventricular cavity, a sort of spur directed backwards and outwardly, thus constituting a means of fixation of the ventricle. Its sinuosities and accessory cavities are all so many fulcrums solidly built into the surrounding connective tissue which is so abundantly supplied with glands and which becomes mingled with the perichondrium so gradually that it is often impossible to detect where one begins and the other ends. Consequently the appendix is solidly united to the epiglottis and thyroid cartilage in front, to the arytenoid cartilages behind, so that it seems to us an impossibility for it to break away from its attachments and to prolapse outwardly.

On the other hand, without the appendix, only the posterior third of the ventricular cavity could become everted, but as long as the appendix enters into the cavity of the ventricle, that is to say, into the two anterior thirds of the latter, eversion cannot take place without drawing the appendix along with it. Therefore, anatomically it is quite logical to doubt the possibility of a total prolapse of the mucosa of Morgagni's ventricle, as many observers are inclined to admit.

If on account of these anatomical relations and its histological structure prolapse of the ventricle is impossible, to what cause can one attribute the more or less large tumor visible in the larynx?

Fortunately there have been some examinations of the larynx postmortem and these have shown clearly that what had been supposed to be a prolapse of the ventricle was quite another affair, because the ventricular cavity was preserved; it is only decreased in size by a more or less voluminous swelling springing from one of the walls of the ventricular cavity and projecting between the ventricular band and the vocal cord.

Here, for example, is Fränkel's description of a postmortem examination made by him. "On each side, the entire ventricular opening was filled by a swelling covered with mucosa, distinctly separate from the vocal cords and ventricular bands by a well marked sulcus. These swellings, the right being more marked than the left, could be reduced, but afterwards projected again. The laryngeal mucosa was thickened. The right side was then divided in the middle of the vocal cord by a frontal incision and then one saw very distinctly between the ventricular band and vocal cord, at a point corresponding to the normal ventricle and its appendix, that the ventricular cavity was reduced in size by a swelling starting from the lateral wall of the ventricle and upper surface of the vocal cord and projected forward between the ventricular band and vocal cord like a spur. Microscopical sections were not good because the specimen had become deteriorated by soaking in bad alcohol, but nevertheless one could distinctly see that there was considerable hypertrophy of the connective tissue not only in the swelling itself, but also in the vocal cord."

Chiari also described some specimens in which a fold of mucosa starting from the posterior lip of the entrance of the ventricle penetrated the appendix forming a large projecting mass in the ventricle. The specimen was taken from a subject who died from locomotor ataxia with atrophy of the vocal cords. Chiari says: "On a frontal section passing through the ventricular band and vocal cord there existed a projection about two millimetres long and three millimetres thick, starting from the external edge of the entrance of the appendix and bellying into the ventricle. Its lower end, very slightly club-shaped, was distant only five millimetres from the ventricle. This swelling appeared to be the frontal section of an hypertrophied fold of mucous membrane, composed of a rather thick connective tissue with round and fusiform cells. The round cells at the clubshaped end formed a follicle five millimetres long and two millimetres broad. The swelling was entirely covered by ciliated epithelium, the cilia being well preserved. There were no glands."

It will be seen that this description is in accord with Fränkel's ideas on the subject. Chiari also examined the specimen removed surgically in another case of socalled prolapse—and demonstrated that the tissue was an edematous hypertrophied fold of mucosa coming from the wall of the ventricle and projecting through the ventricle.

Koschier examined bits of tumors removed from sixteen cases of socalled prolapse of Morgagni's ventricle and he states that they were mostly large tumors more or less completely covering the vocal cord. He did not regard as prolapse the small, smooth elevations on the lateral parts of the mucosa so frequent on the upper surface of the vocal cords in chronic catarrh, tuberculosis, and syphilis of the larynx. "In these sixteen cases the tissue removed was covered by stratified pavement epithelium, sometimes considerably thickened, and cylindrical epithelium was rarely present. The tumor itself was composed of soft connective tissue, very rich in cells at some spots with rather large reticulated spaces. It was towards the periphery on the side of the epithelium and in the neighborhood of rather numerous vessels that the tissue was rich in cells. In all the specimens there was distinct edema of the tissues and recent or old hemorrhagic foci were also seen in some. In no specimen could neoformed mucous glands be discovered and at those spots where they did exist normally they did not present any morbid change."

Koschier's examinations do not give us any exact data as to the relationship of the tissue examined to the surrounding structures, but they do enlighten us as to their histological makeup, namely: 1. There was a catarrhal inflammation of the mucosa with more or less abundant round cell infiltration, especially in the neighborhood of the neoformed dilated vessels. 2. A hyperplasia of the subepithelial connective tissue, which composed the principal mass of the tumor.

In Lichtwitz's case the ventricular mucosa was thickened and inflamed and we cannot admit Koschier and Chiari's opinion who refuse to regard such cases as prolapse. Although these swellings are not large and do not cover the entire vocal cord or obstruct the glottis, they nevertheless are produced by the same process and the only difference that can be made between them is merely a question of degree.

Besides the epithelium and connective tissue, the ventricle also contains glands which, for the most part, do not undergo any pathological change. But it

can readily be understood that from the mere fact that they empty their secretion into the ventricular cavity they may participate in the inflammatory process. The excretory duct may become occluded and the gland continue to secrete, hence the ducts become dilated with the result that more or less voluminous cysts develop. Such was the condition of affairs in a case reported by Stoerk, of a male he operated upon three times for a tumor protruding through Morgagni's ventricle. Histological examination showed: 1, Severe chronic inflammation with hypertrophy of the subepithelial connective tissue; 2, cystic degeneration of the excretory ducts of the mucous glands. The first tumor removed was a large mucous cyst surrounded by smaller ones; the second and third were composed of numerous agglomerated small cysts. In this case the development of the prolapse was entirely due to the cystic dilatation of the glands and the relapses are to be interpreted in the same way.

Besides the sixteen cases already referred to, Koschier reports another case exactly like Stoerk's except that there was no recurrence. Histologically the tumor removed was oval, smooth, and with a rather long insertion. On section a thin walled cyst was found with a pedicle filled with a clear serous fluid. The pedicle was made up of loose connective tissue containing numerous mucous glands; in spots it was lined with cylindrical epithelium. Excepting a slight small cell infiltration of some mucous glands these did not offer any morbid change. Others presented cystic dilatation and were filled with serous fluid. All the tissue was quite rich in vessels, most of which were gorged with blood.

The cyst was oval, six millimetres long by three millimetres in breadth. The walls were thin and the external surface was covered by rather thick pavement epithelium, while the internal surface was lined with a single layer of cylindrical cells. At one spot this epithelium was flattened to give place to a perfectly flat pavement epithelium. The wall of the cyst was made up of soft connective tissue containing many vessels gorged with blood.

Now, if it be recalled that glands in clusters are especially abundant in the upper wall of the ventricle which is formed by the lower aspect of the ventricular band, and particularly in the region near the appendix, it can readily be understood that it is above all at the upper part of the ventricle that inflammatory processes extending to the glands will result in cystic formation.

Nevertheless they may likewise be encountered in all the rest of the ventricle, but in a lesser degree, because the lateral and lower walls of the ventricular cavity are relatively poor in glands.

All things considered, the examination has shown that a portion of the mucosa is forced outwards on account of the inflammatory process, be it the mucosa itself, or the submucous tissue.

PATHOGENESIS

These swellings, which push the mucosa through the laryngeal orifice of Morgagni's ventricle, are the product of acute or chronic inflammatory processes. They may be engendered by general diseases or by neoplasms. But we shall leave aside those cases, which for us should not be regarded as prolapse. We have especially in view cases of prolapse having an inflammatory origin. The ventricular mucosa is not more privileged than other parts of the mucosa of the larynx. And what is more, on account of the immediate proximity of the vocal cords, it seems quite natural that inflammatory attacks, so common here, should have a tendency progressively to involve the neighboring structures, including the ventricular mucosa.

In reality, experience has confirmed that which reason would lead one to suppose. Studying acute laryngitis, Koschier pricked the larynx of a dog with a steel pin. On each side, the pin passed through the anterior third of the ventricles and at autopsy, besides an intense acute laryngitis, the swollen ventricular mucosa assumed a domeshaped mass covering the anterior part of the vocal cord, which behind appeared to be free over quite a considerable extent. The bright red tumor was soft and could be reduced partially into the ventricle by means of a probe.

In sections it was seen that the swelling, which was inserted on the lower part of the lateral wall of the larynx, was composed of loose connective tissue with large meshes and imbibed abundant serous fluid. In spots the serous collection has so distended these reticulated spaces that they gave the impression of irregular cavities filled with a collection. No hemorrhages could be detected. The covering of the swelling was everywhere stratified pavement epithelium. The swelling of the mucosa was due to inflammatory edema producing considerable bombing and its appearance in the interior of the larynx.

Before experimentally inducing this acute prolapse in dogs, Koschier had the luck to examine a male patient with an intense acute laryngitis in whom, within the space of twenty-four hours, a leftsided swelling of the mucosa developed, which covered the corresponding vocal cord. The swelling subsided with the laryngitis that had caused it.

Such is the history of Beausoleil's patient in whom an inflammatory swelling of the ventricular mucosa developed quite suddenly during an attack of acute laryngitis.

In these cases of acute inflammation the mucosa is inflamed and raised up by an inflammatory exudate. But in subjects exposed to irritating dust, in those who use the voice immoderately—speakers, singers—and especially those who are obliged to cry in the streets in all kinds of weather, a soil will develop eminently favorable for the development of chronic laryngitis, hence a chronic inflammation of the ventricular mucosa. The inflammatory process does not at the onset give rise to these tumors that the early observers took for a total prolapse of Morgagni's ventricle. In its early phase, chronic catarrhal inflammation assumes more modest proportions and its evolution can be conveniently divided into three phases as follows:

The first phase has been described by Stoerk, who met with it more particularly in singers. The vocal cords present their usual whiteness, but closer examination shows redness confined to their lateral aspect which forms the entrance to Morgagni's ventricle, and the mucosa lining the ventricle likewise presents the same tumefied red aspect. Instances such as these are far more common than is generally supposed, and we have seen several examples. It is evident, however, that the diagnosis is difficult in

ordinary subjects, while singers, who are accustomed to control their voices, know when some slight change has occurred, imperceptible in people who have had no vocal training.

The second phase, the continual irritation of the ventricular mucosa, provokes a sharp irritation of the connective tissue which reacts by proliferation. Hence a swelling results, formed by more or less inflamed mucosa and subjacent connective tissue undergoing proliferation, which discretely appears in the entrance of Morgagni's ventricles.

The third phase is reached when these swellings are drawn in and pushed out in the act of breathing. The return circulation, interfered with by the connective tissue proliferation, encounters a still greater obstacle from compression of the swelling against the walls of the larynx. Hence a rapid increase in the size of the tumor ensues and soon it assumes the aspect of a polypus, which may occlude the glottis.

It would clearly be an exaggeration to regard the first phase as one of prolapse, and it would also be an exaggeration to reserve this term for the third phase of the process only. One can readily understand that the early observers gave the name of prolapse only to large tumors almost completely occluding the lumen of the larynx, but we believe that it is perfectly logical to regard as prolapse the process in its second phase because a part of the mucosa pushed out of the ventricular cavity escapes through the laryngeal orifice of Morgagni's ventricle and prolapses into the lumen of the larynx; therefore it is merely a question of degree.

We have already stated that we are especially concerned with acute prolapse, but we cannot ignore instances of the process met with in general constitutional affections and intraventricular neoplasms. Cases of this description may assume the characters of true prolapsus of Morgagni's ventricle and from the diagnostic viewpoint they cannot be overlooked.

In tuberculosis and syphilis, one frequently meets with swellings partially covering the vocal cords and appear distinctly to come out of the ventricle. These swellings, produced by gummata or tubercles, are very common, because the same morbid condition exists in the ventricle as in the other surrounding structure. As the affection progresses, the infiltration of the surrounding tissues soon makes examination impossible and the ventricular prolapse cannot be detected. In some cases the presence of ulceration on the vocal cords or ventricular bands determines an inflammation of the mucosa with a true prolapse following the mechanism we have described.

These cases are very difficult or even impossible to differentiate and among them a place should be made for many intermediary conditions which precisely constitute both the difficulties and clinical interest. Ventricular prolapsus observed in tuberculosis and syphilis is frequent, as the literature shows, and we would add the following case in which a pulmonary localization preceded the laryngeal lesion in the form of a voluminous tumor produced by intraventricular tubercles.

Case II.—Male, aged twenty-six years, had had hemoptysis at the age of twenty-three, since which time he had had frequent attacks of capillary bronchitis. Seventeen months ago hoarseness developed and latterly there had been complete aphonia. Manifest signs of pulmonary tuberculosis were present. But in spite of the lung lesions, thanks to overfeeding, the patient had not lost strength. He was distressed by the aphonia and difficulty in breathing.

Laryngoscopic examination revealed a cauliflower growth the size of half a hazelnut, which appeared to project from the left ventricle of Morgagni and partially occluded the lumen of the glottis. The left vocal cord was not visible except at its anterior and posterior ends. The remainder of the larynx appeared normal, with the exception of the interarytenoid mucosa, which presented a superficial erosion. With cutting forceps the tumor was removed. The result was immediate. The patient's voice became clear and breathing was free. Laryngoscopy showed that the left vocal cord was entirely free and looked normal. Eighteen days later some granulations were removed from the entrance of the ventricular orifice. One month later the voice was still clear and the breathing good. A year later the patient died from the pulmonary lesions.

We believe that Koschier is too exclusive when he confines the term of prolapsus only to large tumors covering the entire vocal cord, and that he is wrong in considering as a prolapsus of Morgagni's ventricle the appearance in the larynx of ventricular mucosa pushed out by a neoplasm on the ventricular mucosa. All this seems to us exaggerated and can only lead to confusion if we may judge by what takes place in the other structures.

All things considered, observers such as Mayor, Gouguenheim, and others, call attention to the fact that prolapsus of Morgagni's ventricle is met with in syphilis, tuberculosis and cancerous cachexia, but they are wrong when they maintain that these affections are the only cause of the prolapse. We even believe that the term prolapsus should be exclusively reserved for cases in which the appearance of the ventricular mucosa in the larynx is simply the result of a catarrhal process, because when the mucosa prolapses in syphilis, tuberculosis, or neoplasms seated in the mucosa of the ventricle, it is impossible by mere laryngoscopic examination to distinguish if the parts seen represent the inflamed ventricular mucosa or a portion of the neoplasm itself. The distinction is clearly important for both treatment and prognosis. Cancer is fatal, syphilis is cured by treatment, while confining the term prolapsus strictly to inflammatory processes the tumefaction present offers no other gravity than the resulting interference with the normal functions.

SYMPTOMATOLOGY.

From the clinical viewpoint prolapsus of Morgagni's ventricle gives rise to three phenomena, viz., dysphonia, dyspnea, and paroxysms of cough.

Dysphonia.—From the onset there is a fatigued voice, and for this reason singers will apply at once for treatment. At this phase no prolapse can be seen; there is a redness limited to the lateral aspect of the vocal cord. But the fatigue of the voice increases and the case then enters the second phase of ventricular inflammation. A true dysphonia ensues, sometimes reaching aphonia. It even is curious that the presence of these narrow swellings, which cover only a small portion of the vocal cords, produce a dysphonia often more considerable than tumors of the third phase. This fact cannot be explained only

by mechanical interference with the vibration of the cords and paresis of constrictors must play a part.

Dyspnea.—If the process is not treated, the third phase will be reached in which a large tumor completely occludes the orifice of the glottis and to the dysphonia, a more or less considerable difficulty in breathing will become added.

Paroxysms of cough.—Laryngoscopy will reveal a unilateral or bilateral tumor of the larynx, varying from a slight elevation covering the vocal cords to those enormous tumors which totally occlude the orifice of the glottis. The tumors are smooth, covered by a red, shining mucosa and are distinctly separated from the ventricular bands by a narrow sulcus. Soft in consistency, these swellings, with a large base, may be totally or partially reduced under the ventricular band, but, generally speaking, the reduction will not last and the tumor again appears. It is, as we have said, an edematous, hypertrophic swelling. The probe will reduce the inflammatory edema and the tumor, reduced in size, returns to the ventricular cavity, but immediately the infiltration of the reduced swelling returns and the ventricular mucosa again protrudes into the lumen of the larynx.

The tumor, being movable, acts like a valve during respiration and during phonation or coughing it increases in size and seems to protrude still further. These phenomena, which are very distinct in large tumors, are less apparent when the inflammatory process is still in the second phase. Nevertheless, even then the tumor may be seen to come out of the ventricle during phonation and distinctly cover the vocal cord. When the process is still in the indefinite stage between the first and second phase, something can be seen interposed between the ventricular band and vocal cord when the patient coughs, but returns into the ventricular cavity when the cough subsides as was seen in one of our cases. This fact explains the sudden appearance of the tumor in some of the reported cases. But following some effort on the patient's part, the tumor, which for some time freely appeared and disappeared, participates in the congestive attack in the larynx, suddenly projects and there remains if it is of sufficient size.

DIFFERENTIAL DIAGNOSIS.

The first phase need not be considered as it cannot be regarded as prolapsus. In the second phase the chief difficulty is the examination, on account of the hyperesthesia resulting from the laryngeal inflammation. One is struck first of all by a swelling seated on the lateral aspect of the larynx. It may be on one or both sides and appears distinctly seated between the vocal cord and ventricular band from which it is separated by a narrow sulcus and the question arises whether the lesion is syphilitic, tuberculous, or a catarrhal process. The laboratory will quickly settle the question. In the third phase there is a polypoid growth hanging in the orifice of the glottis, but it may be difficult to decide whether the lesion is a polypus, myxoma, papilloma, or a growth projecting from the ventricle. In the latter circumstance one must distinguish between a tumor exclusively composed of the mucosa of the ventricle and a nonmalignant or malignant neoplasm inserted on some spot of the ventricular cavity.

It is especially in these difficult cases that minor data assume considerable importance and one must carefully ascertain the way in which the tumor has appeared, because a slow development would rather favor the diagnosis of a neoplasm, while a more rapid evolution would rather indicate a prolapsus of the ventricle. Finally, when the diagnosis is not possible, a biopsy of the tumor should be made.

TREATMENT.

This is strictly surgical and can be summed up in a few words. The morbid tissue should be removed by a cutting instrument or the galvanocautery. If the tumor is large, it may be removed in several séances. After removal the base of insertion of the prolapsed mucosa should be gone over with the galvanocautery.

Common Errors in Urinary Diagnosis*

WINFIELD S. PUGH, M.D.,
New York

In the days of the old gonorrhea clinic, with our general lack of methods of exact diagnosis, the many errors made were often excusable. With the advent the modern urology and its appreciation of more precise diagnostic methods the possibility of error has been greatly reduced.

The knowledge of cystoscopic and urethroscopic technic, the ureteral catheter and modern functional tests have been of the greatest possible value and have established urology on a firm basis. Modern urological instruments require considerable experience in their manipulation and the proper interpretation of what one sees. The modern methods of urine examinations are, however, within the reach of any worker in the field of medicine.

The average physician or surgeon either has not the time or the proper equipment to carry out the more advanced urological technics, but this is a greater reason why he should at least make use of the up to date methods of case recording, physical examination and complete urinalysis. By this means he will be able to arrive at an approximate idea of where the trouble lies and when beyond his sphere to refer it to the urologist.

We are fortunately rapidly getting away from the old idea, that urinary conditions, particularly those due to the gonococcus, are trivial affections. There are still some who attribute almost every urinary sign or symptom to the gonococcus and call the condition gonorrhea. These snapshot diagnoses are often unfortunate for the health of the patient and the reputation of the physician.

*From the James Buchanan Brady Urological Foundation of the New York Hospital.

The employment of rapid fire methods are not possible in the field of urological surgery and there is no domain of medicine in which painstaking effort is so necessary to arrive at a proper diagnosis. A considerable amount of time and care is also necessary in the preoperative and postoperative technics and it becomes early apparent to the student of urology that these technics are often vastly more important than the operative procedures.

I know of no other division in medicine and surgery that yields more satisfactory results and more grateful patients than urology when all of the necessary procedures are properly carried out. In one's office it may not be possible to carry out every detail, but a start should at least be made in that direction. It certainly is wrong to treat any patient after a casual inspection. A careful history, physical examination and a chemical and microscopical examination are always possible and should be employed; not only employed but carefully analyzed.

It is surprising how often the most elementary procedures are overlooked and thereby not only are the difficult cases missed but some of the most obvious are allowed to slip by. The following group of cases collected during the past few months well illustrates this point. In these case reports most negative data are omitted, as having no bearing on the reports.

CASE REPORTS

CASE I.—J. A., white, Italian, aged seven. Mother and father were living and well. There was no history of tuberculosis or malignant disease. The patient had had a natural birth, and had had measles at three years of age. About four weeks ago had an attack of sore throat, which lasted about a week and was treated with some home remedy. At present he complained of pain over left lumbar region extending toward the hypogastrium. The pain was not constant but appeared at least once a day and caused the child to cry out. There was also a lump in left inguinal region (inguinal hernia) which was said to enlarge during attacks of pain. This condition was diagnosed as renal calculus.

General inspection revealed a puffiness about both eyes, protruding abdomen, left inguinal hernia and considerable edema of both feet and legs. Cystoscopy revealed a bladder normal in every respect. Urine from both kidneys was acid, 1.025, contained an abundance of albumin, granular casts, red and white cells, urea about a half per cent., pyelogram negative. The sore throat in the history at once aroused suspicion and when it was found to be associated with edema of the lids and feet, it strongly suggested a postdiphtheritic nephritis. A throat culture was made and Klebs-Loeffler organisms found in almost pure culture. A diagnosis of postdiphtheritic nephritis was made. Condition cleared up by appropriate remedies.

The foregoing case, I believe, illustrates quite thoroughly not only the value of a careful history, but the proper analysis of it. It would have seemed difficult to overlook this case because the history was well taken and clear. In addition to that, as the late Dr. George Henry Fox would say, "It was written on the skin." The presence of what looked like a renal colic was adjudged sufficient for the original diagnosis.

CASE II.—C. H., white, male, thirty-six years of age; was born in the United States. The patient's father was living and well, his mother died of pneumonia at forty-two, one sister was living and well. He had had scarlatina in infancy, influenza in 1918, and no other illness aside from present ailment.

The patient had urethral discharge, urinary frequency, tenesmus and backache. He stated that he had acquired a Neisserian infection about eighteen months previously, which had improved and relapsed several times during that period. He insisted that he had always been regular in taking treatment and denied any venereal indiscretions. He said that about two or three weeks after the original appearance of the urethral discharge it subsided. At this time he stated there was also terminal hematuria and tenesmus. He had been to a number of physicians without securing any permanent relief.

This patient was referred to me as having chronic urethritis with the suggestion that I might help him by endoscopic treatments.

The first thing noticeable was that the patient's clothing did not fit him but seemed to hang rather loosely about his person. Loss of considerable weight was apparent and the patient said this was correct. He thought his loss of weight was incident to worrying about his condition. Sexual desire was increased but he feared to satisfy it. Facies were drawn but face was slightly flushed. Chest examination was apparently negative, both kidneys were palpable and sensitive on pressure.

First and second urine glasses were cloudy. Prostate was enlarged, sensitive, and its secretion contained pus cells. Third urine glass was very cloudy. There was a slight terminal hematuria. No gonococci were found in the urethral discharge. It was at once evident that the patient had an old urethroprostatic condition. The urine contained pus cells and some small rods that looked like splintered tubercle bacilli and were acid fast.

Cystoscopy showed trigonitis with slight edema, large eroded area near right ureter and ureteral orifice also appeared edematous. The urine from right ureter was cloudy. Left side showed clear urine. Bladder was cleared and ureters catheterized. Phthalein showed only a faint tint on right side after twenty minutes. Left side the phthalein response was normal. Urine from right kidney showed typical tubercle bacilli. The patient had a tuberculous kidney on the right side which had evidently gone untreated for some time. The important factors in this case that were overlooked were, first, history of mother dying of a pulmonary disease; second, the marked loss of weight and the facies of the patient were suggestive of tuberculosis; third, the absolutely necessary physical examination was overlooked in this case. The importance of a careful physical examination cannot be too strongly stressed in urological surgery, it simply must be done if you are going to do justice to your patient. By a thorough physical examination, I mean a general observation and examination of the patient. On questioning this patient, he stated that several smears had been made from his urethral discharge, but that a urinary examination had not been made as far as he knew. This case well illustrates the necessity of looking a little beyond the seat of the patient's

actual complaint. The coexistence of urethral disease and genitourinary tuberculosis is by no means rare.

CASE III.—Mrs. B. H., negress, aged forty-one. The patient's mother, father and one brother were living and well, sister died of a uterine condition at age of thirty-five. The patient had had measles and whooping cough in childhood. No other previous illness. She complained of pain in the lumbar region of both sides, most marked on the left, and slight burning on urination.

Patient stated that about six months previously she noticed a lumbago on the right side, and that about three months later it appeared on the left. She went to a physician who agreed with her diagnosis and treated her for lumbago during the time noted. At one time she had an attack of burning particularly at end of urination. Recently this had reappeared and had become more pronounced. She stated that the doctor once looked at her urine and said there was nothing wrong with it, except that it was a little cloudy.

The patient's general appearance was quite good, and aside from the fact that she was sensitive to pressure over the renal areas, nothing of importance was noted. The urine was acid, contained some mucous, red and white cells, colon bacilli and was cloudy. Cystoscopic examination showed a well marked trigonitis, particularly in the direction of the left ureteral orifice. Just at the lower border and in front of the left ureteral orifice there was a distinct, fingerlike papilloma which stuck up and appeared partly to occlude the orifice. Catheters passed readily into both ureters. Urine on the right side was normal. That from the left ureter contained a few pus cells and colon bacilli in pure culture. X ray pictures showed nothing. Functional tests were normal on right and slightly retarded on left. There was a pyelonephritis on the left side, caused by the obstructing papilloma. Removal of the projection with its snare and fulguration of the base cleared up the kidney lesions.

CASE IV.—Mrs. Y. D., Russian, aged thirty-six, housewife. Her mother and father were dead—causes unknown. Two sisters and one brother living and well.

The patient stated that she had never been ill until the present time. She said that about three months ago she began to urinate a little more frequently than usual and voided considerable urine. Gradually the frequency became more urgent with a decrease in volume. She had been treated by three doctors, two of whom said that they had examined her urine. The doctors all told her that she was nervous and gave her medicine for that condition. One told her that if her husband gave her a good thrashing it would probably greatly improve her condition and stop her foolishness.

Examination shows quite a well built woman of about 170 pounds, but with a decidedly worried appearance. She complained of frequency and urgency of urination, with at times dull ache in the lumbar region of both sides. The general physical examination was negative. The urine was moderately cloudy and showed numerous tubercle bacilli in the sediment, also pus cells in abundance.

Cystoscopy showed a well marked trigonitis, close to the bladder neck and tuberculous ulcers three in a row, just below left ureteral orifice. Catheterized urine from right side was practically normal. Left kidney urine showed numerous tubercle bacilli and pus cells. Phthalein was normal on the right: on the left a slight response was shown.

Diagnosis of tuberculosis of left kidney and bladder was made. This was a case where an ordinary urinary examination would have really made the diagnosis. I suspect that this was another case where the urine was looked at. Certainly if a microscopical examination had been made, the diagnosis could not have been missed. The good general appearance of the patient probably threw the physicians off their guard and caused them to blame it on the nervous system.

CASE V.—J. H., white, aged thirty-eight, United States. Family history and previous personal history negative as far as could be obtained. The patient was said to have been ill for about a week with typhoid fever. But for the past forty-eight hours had been complaining of great pain in perineum and at end of penis. Examination showed a scant purulent discharge from urethra. The prostate by rectum was greatly swollen, and during examination patient had quite an attack of pain and desire to urinate. The urine contained much pus. A prostatic abscess had ruptured into the urethra and the typhoid fever rapidly disappeared. There was nothing much beyond the prostate and patient made a prompt recovery from the acute condition.

In this patient little thought was given to the genitourinary apparatus, although the urethral discharge was still present. A simple question recalled the fact that he acquired a gonorrhea two months previously and went to a doctor who cured him in a few days.

SUMMARY

I have reported these cases because they so strongly emphasize the necessity of a careful history and physical examination of every patient who presents himself to you, particularly if it is a urological case.

They also show the necessity of a very careful examination of the urine, and how obvious cases of tuberculosis and other conditions may easily be overlooked by failure to do so. We are finding that a vast number of the lumbagoes and neuralgias of the lumbar region are either tuberculosis or other suppurative disease of the kidney or possibly stone.

We are justified in making a complete urological examination, including cystoscopy and ureteral catheterization in many of our cases of chronic backache and with prompt recognition and treatment they usually clear up. In reviewing cases one hears very frequently the expression, "My urine was looked at by my doctor," and it only too often means just that.

Kapsammer, in a lecture once said, "For chronic affections of the urinary apparatus, there is no diagnosis, no therapy without cystoscopy and without ureteral catheterization." There is much truth in those words, but a careful history, physical examination and a real uranalysis will certainly at least lead us in paths of correct diagnosis in the vast majority of cases.

229 WEST 101ST STREET.

Tuberculosis in Germany

BY S. ADOLPHUS KNOPF, M.D.
New York

One of the most gracious and dignified acts of our late regretted ex-President, Woodrow Wilson, manifested a few days before his passing away, was a promise to help the German intellectuals in their present distress. Mrs. Wilson, equally magnanimous, appealed to the men and women of America not to let the unfortunate tactlessness of the German officials, displayed at the time of her great husband's death, interfere with helping the starving children of Germany. But the intellectuals and the children of Germany are not the only sufferers in that unhappy land. According to a wireless dispatch received by *The Times* from Berlin on March 4th, fifteen million Germans are living on charity and five million are without employment. Berlin's public shelter for the homeless provides beds every night for 4,500 persons, though it nominally has accommodation for only 3,400. Of the children going to the public schools in a certain Berlin district, thirty per cent. went without breakfast and ten per cent. without a midday meal. How does this affect the tuberculosis problem in which we are all so much interested? In one Berlin district a sixth of the population had died from undernourishment, tuberculosis and allied diseases. According to Dr. Haven Emerson, who returned from there a few weeks ago, in some of the larger cities of Germany there were more deaths from tuberculosis in the first nine months of 1923 than in the entire year of 1921, and four thousand more deaths in 1922 than in 1921.

To ameliorate the condition of the undernourished masses; to come to the rescue of the suffering tuberculous patients; to help reopen the sanatoria which have had to be closed, is too stupendous a task to be undertaken by the tuberculosis workers in our country. Only such international benefactors as the Rockefeller Foundation, the Carnegie Institute, the International Red Cross, or our great millionaire philanthropists can undertake it, and the whole work should be under the guidance and leadership of such a great genius for national and international relief as Mr. Hoover.

To help the German intellectuals in general there exist a number of societies. One, known as the Relief Committee for German intellectuals and artists, was created in memory of ex-President Wilson, with former Ambassador James W. Gerard as president and Mr. Edward R. Stettinius, of New York, as treasurer. Another society is known as American Aid for German Medical Science, with Dr. Ludvig Hektoen, of Chicago, as president, and Dr. William F. Petersen, as treasurer. Still another is the Association for the Relief of Needy Physicians of Central and Eastern Europe, with Dr. William H. Welch, of Baltimore, as honorary president, Dr. Max Einhorn as president, and Mr. Henry Stenneck as treasurer. There are also a few smaller societies in New York and Philadelphia.

As far as I have been able to learn, the only two societies aiming to relieve the distress of the medical profession are the Hektoen and the Einhorn societies. Yet from reports made by American physicians who have visited Germany recently, it would seem indeed that, of all professions suffering under the unfortunate economic conditions of Germany, the medical profession seems to be the worst off. Sad and strange as it may seem, among our colleagues there the tuberculosis specialists are the most seriously stricken.

The situation has been described to me by Dr. O. Pischinger, the president of the Association of Sanatorium Physicians of Germany, as follows: The majority of private and public sanatoria have had to be closed for lack of food, coal and clothing, and the patients already undernourished had to return to their former homes. But the physicians in charge of these sanatoria lost both their homes and their means of livelihood. It does not require much imagination to realize what this homeless and jobless situation must mean to our unfortunate colleagues. Dr. Karl Heinz Blümel, the president of another society composed of tuberculosis specialists (*Gesellschaft deutscher Tuberkulose-Fürsorge-Aerzte*), described the plight of his colleagues, many of whom are so poor that they will not be able to come to their annual meeting or pay for the transactions of the contemplated reunion. Describing the absolute poverty of some of the former sanatorium physicians, Dr. Pischinger wrote me that many had to cancel their subscription to their organization's journal and that it was difficult to communicate with them. Thinking that to help the publication of the journals and to aid the physicians to come to the association's meeting would be a part of the work of the great Emergency Society for German and Austrian Science and Art, I wrote to Prof. Boas, its president, only to be notified that they are not in a position to help at this time. They are evidently in need of contributions also.

I have been fortunate enough to interest the Chicago society, of which Dr. Ludwig Hektoen is president and Dr. William F. Petersen is treasurer, in collecting and transmitting funds for the relief of the tuberculosis physicians. May I appeal herewith to my colleagues in our happy, prosperous America to do what they can? Send your contributions to Dr. William F. Petersen, 508 South Honore Street, Chicago, Ill. Prof. J. Schwalbe, Dr. O. Pischinger and Dr. Karl Heinz Blümel constitute the German committee for the distribution of the funds collected for the relief of tuberculosis physicians in Germany.

We owe to Koch the discovery of the tubercle bacillus, to Brehmer the sanatorium idea, to Dettweiler the rest cure. All three were Germans, but their disciples are in every corner of the globe and all civilized countries, except Germany, are now reaping the benefit of the work of these three pioneers. It is true, Germany was an enemy country until recently, but let us not be less magnanimous than our immortal President Wilson. "If thine enemy hunger feed him." May this appeal not be in vain.

Practical Therapeutics

INFANT FEEDING

JOHN AIKMAN, M.D.
Rochester, N. Y.

Infant feeding is probably one of the most frequent and difficult problems presented to every physician. I scarcely realized, however, how difficult it would be to cover such a large subject in a comprehensive and logical paper.

It is my object to deal only with the feeding of infants under one year of age that have for some good reason been taken from breast feeding. The reasons for and the problems of weaning, I shall not consider.

There have been so many changes in infant feeding within the past ten years that it seems wise to consider the problems in the light of present day knowledge. Infant feeding has not as yet become an exact science. It is still an art, as is the case with many other medical problems.

We have in this country at the present time, different systems of feeding in various schools. The multitude of procedures with the constant introduction of new plans and new foods, is ample proof that the present methods are not perfect. However, some of the present systems in use are excellent; but they are not perfectly simple, nor are they fool proof.

There has been an attempt on the part of many teachers to simplify infant feeding by making exact scales for feeding at different ages: stating amounts and quantities and so forth, for each age. This has also been taken up by the manufacturers of all forms of infant foods so that we are all familiar with the cards and the sliding scales which attempt to eliminate the difficult task of outlining a formula. The great mistake in these outlines from various sources is that they consider all children uniform for a certain age. While these systems are perhaps better than the old methods of former days, they fail in a large number of cases. No one system of feeding is good for all children.

In order to approach any feeding problem, it is necessary first to obtain certain information, and unless sufficient time and trouble are taken to secure this necessary information the chances for good results are poor.

In the first place a complete history of the child, from birth, must be secured. This must include the family history, home conditions, conditions at birth, the weight with gains and losses included: just what kinds and amounts of food have been given, and how they have been given. Then we must estimate the percentage of fat, carbohydrates, protein and starches furnished in the various formulas and the response of the child to these formulas: the appetite, hours fed, food between meals, condition of the bowels, vomiting and sleeping habits must also be ascertained. Of course, it is also necessary to have a history of the previous diseases, injuries or operations and a complete personal history.

After the history has been secured, the child should have a thorough physical examination. In order to give this examination, all the clothing should be removed and the child placed on a table in a good light.

It is well to have an outline to follow in order that no portion of the body will be overlooked. The best custom is to begin at the head and work down.

All this must be done because not every poorly nourished baby is thin because he has had improper food. A diagnosis of improper feeding should not be carelessly made in every case under weight. Tuberculosis and other wasting conditions must be taken into consideration and eliminated before the diagnosis is limited to socalled feeding cases.

The stools should be examined either at the time of the physical examination or as soon after as possible. The number each day and the character of the stools is important. Constipation, vomiting and other conditions should be indicated. It is a good plan to give the mother a chart on which these various points may be written. This will give the character of the stools for several days. It has been found that chemical examination of the stools is not absolutely essential in the average case. In a few difficult and obscure cases, the chemical and bacterial analysis of the stool is of distinct advantage.

With these facts, it is now necessary to correlate all information and to judge just what this particular child can best take. In considering the former foods, it is necessary to know, how much the child has taken, not how much has been offered; if the appetite has been good; and the condition of stools and the amount of vomiting present.

Through the study of the history and physical examination, we must first determine just what food we are going to give, afterward deciding the amounts, percentages, hours of feeding and other details.

It is now agreed that cow's milk is the best food for artificial feeding. But there are many grades of cow's milk. It may be dried, evaporated, malted, condensed and changed in every conceivable way.

The ideal milk for children would be a perfectly fresh raw milk from tuberculin tested cattle, obtained under perfectly sanitary conditions. This would give all the vitamines and a very low bacterial count.

Our certified milk is an attempt to reach this ideal. It has been proved that it is possible to deliver milk to the consumer on the day that it is secured. If this was done with the certified milk a better product would be delivered.

A pasteurized milk that is less than twenty-four hours old is probably the safest milk in the long run: but an honest certified milk has an advantage over the pasteurized, and would be my choice when it could be obtained. Due to the high cost of certified milk, a lack of uniformity in its freshness, and the propaganda for pasteurized milk, it seems to have lost some ground. Unless the highest qualifications are required, certified milk consumption will probably decrease in favor of the pasteurized.

The choice of milk to be used depends on several

factors. Probably the most important are the freshness and the bacterial count. The danger of stale contaminated milk is that the bacteria can easily cause gastroenteric infections. It has also been shown that the vitamine content of such milk is reduced. In order to reduce the bacterial count, pasteurization was introduced. Pasteurization of milk has markedly reduced infant mortality, and if pasteurization is not used to bolster up stale milk, the plan is an excellent one. There remain but two objections: that milk does not necessarily come from tuberculin tested cattle, and the antiscorbutic vitamines are largely destroyed. If it is impossible to secure good pasteurized milk, raw milk may be used.

Raw milk, uninspected and uncontrolled, is always a doubtful product. When there is a doubt about any milk it is safer to have it boiled. It should be remembered that boiled milk can easily become infected when allowed to stand for any length of time.

Boiled milk is sterile but has the big disadvantage that the antiscorbutic vitamines have been destroyed. However the vitamines in most feeding cases can be controlled by a proper knowledge of the existence of the possibility of scurvy and by the administration of orange juice, tomato juice or other high vitamine containing foods.

Dry milk has the advantage of being easily transported and prepared. It is asserted that the vitamines have not been destroyed. If this is true the only disadvantage is that in most cases a portion of the cream has been removed.

Evaporated unsweetened milk is of advantage in some cases but spoils easily if left in the original can.

Malted and condensed milk are both sweetened far beyond the average requirement, frequently making children gain well in weight but not securing vigor and high resistance.

In feeding children it is a mistake to aim at weight alone and disregard other points in development. If we desire well developed and vigorous children we must not overlook the possibility of rickets and scurvy.

It is well to mention frozen milk. It has been found that children are frequently upset by frozen milk and that it should be avoided if possible.

We have spoken of the vitamines in milk. The water soluble vitamine, the absence of which produces scurvy, is found in fresh human milk and cow's milk. It is destroyed by heat and by age. Whenever there is a deficiency in vitamines it is necessary to supply them by orange juice or some vitamine containing food. It should be remembered that milk formulas containing less than two per cent. of fat predispose the children to rickets, due to the deficiency of fat soluble vitamines in the food, especially under poor hygienic surroundings. This applies especially to skimmed milk, condensed milk, evaporated milk, malted milk and dried milk formulas. The use of codliver oil which is rich in fat soluble vitamines will to some extent prevent rickets. The deficiency in minerals and vitamines is made up by some pediatrists by the addition of powdered spinach and other vegetables during the sixth and to the ninth months.

There has been for many years an attempt on the part of the greater portion of the medical profession to discover some one food or modification of foods that will solve the feeding of all infants.

Some of these foods represented largely by proprietary preparations with little merit have been lauded by their manufacturers far beyond their true value.

Many of these foods are of real value in selected cases but an attempt to feed all children on any one of the foods will cause failure among those children whose digestions are not adapted to the particular food.

Numbers of our profession have at times held extreme ideas in regard to milk modification. The attempt to modify cow's milk to imitate exactly mother's milk has fallen largely into disuse. It is also well to speak here of the top milk and rich fat mixtures as advocated by Winters and others. Most of the profession have deserted this method. The other extreme of skimmed milk is now a more popular method and is used by some almost exclusively. Protein milk or eiweissmilch of Finkelstein has enjoyed a great popularity in the past twelve or more years. At first this seemed to be the food for all and is still used by some of the pediatrists of this country in nearly all of their hospital cases, especially in the presence of gastrointestinal infections.

Marriott is a great advocate of lactic acid milk. He used whole milk which has been changed by the lactic acid bacillus. This milk is diluted with fifty per cent. corn syrup. It is occasionally used with water, but he states that he has almost universally good results with the stronger mixtures.

Ladd of Boston secured good results by using olive oil, emulsified, by special process, in the place of cream of milk.

Shaw of Albany is using sour milk with curds broken up in many of his institutional cases. In the last three years several writers have reported excellent results with butterflour mixtures in feeding.

The history of infant feeding, if it teaches anything at all, will lead us to expect that any of these methods of feeding which are now affirmed by their users to be nearly perfect, will in a few years fall into more or less disfavor. They will take their places along with other methods of feeding to be used in special cases. It simply proves that no one food will ever be universally successful for all infants. Still after looking over all the old and new preparations, we are led back to fresh sweet milk on which nearly every child can be fed if the formula is properly adjusted and prepared.

Of course before the formula can be worked out, we must determine the amount of food to be taken. It is quite safe to start out with an amount somewhat less than you think the child can accommodate. If the diet is advanced slowly, we learn from experience just the amount that is best taken by the child. If too little is given, the child shows the effect of loss of fluids and is restless, cries and is irritable. If too much is given, the child refuses the last portion of the bottle and may vomit the overflow.

How often the child should be fed is a question. Today few children are put on the two hour schedule even in maternity hospitals. The tendency is to lengthen the period to three or even four hours. Advocates of four hour feeding schedules are enthu-

siastic over this method asserting that the child gets more rest, takes the food better and is less likely to vomit. The greatest argument in favor of the four hour schedule is, that it is much easier to handle in the hospital, and secures more rest for the mother at home.

At one time it was thought by Holt, Rotch and others that if cow's milk could be so modified as to have the same percentages as mother's milk then the solution of infant feeding would be found. In the hands of skilled men good results were obtained by modifying cow's milk to approximate the mother's milk. This, however, was a difficult proceeding for the average physician and in course of time another school developed that diluted cow's milk in the simplest methods possible using a half and half, two and one, three and one, and other simple mixtures of cow's milk and water.

Probably with a vast majority the simplified methods of feeding are giving better results than attempting to feed on an exact percentage basis. I am of the opinion that simplified formulas are sufficient in a large majority of cases, but that many cases are found in which this does not meet the problem. Both methods should be understood and employed to suit the particular case. The men feeding simple formulas should know approximately the percentages of fat, carbohydrate and protein that are being given. By thinking in percentages, one has a more accurate idea of just what one is doing.

There are many methods of working out modifications and each physician chooses the plan that best satisfies him.

The two following methods are simple, easy to work out and give nearly any formula desired.

CALORIC METHOD OF MILK MODIFICATION

Working out a formula from a caloric basis can be shown by the following example:

10 pounds. Weight.
50 calories per pound.

500 calories required.
120 calories supplied by one ounce of sugar.

380 calories to be supplied by milk.

This sum is divided by 20 (calories in one ounce of milk). This gives 19 ounces of milk required.

Seven feedings of five ounces are to be given (35 ounces).

35
19

16 Water required.

Formula is then as follows:

Whole milk	19 ounces.
Sugar	1 ounce.
Water	16 ounces.

PERCENTAGE METHOD OF MILK MODIFICATION

The percentage method is probably most accurately worked out by the use of 16% cream, skimmed milk and water.

Problem: 20 Ounces required of following percent

Fat	Sugar	Proteid
2	6	1

$2 \times 20 = 2.5$ ounces of 16% cream required.

16

$1 \times 20 = 6$ ounces of skimmed milk required.

3.2

We already have 2½ ounces of cream containing 3.2% proteid, so this leaves 3½ ounces of skimmed milk required.

6 ounces of milk contain sugar, $\frac{6}{20} \times 4.5 = 1.3\%$ sugar in the milk. 6 minus 1.3 gives 4.7% amount of sugar required $4.7 \times 20 = .9$ ounces of sugar required.

100

20 minus 6 (milk in formula) 14 ounces of water required.

Formula:

16% cream	2½ ounces
Skimmed milk	3½ "
Sugar	.9 "
Water	14 "

Calculations of this type always look more formidable than they really are and a little study will show that either method is fairly easy to work out. The difficult part is to know just what formula you need for the particular case, rather than how it is to be obtained.

It is obvious that exact percentages are not actually obtained outside of careful laboratories, because of the changing character of percentages in the milk from day to day. From a practical viewpoint the results are exact enough.

Working with these two methods nearly any modification of milk may be obtained. Few cases will be found where other means of modification will be needed. It is difficult to find any two methods that will give as wide a range of application.

REASONS WHY FORUMLAS ARE OFTEN UNSUCCESSFUL

Many reasons are found why our formulas do not give success. The cause that is most often given is that the child has a feeble digestion or some peculiarity. The peculiarity is most often an idiosyncrasy toward cow's milk or an inability to digest whole milk or some portion of cow's milk. An intolerance for the food may have developed by repeated attacks of indigestion, gastroenteritis, enteritis, or other conditions. Many children offer a great problem to the physicians before proper food can be determined.

There are few babies, fortunately, that are absolutely unable to take cow's milk in any form, due to protein sensitization. But there is a large group that is unable to take certain constituents of cow's milk.

Fat or cream causes more upsets in children than either protein or sugar. More children are found with fat indigestion than is generally supposed. Children able to take high percentages of fat in mother's milk often fail to take the same amount of fat in cow's milk. Fortunately for the children this is becoming well known and some physicians even advocate giving all children skimmed milk. Low fat formulas are the safest to follow, but we should not give all children skimmed milk. We should remember that children fed on low fat over a long period of time are prone to rickets.

Once fat indigestion has developed the child soon becomes intolerant towards other foods, and the indigestion is likely to prove difficult to overcome especially in the summer months.

For this reason a physician should watch most carefully the percentage of fat used and should always be on guard when using higher than two per cent. fat in very young infants. Fat indigestion is usually indicated by loss of appetite, vomiting, loose green stools and loss of weight.

The protein of cow's milk causes much less trou-
le than was formerly suspected, except in the type
f intestinal infections known as ileocolitis.

Sugar of milk itself in normal amounts rarely
auses trouble. It is only when artificial sugar is
ıtroduced that carbohydrates become a problem.

There is a tendency on the part of most physicians
) feed too high a percentage of sugar. This is due
) the anxiety on the part of the parents and of the
hysicians to have the children gain in weight and
) overcome constipation. While it is true that feed-
ıg formulas high in sugars will frequently give
reat increase in fat, it is also true that the weight
ained does not represent the best form of bodily
ssue or resistance.

Usually one ounce of sugar in a twenty-four hour
ɔrmula is sufficient. In younger children less must
e given. It is only by experience and by carefully
ying out the sugars that the proper ones can be
etermined.

GREAT CARE NEEDED IN ARTIFICIAL FEEDING

Aside from the milk and its modifications, there
:e many other reasons why formulas fail. In the
rst place, is the nurse or mother following in-
ructions?

The directions should be not only given by word
f mouth, but should be written out in full and
ɔthing left to the memory or inventive genius. The
structions must be much more simple than would
em to be actually required because in the stress
f taking care of a sick child the average mother
nds it most difficult to follow instructions.

There is no field in medicine that requires more
udy than the care of a difficult feeding case. Each
ıse should be given most careful consideration and
should be realized by the physician and the par-
ıts that considerable time may be required to secure
good result.

While the problem is difficult and exacting, good
sults can be obtained in the majority of cases.
here are few results more pleasing to see than the
turn to health of a poorly nourished child diag-
ɔsed as a feeding problem.

184 Alexander Street.

THE USE OF PROTEIN MILK IN PEDIATRICS

Arthur I. Blau, M.D.
New York

Ever since the introduction of eiweissmilch by
inkelstein, the use of some form of protein milk
digestive disturbances of infancy and early child-
ɔod is becoming more and more generalized, par-
ıcularly on the Continent. In America, its adoption
ıs been rather slow, in spite of the fact that it pos-
sses all the advantages of the commonly used bar-
y water, besides its value as a temporary food.

Protein milk is essentially a calcium caseinate,
oduced from the milk by precipitating the casein
erefrom by means of rennet or other protein
agulant, and rendered soluble by neutralization
ith calcium hydroxide and subsequent evaporation
dryness. It has all the advantages of Finkel-
stein's eiweissmilch, with the added advantage of practicability and simplicity of preparation, requiring as it does only milk and water, or only water in its preparation. It is quite stable, keeping well for about six months, and longer, on ice. There are several brands of protein milk on the market.

The benefits derived from the use of protein milk are due to its high protein and low fat and sugar content, and the presence, in some, of lactic acid organisms. The percentage composition of the various protein milk preparations are similar to Finkelstein's eiweissmilch, the analysis of which is: Protein, three per cent.; fat, 2.5 per cent.; carbohydrates, 1.5 per cent; salts, 0.5 per cent. The high protein content favors intestinal digestion, because of its tendency towards intestinal alkalinization. In addition, the alkalinity produced counteracts the acid bacterial fermentation. The calcium present facilitates the formation of lime soap stools. The lactic acid organisms are also antagonistic to the acid bacterial action.

Protein milk, however, is not a permanent food, and while its use is beneficial for the period of the disturbance, it is not to be continued longer than necessary, usually no more than five or six weeks at the longest. Since its food value is but small, having a caloric value of only about twelve calories to the ounce, some form of carbohydrate should be added as soon as feasible. It is a dangerous procedure to continue the protein milk more than one or two days, without the addition of some sugar, for while the intestinal symptoms may improve under its use, the harm done to the nutritional status of the child, would more than overbalance the benefit upon symptoms. At first, one per cent. sugar is to be added and gradually increased up to five per cent., making a total sugar content of about seven per cent. The higher sugar percentages, however, are only required with the prolonged use of the protein milk. The most desirable sugar is dextrimaltose, because of all the sugars maltose is least apt to ferment. In some cases cane sugar can be used, up to about two per cent., but not lactose.

The percentage of fat in the protein milk depends upon the quality of the milk used in its preparation. If a lower fat content is desired, skimmed milk or buttermilk may be used in part, or instead of the milk. The use of buttermilk is particularly advisable in some cases, where a stronger lactic acid bacterial content is desired. This is indicated in dystrophic and atrophic nutritional conditions, with small intestinal diarrhea.

Protein milk is indicated in all fermentative diarrheas with green, sour, acid, and loose stools, with or without mucus, where the fermentation is due to carbohydrates. It is also beneficial in infectious diarrheas, where the dyspepsia is secondary to some infection outside the alimentary canal. Dyspepsia due to fats and diarrheas of mixed types are also favorably affected by protein milk.

CONCLUSION

Protein milk is indicated wherever there is a favorable medium in the intestinal canal for the work of acid producing bacteria, as is found in fermentative diarrheas.

Historical Medicine

Medicine and Philosophy in Virgil

JONATHAN WRIGHT, M.D.,
Pleasantville, N. Y.

(*Concluded from page 312*)

I was once much interested in this journal (14) to draw attention to the connotations the word *purge* still has—how the African mother could see no reason why she should not purge her son of heresy by means of rhubarb and jalap. Virgil was no doctor and he did not pretend to say what was the change wrought in the mystic aura of the soul or of the body in Hades, but it had to be accomplished before entering Elysium and when that day finally came the purified changed their abode and after a thousand years they were again embodied in fresh generations of mortal men. Surely the lines can have no other meaning as to the persistence of disease after death, for when this comes:

> non tamen omne malum miseris nec funditus omnes
> corporeae excedunt pestes, penitusque necesse est
> multa diu concreta modis inolescere miris. (5)

Except for this and the metempsychosis, one can not but be struck by the similarity of the belief of Mediaeval Christianity with the report Anchises made as to the fate of immortal souls. The persistence of disease after death goes back as a belief I do not know how far, but much further in Greco-Roman theology than in Virgil. Euripides (17) makes Hecuba say while she is winding roller bandages around the gaping wounds of the bruised body of poor little Astyanax: "Thy father (Hector in Hades) will attend to these for thee."

Virgil busied himself with the chemistry of the soil in his early poetry, recording doubtless the practise of the model farmers of the great latifundia of the day, but to this I have referred elsewhere (15). Closewoven baskets and corn sieves were his soil filters. "With a stout pole take them down from the smoky rafters of the peasant's cabin and come to the fields with me and I will show you how to test the soil," he said, but he invites us also to the cattle pens and pastures where he promises to teach us the causes and the symptoms of disease in the flocks. The "scab" attacks the sheep because of the cold rain. The ice gets into their coats and when these are soaked through later the sweat and the dirt against the hide irritates it and sharp thorns tear it. The shepherd washes the fleece and makes application of an ointment of oxide of silver and sulphur and pine tar, squills, hellebore and black bitumen, but the result is no better than if one takes a knife and cuts out the ulcer to its furthermost ramifications, for the trouble thrives and is nourished when protected, but the shepherds refuse to let the doctors put their hands to the sore and rest their hopes of cure on the gods. When it gets very bad, however, and the animal has high fever, to subdue it blood must be drawn from the vein at the bottom of the foot. Praying to the gods, slashing a sick beast's foot or pouring turpentine in the hole left by a jagged nail, or splitting a cow's tail and rubbing sa in it for the colic, or all that goes under that name wit modern shepherds and cowherds and primitive hors doctors, is no improvement on treating the "scab with scabs made of muck, but Virgil we see turn to the knife. On the whole it is not a bad pictur of the farmer doctoring of my day for sick beast How much better the knife is for such parasitic di ease is doubtful, but does it not bid us pause an think a moment of the long ages during which wh seems such aimless therapy for man and beast ha ruled the world? Think of the countless myriad of socalled rational beings who have believed in an practised such therapy and ponder if we, mere in sects of a day in the abyss of time, are likely to hav wiped it all out and put something which is th true truth in its place.

Primitive man's first instinct is to hide diseas to cover it up. When he falls too ill himself t stand up and fight for his life, like a dog it is his in stinct to crawl into hiding and die or if he recover in his inmost soul, whatever has been done for hi it is the gods he thanks and he is probably not far o the trail. He began to hide ulcers under a plast as a sort of atavistic instinct, but we have to trav further into the story of the beliefs of primiti man than I can undertake to do here to get a hi of why he first began torture as a method of trea ment, burning, blistering, bleeding, scarifying—an I am encroaching on the memories of practise o some still living. It is a long ghastly record, th torturing of the sick in the name of science, an Virgil was skirting the truth when he intimates th kind of shepherd doctoring he describes was derive from desert dwellers, who feasted on curdled mi mixed with horses' blood; but he prefers the kni to all herb doctoring:

> . . . siquis ferro potuit rescindere summum
> ulceris os. (6)
> . . . carry the knife clear to the end of the sinus.

There are other ills of cattle, more serious by fa and these were contagia you must shun by keepi your flock far from contact with infected herds. Th symptoms were described with a realism as to ge eral phenomena, which is so striking it would sure to arrest the attention of any young farmer lad, if, miraculously, any such read the text Virgil. Seneca declared (12) Virgil had no desi to instruct the farmer, but wished to please h readers and it at least attracts the attention of th reader who can recognize the merits of the muses not the symptoms of the diseases of the beasts of t field. For the eye of the farmer's lad, who m have turned to doctoring his own kine by the tu this meets it, we may paraphrase Virgil's text, ro bing it of its magic therby. When you see one the cattle far out in the field, lying down more oft

the cool shade of the trees or following last be-
nd its comrades, nipping listlessly the tops of the
asses as it passes or, as it lies down, reaching out
graze and coming belated in at night, stop the
il at once with the sword before the dread con-
gion spreads in the heedless herd. Many of these
ttle plagues sweep through the country side like
whirlwind over the sea, seizing not upon here and
ere a few in the herd, but suddenly in the summer's
eat it wipes out the shepherd's hope, not of gain
one, but of livelihood, for all the race of kine
erishes thereabouts. Among the Noric Alps from
e shelters on the hilltops one can see the shep-
erds' walks and the woodland glades far and wide
eserted. Wild animals as well as the tame lie dead
the pools, water as well as the food is tainted.
vidently such disasters were as calamitous to a
untry side of peasants as war or a pest among
en. Besides frantic appeals to the gods and fre-
uent immolation of victims, they slaughtered the
ck animal as soon as the disease was manifest in
, at least Virgil considers this
e wise thing to do. The
octor's art is of no avail. The
entaur Chiron and Melampus,
ho is famous for having
ured the madness of the
rgive women, themselves re-
red baffled from such a call
pon their skill. The despair-
ng farmers, with death and
uin staring them in the face
an find no sale even for the
ides. Anthrax?

Fig. 2.—From the Pictura Ornamenta Codicis Vaticani Vergilii.

Primitive pantheism is the
orm of mysticism we have
ound in the youthful Virgil
hose boyish poem on the gnat
r mosquito has transcendent
erits, but bears the unmistak-
ble earmarks of youth. At
he crushing of the insect he
eflects that it, too, has a share
a God's universal scheme. It, too, has a soul,
hich is its connecting link with nature and he
akes the shepherd pay a tribute to it in lines
have quoted above. The homilies handed out to
he young have always had a phase of this. Go to
he bee, thou sluggard, the busy bee, whose industry
hou shouldst imitate and whose labors result in
narvels of God's care for the lowliest of His crea-
ures, He, who marks the fall of the sparrow.
hat is the spirit of the Culex and one might think
he Christian Fathers could have found in this that
ffiliation with their faith which made Virgil a sym-
athetic figure of a pagan past, but that was not the
train of piety which distinguished the early church.
t was one entirely too anthropocentric to feel deep
n its spirit that brotherhood with all living things
hich has entered into modern Christian concepts,
erhaps in some mysterious way from modern con-
act with oriental civilizations, but which so per-
neated the pagan beliefs of antiquity. Virgil, too,
lrew his homily from the bees in one of the Geor-
ics (6). I will not pause to show how erroneous
ere some of his ideas as to the biology of bees, but
hasten to the lines which fill out the budding
thought the boy exhibited in the Culex and which more clearly than any I know express that strain in pagan belief which is finding its echo in the modern humanitarian spirit.

> Nunc age, naturas apibus quas Jupiter ipse
> addidit, expediam, pro qua mercede canoros
> curetum sonitus crepitantiaque aera secutae
> Dictaeo caeli regem pavere sub antro. (7)

The King of Heaven himself in the Cretan cave had had reason to mark the highly organized city state of the bee and the brotherhood which antiquity felt with all living things lies at the bottom of much trouble for us in some of its extravagant modern manifestations. The antivivisection movement is anathema to modern science, but it seems to me that modern science, at least modern scientific medicine, does not comprehend the springs of this movement are so deep grounded as they are in the philosophy of past ages as well as in the encroaching religious beliefs of modern times. These are receiving constantly stimuli in western lands from oriental sources. The sooner modern science comes to realize it is up against one of the greatest and most powerful tenets that have ever swayed the minds of mankind and that it behooves it in its own interest to become acquainted with its history the sooner it will arrive at some compromise which is inevitable in the long run. If too long deferred the very foundations of anatomical and physiological science will be shattered. Legislation in the old world as in the new is but the field on which this ominous deeplying thought of mankind is being exhibited. Deference must be paid to this sentiment as it is one of the cosmic forces which are too great to resist, however destructive we may think they are to our interests in biological science. The development of a spirit of compromise will save a world of trouble, perhaps disaster.

Virgil in magnificent verse lays this mighty force in pantheistic philosophy before us and let no medical man think it is foreign to his interest as a member of a profession whose highest boast today is that it is becoming scientific. "They say there is in the bees a portion of the divine mind and a breath of its ætherial presence, for God permeates all things, the stretches of the land, the vast expanse of the ocean and the depths of Heaven itself. In all this are embraced men and herds of cattle, all manner of wild beasts as well, all on birth have their feeble lives protected" (8). When modern humanitarianism, let us not call it sentimentalism, arrives at the point of musing tenderly over the crushing of a mosquito, "parve Culex," it is going to be hard sledding for some of the activities of biological science. The revival of mysticism if it tends toward this growth has more than a passing interest for us. It was a long flight, in Virgil's artistic evolution, from smash-

ing the "parve Culex" to the tragic crushing out of the life of Dido. It is singular how people will strain at a gnat and swallow a camel, how tender hearted ladies will kiss their lords goodbye on the way to filling little rabbits and the feathered tribe full of shot, and shudder with horror at the inoculation of a guineapig and usually refuse to consider kissing the man of science. They will read unmoved the headlines of horrid misery in the track of the plague and then start expensive farms for the support of decrepit dogs and cats and horses. But we have no time to point out the inconsistencies of human nature. They have been noted before. The practical thing for us to do is to exercise more tact and more real supervision over the aspirations of the scientific youth ready to wade in the blood of his fellow creatures, regardless of their pain, through scenes calculated to shock the sensibilities of modern pantheists. The fact that Virgil's shepherd carried out the funeral obsequies for a murdered mosquito and that Æneas did not wait to see Dido's soul fly up to the winds, *"atque in ventos recessit"* (3), with the smoke of the pyre on which she died for love of kisses from him, is a joke we can regale one another with, but it has nothing in it calculated to move the ladies of the Society for the Prevention of Cruelty to Animals in our favor.

It was a long flight from the Culex to the Æneid for Virgil, but whether in boyhood or in the splendor of his mature years we may easily find traces of the philosophy of his day, not the all pervading pantheism alone, but the doctrine of the pneuma which was in a way a corollary of it. Dido's soul went back to the winds at the end of the fourth Æneid just as in the fourth Georgic the pneuma may be found as the efficient agent of the pantheistic scheme of the phenomena of the bees, and it is in the winds that blow the shepherd hears the plaintive tale of the wandering soul of the Culex. In Homer we read of the horses of Achilles and one of them was sired by the North Wind, which, although it may be solely a trope for his swiftness, partakes much more of realism in Homer than it would in the lines of his degenerate successors of our own day. It has not been difficult to collect evidence of the all pervading doctrine of the pneuma in many other passages of the Iliad (13) and we may plausibly take it that it was literally meant, when we become aware of certain passages in Aristotle and Virgil. For the inference receives direct support in the verse of the latter. Indeed this is quite evidently one of the passages in which he had in mind incidents of the Iliad, which he remodelled after his own fashion. Aristotle had given credit to the popular belief that a pheasant hen was sometimes impregnated by the wind blowing on her. Lucretius, to whom Virgil owes much both as to his philosophy and his art and to whose great work he was devoted in his youth, refers (17) first to the humoral doctrine when he says some liken the nature of the soul to that of the blood but some, if you choose liken it to the wind.

> et se scire animae naturam sanguinis esse
> aut etiam venti, si fert ita forte voluntas.

All sorts of such beliefs have been found among modern primitive tribes, a leaf falling on the abdomen, a stone or a fish in some way producing the state of pregnancy by its presence—all of them relics of the time when the real cause of impregnation was unsuspected. In the Georgics, hearkening back doubtless to Homer the poet says the mares, when in heat, ranging the rocky pastures near Thebes, from whose genital secretions love filters were made, standing on the lofty peaks and facing the wind become pregnant without receiving the attentions of the stallion:

> . . . . . illae
> ore omnes versae in zephyrum stant rupibus altis
> exceptantque levis auras et saepe sine ullis
> conjugiis vento gravidae (mirabile dictu). (9)

However, the peasants whom Virgil knew put no such chimerical expectations into the practical conduct of life for they fed the sires of their herds that their offspring might not lack vigor, but the females of the flocks at the breeding season they kept fasting and like our poultry breeders today gave them exercise to the point of fatigue to increase their fertility and lower the mortality of parturition. For when Venus languishes in laziness and luxury from lack of exercise the seed falls on barren ground, thus recognizing obesity as associated with the sterility of the female (10).

The author's references will appear in his reprints.

Contributors to the Science of Medicine

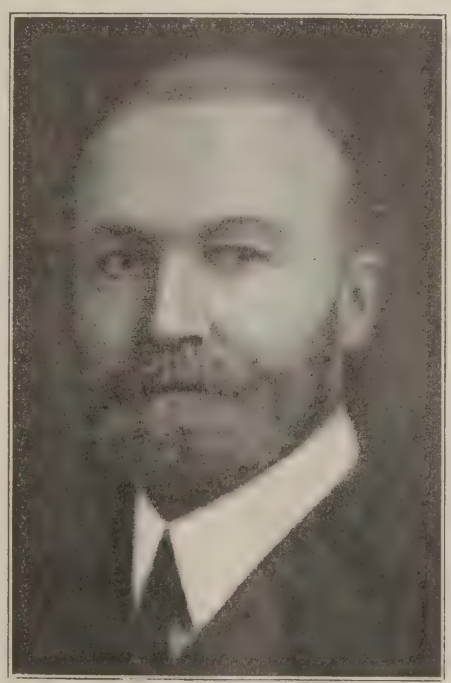
JOHN BENJAMIN MURPHY, M.D.,

"Doctor Murphy," writes Dr. William J. Mayo in a biographical sketch of the great physician, "is the surgical genius of our generation." Murphy's successful medical career, the many prominent positions that he held, both as teacher and as physician, and the numerous honors heaped upon him in this country and abroad, bear witness to this high place in the science and art of medicine.

Murphy was born of Irish Catholic parents in 1857 at Appleton, Wis. He received his elementary education in the public schools of his home town, and his medical education at Rush Medical College, with two years of postgraduate study at Vienna. Ability as a teacher was probably Murphy's most prominent and distinguishing characteristic, but he also attracted universal attention among surgeons by his invention of the well known Murphy button, recorded in a classical article in the *Medical Record*, 1892, and his latter years were notable for his work on deformities due to infections of the bones and joints. His writings on surgery of the lungs and of the nervous system have also received universal

ecognition. His wife, who was Jeannette Plamonlon, of Chicago, was his constant helpmate and inspiration throughout his career, and often acted as his chief laboratory assistant. The John Benjamin Murphy Memorial Hall of the American College of Surgeons in Chicago stands as a perpetual reminder of the classical nature of Murphy's work, the honor in which he was held by the members of his profession, and the inspiration of his teaching.

Murphy has been compared in the impression he made upon his audiences, to Lincoln. The tall, gaunt frame and the harsh, meagre, strident voice were the same. The most striking difference lay in the fact that Murphy was one of the handsomest men of his day, while Lincoln was exceedingly plain. Murphy had no such command of language as Lincoln, but both had the faculty of deeply impressing their hearers—"when they spoke they seemed to be delivering a message charged with truth and pregnant with confidence and hope," writes Sir Berkeley Moynihan. This power of complete selfexpression seemed to come, in the case of Murphy, from his burning and quenchless enthusiasm for life in all its manifold activities. His attitude toward life, however, was grave, serious; he was always much in earnest. Except to a very few, he was not responsive nor genial as a friend; hence he was admired and respected by those who knew him, rather than loved. His work was so obviously brilliant and his position in his profession so secure that he had the rare experience of never being even touched by jealousy except in the earliest years of his career. A strange thing was that Murphy, with all his personal magnetism and brilliant work, never trained a worthy successor—never left a disciple to carry on his enthusiasm, his glow of life, his fervor and devotion to his work.



JOHN B. MURPHY

All his activities, both of mind and of body, were characterized by an extreme orderliness. He worked always with a clean desk before him. His method of presentation was without exception the same: a wide survey of the subject to be discussed, made interesting by the magic of his personality and conception of it; disclosure of the gaps in our knowledge of the subject; suggestions as to the means by which that knowledge or a want in our technical methods could be made good; a record of experiments to elucidate or solve a difficult point; a wealth of clinical observations and a formidable array of arguments, leading to an inevitable conclusion stated in terms easily comprehensible to all. His mind was always orderly, eager for new truths, and expectant of them. He was an adept in making classifications simple and easily remembered of the most apparently complex subjects. All his efforts were worthily expended—he never wasted his brilliant energies on hack work nor on things that could be equally well done by others. Yet throughout his whole life he overworked. He might have lived ten years longer, had he not spent himself so lavishly. But he had only one speed for work, and that the highest that his great energy could command. One of his frequent remarks was, "I do not wish to linger after my work is done." Yet all who knew him felt that medical science would have received many more contributions from so brilliant a mind and personality had death not claimed him in his sixtieth year.

Sir Berkeley Moynihan, in his brilliant memorial address on Murphy published in *Surgery, Gynecology and Obstetrics,* says of the great surgeon in his clinics: "As he began to speak, one felt a strange sense of disappointment, even of dismay. For, while the handsome face and upright figure were things of real beauty, the voice in which he began to speak was quite unpleasant. It was harsh, even raucous, shrill, apt to wander into other keys. . . . But as he continued speaking, the voice gradually ceased to distract; it became smoother, quieter, and more evenly pitched, and all thought of it was now lost in rapt attention to the matter. For things were happening. . . . The whole intellectual mechanism underlying a great subject was being shown both in detail, and in all the majesty of moving parts. . . . And then Murphy would operate. . . . He was of the true faith. He believed in safe and thorough work rather than in spacious and hazardous brilliance. He was infinitely careful in preparation, and compared with many was inclined to be slow; but every step in every operation which I ever saw him do was completed deliberately, accurately, once for all. It led inevitably to the next step, without pause, without haste; that step completed, another followed. . . . And so when the end came, a review of the operation showed no false move, no part left incomplete, no chance of disaster; all was honest, safe, and simple; it was modest rather than brilliant. During the whole operation, Murphy talked; not wasting time, but expressing and explaining aloud the quiet, gentle, dextrous movements of his hands and purposeful working of his mind." When the operation was over he would draw his stool near to the front row of seats, cross his legs, and talk as only he was able to talk—of surgery in general, of the case in particular, of his own faults and shortcomings, of special experiments made to elucidate, and of doubtful issues. His talk was now quiet; the fervor and passion of the operation gone. Absolute truthfulness was the dominant expression of Murphy's personality. Like Lincoln, to quote Moynihan again, "he never looked at truth askance or strangely."

Editorial Articles

INSECTS AND THE DECLINE OF NATIONS

During recent years a great deal has been learned of the rôle of insects in the transmission of disease and it has been suggested more than once that the disease bearing insect has played a sinister part in the decline of nations. Malaria conveyed by mosquitoes has been given as a cause, perhaps the chief cause, of the fall of the Roman empire, as well as of the Greek republics. Sir Ronald Ross, himself the discoverer of the manner by which malaria was conveyed by a particular kind of mosquito, was the first to advance this theory several years ago. In the heyday of their greatness malaria was unknown in Greece and Rome; if it had been prevalent descriptions of it would have been handed down. The malaria bearing mosquito might have lived amongst them but as she was not the host of the parasite was harmless. It was the very successes and military power of Greece and Rome especially that brought about their fall. Expeditions into tropical countries yielded great booty but they also introduced malaria by means of the malaria infected soldiers and captives. If anopheles were present, as doubtless they were present, the disease would spread as forest fire because the soil was virgin.

There are few diseases which sap the vitality as does malaria, and according to Ross this was the cause of the decadence of Greece and Rome. Macedonia, which was abundantly fruitful in the days of Greece's prosperity, is now almost a waste land and reeking with malaria, as soldiers who served there during the war know to their cost. The Roman Campagna which was as flourishing and fruitful as Macedonia has been rendered desolate by the same insidious means. That malaria there is transmitted by mosquitoes has been proved beyond doubt. While malaria is the disease which, on account of its prevalence and devastating properties, is the most conspicuous of the insect borne diseases, there are many others which carry and transmit disease far and wide. Plague, sleeping sickness, yellow fever to wit and insects are under suspicion of being directly concerned in the transmission of other dangerous maladies. In fact, there is the closest relationship between entomology and hygiene. If the Greeks and Romans had known of the mode by which malaria is spread, it may be imagined that they would have saved their civilizations by destroying the insects. And yet their descendants, although they know, do not practice the only really effective methods of ridding a country of malaria. Instead of attempting to treat and immunize the dwellers in the Campagna by the systematic administration of quinine, the manner of procedure of the Italian physicians, it would be far wiser to take a leaf from Ross's book and drain the swamps, destroying the breeding places and abolishing mosquitoes, and with them malaria. Wherever this plan has been carried out efficiently it has been entirely successful.

The menace of insects as conveyers of disease is beginning to be realized, even when they are not infected they carry germs and dirt on their feet as the common fly carries them. The crusade here against Musca domestica has been a noteworthy forward hygienic movement and has been followed by excellent results. Rome and Greece probably declined through lack of special entomological knowledge and it might be well if all modern nations put this knowledge into practice. In certain parts of the country malaria is prevalent, swamps are numerous and mosquitoes abound. If these breeding places were drained, not only would malaria vanish, but new country for cultivation would be opened if not for this generation, for future generations. The initial cost might be great but in the end it would return exorbitant interest in health and prosperity.

THE SPECIALIST

There is much talk, which comes also now and again to the surface in print, of the evils becoming apparent in our intellectual life as a civilization due to the narrowing specialization of science and especially of medical science. Much of this criticism is void of any constructive suggestion. Educators tell us there is no more room for the introduction of liberalizing influences into medical education. Earnest workers tell us there is no time for the cultivation of those arts which broaden and humanize the intellectual life of men of science. This is heard most acutely and most insistently in medicine.

If we seek a solution for the evils of specialism in the intellectual life of modern civilization and for a moment contemplate the possibility and the desirability of checking it, we realize the necessity of caution, lest we enter a blind alley, lest we take the wrong path to a constructive idealism. We do not need less specialization, we need more of it. We need to so limit the day's work that hours of leisure are possible for a higher culture is the scheme advocated for the working man by advanced sociologists. We have cleared away the saloon in a sort

dumb instinctive wisdom as a precaution and the scheme for a better and happier social life has been launched for those who work with their hands.

But as yet no one has urged the same doctrine as the proper ideal to strive for in the problem of the alarming lack of intelligence manifest in the working man laboring in the specializations of science. To appropriate and strip of its pristine meaning an axiom of diplomacy, *divide et impera.* Put two men instead of one at the laboratory table where a biological problem, involving physicochemical research is being worked out and let each be more free to seek the rudiments of general intelligence. Of course the solution is not so crude as this, but the suggestion is sufficiently obvious. As a matter of fact modern specialism is suffering from the discomforts of infantile dentition, not from adult marasmus. Modern research is still a mere baby and while there is well justified alarm that it may get lost in the woods,

> Questa selva selvaggia ed aspra e forte
> Che nel pensier rinnova la paura,

in the entangled jungle of which Dante sung, penetrated by no beams of light from the outside after all modern specialism will grow up, it is to be hoped with some confidence, into a more intelligent and sympathetic manhood than certain dismal observers of its childhood seem disposed to prophesy.

INFANT WELFARE

No steps in the province of preventive medicine are of greater importance than the welfare of infants. A large proportion of infants die during the first year of life, a proportion much larger than should be the case, while many of those who survive are ill nourished and weak. Both the high rate of mortality and the wide incidence of malnutrition are due largely to errors in feeding. In all countries it seems that breast feeding is being practised to a less extent with, of course, correspondingly bad effects. Recently, according to the Paris correspondent of the *Medical Press and Circular,* February 20th, last, the welfare of infants has occupied the attention of the French Academy of Medicine. Professor Wallich stated that in 1921, out of 83,000 babies who were confided to the care of wet nurses or handed over to the *assistance publique,* 5,000 only were breast fed. Bottle feeding, which in 1913 was employed in only seventy-eight per cent. of children, attained to ninety-three per cent. in 1920. In the Department of the Seine ninety-eight per cent. of children are bottle fed. Professor Wallich is strongly in favor of municipal *crèches or poupounères,* where babies can be reared under strict medical supervision.

The French Academy of Medicine has also passed resolutions with regard to the status of midwives. At one time, and that only a few years ago, the professional standing and social status of midwives in France were equally low. They were somewhat of the same class as the monthly nurse immortalized by Dickens as Sairy Gamp. During the past few years there has been some improvement in both respects but there is room for considerable more. The academy desires to raise the standard of general education as well as of professional competence. With this end in view it is suggested that midwives should hold a certificate to show that they possess a fairly good general education. Moreover, that at stated intervals, after qualifying as midwives, they should attend some official obstetrical clinic for a period of ten to fifteen days. The question of infant welfare is bound up to a considerable extent with that of antenatal care and skilful midwifery, and thus it is of the first consequence that midwives should be competent. Pregnant women are being taught now how to care for themselves, or at least are afforded opportunities for such instruction, and it is impressed upon them that antenatal care is an important part of the teaching of infant welfare. But the teaching of midwifery still leaves something lacking. As great care and skill are needed in obstetrical technic as in any other surgical operation and it should be performed under favorable conditions. The point was brought out and strongly stressed in a report published by the British Ministry of Health a short time ago and measures were suggested for rendering antenatal care and the technic of midwifery effective. It was pointed out that the teaching in this branch of surgery which the medical student receives when at hospital is not nearly thorough enough, in fact, is frequently almost futile. And this is no doubt the case, to some extent, in America.

On February 7th, last, one of the foremost British authorities, Mr. H. Beckwith Whitehouse, M.S., of Birmingham, gave an address before the Ulster Medical Society in Belfast on puerperal sepsis. He stated that the occurrence of puerperal sepsis and other accidents of midwifery were largely the result of ignorance on the part of the midwife. In advocating the inspection of all hospitals and homes where midwifery was conducted Mr. Whitehouse stated that this would be welcomed by all reputable homes, and that it would put a stop to many socalled homes which were little better than private houses. The low incidence of morbidity in large hospitals as the Rotunda in Dublin was quoted. He was of the opinion that midwifery and general practice did not easily assimilate, and that the general practitioner would probably be glad to get the responsibility off

his hands and he advocated the formation of district groups in which one practitioner would do all the work in obstetrics.

In the care and management of the infant there are three periods during which skill and practical knowledge are especially required antenatal, midwifery, and during the first year of life. With regard to midwifery it seems to be the growing opinion that neither students nor midwives are instructed in a sufficiently thorough manner in the technic of obstetrics and it is in the interests of all that midwifery should be done by one skilled in the technic. And, this is of even as great importance, that the environment during midwifery should be as aseptic as possible and therefore should be done, except in particularly favorable circumstances, in hospitals equipped for the purpose. Lastly, that during the first year of life infants should be fed at the breast unless there are really sound reasons for contraindicating this natural procedure. To carry out such a scheme, it is predicated that women shall be taught antenatal care, that medical students and midwives shall be thoroughly instructed in all matters pertaining to obstetrics, that everywhere hospitals shall be provided for the reception of midwifery cases, and that a campaign of education be launched for the purpose of impressing upon women the necessity of breast feeding and managing the infant during the first year of life.

A NEW CLINIC

The suppression of bad habits and the encouragement of new ones is the foundation of all education and has been accepted and put into practice in a more or less desultory fashion in connection with physical education in schools. Such school work, while invaluable, comes some five or six years late, and, hence, hardly is comparable with habit formation in mental studies.

Some attempt at changing habits is carried on in the practices of most physicians, for "go and sin no more" (along the line of sinning for which the patient applies for aid) is uttered or implied in all good medical advice. Again, however, the instruction may be late for the formation of healthier habits. The most appropriate time for efforts at making healthy living spontaneous comes in infancy and earlier childhood. It must here come, however, through the guidance of parent or nurse, but with such help it is amazing what can be accomplished.

Every clinic is, to some extent, a habit clinic. It is usually a bad habit that takes man, woman, or child, to a clinic. Every children's clinic has become more and more deserving of the name because habits are being more and more examined into. Now the name itself has been adopted, and we have, if not a new clinic, at least a clinic with a new name—the Habit Clinic. This originated, we believe, down east,—at any rate they are being established throughout the state of Massachusetts. The function of these clinics is to study and treat undesirable habits and personality defects in children of preschool age, and might possibly be more specifically called Bad Habit Clinics, but their object is, of course, to establish good habits.

The clinic is, as we have suggested, not new, but there is something more revolutionary in the name than may seem at first glance, for we have got away, in terms at least, from anything that smacks of medicine in the older and narrower sense.

We wish that there might be other changes of nomenclature in line with this. In particular there comes to mind the use of the word school nurse. The word nurse always suggests sickness and the sickroom. We might do worse if we used the term "school health worker." When the nurse had for her work the treatment of skin diseases in schools, she might well have deserved the name which still clings, but as that work is, or should be, relegated to the home, it is hardly appropriate to call her a nurse. Also in school work the words "physical examination" might well be substituted for the phrase "medical examination of school children."

All the world seems to be a clinic nowadays, and there are doctors galore for mind and body. It might help a little, however, to let the sickness side of the clinic fade apace and give it more the atmosphere of positive health. A habit clinic is a step on the way to what may before long be called a health clinic. Maybe some day we shall even graduate doctors of hygiene instead of, or as well as, doctors of medicine. The doctor of public health is, of course, a pioneer figure in the new highway to health.

COMMON COLDS

That common colds and associated infections are among the chief sources of loss of time in large business and industrial establishments has been shown in a study made recently by the Metropolitan Life Insurance Company. This study revealed that these disabling affections occurred at a rate of 420.7 per 1,000 employees for the year. The average days of disability for this illness per person on the payroll for the year was 0.9, and the average days per case were 2.2. In all, there were 6,233 days lost in the year from these conditions, which included head colds, acute bronchitis and tracheitis.

It was found that these infections of the upper respiratory tract have two periods of maximum incidence: the first, following the advent of cold

weather in the late summer and early autumn; the second, occurring during the following January or February, when the coldest weather of the winter is likely to prevail. The data showed also a distinct relationship between respiratory infections and changes in the weather. It was found that the number of common colds varies with the rise and fall of the weekly mean temperature. A drop of ten degrees carried with it an increase of eighteen colds a week in the group studied, consisting of 6,770 people. However, other weather elements, such as mean relative humidity and total precipitation seem to have only a slight influence upon this incidence.

"We are confronted with two important factors," the report goes on to say, "in connection with the prevention of the infections of the respiratory tract. There is, first, the annual downward swing of temperature, and, second, the possible relationship of the minor infections which arise in the fall and early winter to those occurring later on." The first, or ecological factor, can be compensated to a degree by proper ventilation, clothing, and heating of buildings and transportation facilities. The second factor requires further study, perhaps leading to important preventive measures.

TEACHING BY FICTION

One of the contradictions of the the human mind is its willingness to accept as truth almost any kind of fiction and its rebellious antagonism to any dose of truth, no matter how minute its size. Truth must be coated with the sugar of fiction to gain any widespread acceptance. *The Man Without a Country* has made more converts to patriotism than the ringing truths of the Declaration of Independence and in its day *Slovenly Peter* made more faces shine than the nurses teaching that "it is better to be clean than to be happy."

All of this by way of saying that the fiction route is the easiest approach to the average intellect and to urge the more general adoption of this avenue of attack by social hygienists. The *Nation's Health* for September last contains a notable example of what may be done in this way. Rucker, who by the way wrote *The Sword of Damocles,* one of the earliest and most successful antivenereal fiction preachments, in *The Fourth Man* strikes from another angle. He tells the tragedy of the wife of the philanderer. A bishop, a judge and two business men engage in conversation about the death of the wife of one of their acquaintances, a popular, hale fellow of the too well met type. It develops that he probably infected his wife, thereby causing her death. The fourth man asserts that it was murder or at least manslaughter and in the argument which follows, drags the lapses from virtue of the other business men, the judge and himself out into the light with almost malicious insistence and startling consequences. The psychology of the bishop and the judge is truth itself and the sequence of the story is accurate.

There is a mighty lesson in this short virile story and the barb of the parable is driven home and clinched in the mind of the reader in no uncertain manner. Its similitude of actuality is so perfect that it conveys the impression of absolute truth, yet it must be fiction pure and simple, since probably no group of men could ever be forced to make such pitilessly honest confessions.

This is a type of public health teaching which is to be commended and more generally employed and it is to be hoped that *The Nation's Health* and the author will follow up this very profitable and worthwhile method. After all, the way to teach humans is to be human.

CHILD WELFARE

Among the problems of child welfare dealt with at the meeting of the International Association for the Promotion of Child Welfare, held in Geneva last July, were the repatriation of juvenile delinquents, the establishment of infant rearing centres, improvement of day nurseries, and school hygiene. The convention for the repatriation of destitute or juvenile delinquents provided in its draft for the repatriation of minors of foreign nationality by the contracting States, especially of those minors without means of protection or support, and escaped delinquents, who had been removed from the authority of their parents or guardians. The minor must be handed over by virtue of a decision given by the authorities of his native State.

The following is a summary of the recommendations passed at the meeting in regard to the three other subjects:

Infant rearing centres: It was recommended that, because of the difficulty of supervising the care of infants placed out promiscuously, rearing centres be established under the direction of qualified medical officers.

Improvement of day nurseries: 1. All crèches should be under the direction of a physician. 2. Separate rooms should be used for the cradles, the linen, disinfecting purposes, and isolation of patients. 3. They should be open to the pupils of puericulture schools.

School hygiene: Close cooperation should exist among the teacher, the school physician and the school nurse. The teacher should be acquainted with the fundamental principles of hygiene. Each child should be submitted to an annual examination, of which a record should be kept, and proper action taken as indicated by these examinations. The attention of the public authorities was called, from the point of view of prophylaxis, to the importance of the medical examination from the viewpoint of the teacher, and to the value of dental hygiene.

CHILD MORTALITY

In a recent report the Department of Health of New York City gives statistics on the unprecedented decrease in mortality among children under five years of age in this city during the first nine months of the year. Among children under one year of age, there were 870 less deaths than in the corresponding period of 1922; the decrease in mortality among those one year old was 1,137, and among those between two and five, 663, making a total of 2,670 lives saved. This remarkable decrease was probably due to the lessened prevalence of the four chief infectious diseases of childhood—measles, scarlet fever, whooping cough, and diphtheria. Compared with prevalence in 1922, measles showed a decrease of 747 deaths, scarlet fever a decrease of 93 deaths, whooping cough a decrease of 53 deaths, and diphtheria and croup a decrease of 307 deaths, making a total decrease of 1,197 deaths. Coincident with these decreases, there was also a marked decrease in mortality among children from respiratory diseases. The infant mortality which, the report states, is estimated upon the number of deaths of children under one year of age per 1,000 births reported, was 68 during the nine months, as compared with 76, a decrease of 8 deaths per 1,000 children born, and as the number of births reported during the year will approximate 130,000, we can look forward to a probable saving of 1,040 lives in this age group.

Although we find this marked decline in mortality among children, there was a considerable increase in deaths caused by diseases affecting middle and advanced age. Influenza showed an increase over 1922 of 280 deaths, organic heart disease of 819 deaths, chronic Bright's disease of 184 deaths, and cancer of 373 deaths. Accidental deaths increased 345. The death rate from all causes at all ages was 12.11 as compared with 12.19 for the same period of 1922, a decrease of .08 of a point.

CHILD HEALTH

In keeping with the present day feeling that health work should be preventive rather than remedial was the spirit prompting the generous donation set aside some time ago by the Commonwealth Fund to finance a complete demonstration of child health and general welfare in certain chosen cities of the United States. It was decided that these exhibits would be more forceful if held successively rather than simultaneously. The demonstration is to be administered through the American Child Health Association.

The plan includes in brief the following specifications: 1. Three demonstrations to be conducted in the same number of cities in different parts of the United States, each exhibition to include in a single unit complete educational and preventive child health activities covering the period from the prenatal life through the school life. 2. The specific form of the activities undertaken to be modified as may be necessary to insure the flexibility required for adaptation to local conditions and needs. 3. Primary consideration to be given to the welfare of the children reached in the course of the work, these children to be regarded in the light of human beings to be helped, not of subjects for experimentation. 4. The demonstrations to be conducted over five year periods in such a manner as to effect, among others, the following results: a, the indication of methods for the protection and improvement of child health; b, development of the work in cooperation with existing health agencies in such a way that a permanent and practicable plan of operations may be available and, if possible, assured after the close of the exhibitions; c, to avoid developing the work to a point where the *per capita* cost shall exceed the power of the local community to carry it.

Such a plan, if properly administered and promulgated, should be productive of vast benefits in health education, not only to the children themselves, but to parents in assisting them to give their children the proper start in life.

TYPHOID FEVER

A summary of typhoid fever conditions in New York City during the last quarter of 1923 states that 235 cases were reported as compared with 244 for the corresponding period in 1922. In seventy-four per cent. of these cases, the diagnosis was confirmed by laboratory findings. In the three months under discussion, sixty-six cases were traced to out of town infection, as compared with forty-eight in 1922. Eleven cases in Manhattan were traced to a previously undiscovered carrier working as a food handler. Four cases were traced to a child who returned ill from an out of town visit. Five cases in the Bronx were traced to a father who evidently had become infected while working as a laborer in sewer construction. Seven cases in Brooklyn were traced to two carriers in the family of a neighbor. Thus twenty-seven cases were due to four sources of infection. This summary should be of value to physicians in that it indicates that, although typhoid fever in New York City has been reduced to a relatively minor communicable disease, so that many doctors in private practice rarely see a case, nevertheless it is a disease to be seriously reckoned with as long as unrecognized carriers live among us, and many who travel fail to protect themselves and others by immunization.

News Items

Lebanon Hospital Appointments.—At a regular meeting of the board of directors held on March 16, 1924, the following appointments were passed: Attending surgeon to Lebanon Hospital, Dr. L. Miller Kahn; alumni privileges of Lebanon Hospital, Dr. Herman Frosch and Dr. Charles Weisberg.

To Honor Dr. Banting.—The Sulgrave Institution will give a dinner at the Biltmore Hotel, Wednesday evening, April 9, in honor of Dr. Frederick Grant Banting, "in recognition of his service to humanity through the discovery of insulin and as a tribute to the Canadian people who share this distinction with him."

A Critical Study of Common Methods of Fixation.—Dr. Elmel P. Weigel, assistant professor of orthopedic surgery, New York Post-Graduate Medical School and Hospital, delivered an address on Common Methods of Fixation, before the Section in Surgery of the Buffalo Academy of Medicine, Wednesday evening, March 5th, in which he called attention to the fact that recent military experience had popularized methods of treatment which were not as suitable for use in civilian practice as in war work. He believed that for most work the proper use of well made plaster was probably the most satisfactory method of applying fixation. The lecture was well illustrated by lantern slides and moving pictures.

Change of Address.—Dr. L. Merrill Henikoff announces the removal of his office and residence to the Hotel Bismark (Randolph), Chicago.

West Side Hospital and Dispensary Staff Holds Meeting.—The regular monthly meeting of the medical and surgical staff of the West Side Hospital and Dispensary was held on the evening of March 31st. Dr. Herman Goodman presented a paper on cutaneous and other manifestations of syphilis and Dr. James H. Heacock demonstrated a modified technic for intravenous medication.

Plaut Research Fund.—Dr. Edward Plaut, president of Lehn & Fink, Inc., New York, has presented the Harriman Research Laboratory with the sum of $3,000 for the year 1924, to be known as the Plaut Research Fund for Studies in Internal Medicine. This fund is to aid in the investigation of the effects of certain therapeutic agents, especially the endocrine glands. Dr. K. G. Falk has been placed in charge of this work by Dr. W. G. Lyle, director of the Harriman Research Laboratory.

United States to Participate in League of Nations Conferences on Opium Traffic. — According to cable dispatches from Geneva the United States will participate as a prominent member in the League of Nations conferences on opium traffic, which will be held in the near future. The next conference will include countries having Far Eastern possessions where opium is used and the object will be to bring about limitation, if not complete suppression, of opium consumption in the Far East. China, India, Japan, Portugal, Siam, Belgium and Italy will be invited by the council's decision to send representatives to collaborate with the committee in arranging the program of the conference.

Annual Reunion of the "Blizzard Class."—The graduates of Bellevue Hospital Medical College of 1888, known as the "Blizzard Class," will hold their annual reunion and dinner on Saturday, April 12th, at 6:30 p. m. They are to be the guests of Dr. D. Hunter McAlpin at the McAlpin Hotel, West Thirty-fourth Street, New York. If any member of the class did not receive an invitation, it was because his address was unknown. Should such a one desire to participate in the reunion, he will please notify the acting secretary, Dr. S. Adolphus Knopf, 16 West Ninety-fifth Street, New York.

Personal.—Dr. H. Douglas Singer has succeeded Dr. Ralph P. Truitt as medical director of the Illinois Society for Mental Hygiene.

Dr. Samuel Leopold is director of a mental hygiene clinic for children of preschool age, established recently in Philadelphia.

Dr. A. J. Ostheimer, of Philadelphia, has been appointed director of the recently reorganized mental hygiene division of the Public Charities Association of Pennsylvania.

Dr. David E. Hoag has been appointed clinical professor of nervous and mental diseases at the New York Polyclinic Medical School and Hospital.

Dr. Heinrich Finkelstein, professor of pediatrics in the University of Berlin, Germany, arrived in New York on March 10th, He is making a lecture tour of the United States.

Dr. Harlow Brooks was elected president of the American College of Physicians at the annual meeting held in St. Louis, Mo., February 18th to 23d.

Medical Societies to Meet in April.—The following medical societies will meet in annual session during the month of April:

Medical Association of the State of Alabama, Montgomery, April 15th to 18th, Dr. D. L. Cannon, secretary.

American Association of Anatomists, Buffalo, N. Y., April 16th to 19th; Dr. Lewis H. Weed, of Baltimore, secretary.

American Surgical Association, Baltimore, April 17th to 19th; Dr. Robert B. Greenough, of Boston, secretary.

Medical Society of Hawaii, Honolulu, April 26th to 28th; Dr. W. K. Chang, Honolulu, secretary.

Louisiana State Medical Society, Opelousas, April 21st to 24th; Dr. P. T. Talbot, secretary.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 22d to 24th; Dr. J. A. Chatard, Baltimore, secretary.

Medical Society of the State of New York, Rochester, April 22d and 23d; Dr. Edward L. Hunt, New York, secretary.

Medical Society of the State of North Carolina, Raleigh, April 15th to 17th; Dr. L. B. McBrayer, Sanatorium, secretary.

South Carolina Medical Association, Orangeburg, April 15th to 17th; Dr. Edgar A. Hines, Seneca, secretary.

Tennessee State Medical Association, Knoxville, April 8th to 10th; Dr. J. F. Gallagher, Nashville, secretary.

Western Electrotherapeutic Association, Kansas City, Mo., April 17th and 18th; Dr. Charles Wood Fassett, secretary.

Decrease in Cost of Caring for Insane.—The cost of caring for the State's insane in the thirteen State hospitals, in which were housed 7,281 patients in excess of normal capacity, showed a decrease of $1,660,182.72 for the fiscal year 1923, according to the report of the State Hospital Commission. The daily average number of patients cared for during the year was 37,936 and the general average per capital cost of maintenance was $327.86, as compared with $333.07 in 1922 and $377.54 in 1921. Total expenditures for 1923 amounted to $14,386,834.44.

Campaign to Raise $2,000,000 for Beth Israel Hospital.—The directors of the Beth Israel Hospital are preparing to start a campaign to raise the additional $2,000,000 needed to meet the cost of a new $4,000,000 building, nearing completion in Livingston Place, between Sixteenth and Seventeenth Streets. The hospital is now situated at Jefferson and Cherry Streets. In the new building, as now, the Jewish dietary laws will be adhered to strictly. It will contain five hundred beds. Each patient will have a room. The building will include a synagogue. A microphone will convey the services to bedridden patients. In the children's ward glass partitions will be erected so that mothers who cannot take their children in their arms may look upon them without danger of contracting disease. Sleeping rooms will be provided for mothers of newborn infants. The hospital is to be conducted on the lacto-vegetarian basis, no meats being used.

Gifts and Bequests to Hospitals.—Lucius N. Littauer, former member of Congress and head of the Littauer Glove Corporation of Gloversville and New York, announced plans for the building of a $300,000 addition to the Nathan Littauer Hospital at Gloversville, N. Y., which, with the Harriet Littauer Home for Nurses, he established many years ago as a memorial to his father and mother.

The will of the late Catherine B. Guernsey contains a bequest of $7,550 with which to endow a room of Hahnemann Hospital in memory of her husband, Dr. William Noah Guernsey.

The following institutions, among many others, receive $10,000 each under the will of the late Thomas D. Hurst: St. John's Hospital, Home of St. Giles the Cripple, New York Society for the Relief of the Ruptured and Crippled, Servants of Relief for Incurable Cancer, State Charities Aid Association.

A Course of Lectures on Medical Hydrology.—The University of London board to promote the extension of university teaching announces a course of lectures on Medical Hydrology, supplemented by demonstrations in London and by a study tour to Bath and Cheltenham. The course is being arranged by the board in cooperation with the committee for the promotion of teaching of medical hydrology (representing the International Society of Medical Hydrology and the Section of Balneology and Climatology of the Royal Society of Medicine). It will take place at the University in the week commencing May 5, 1924. The lectures will comprise one or more physiological discourses on the action of natural remedies, and systematic lectures on the treatment of incipient and chronic disease by means of waters and baths. The fee for the course is three guineas. Particulars may be obtained on application to Hon. Sec., Hydrology Teaching Committee, c/o University Extension Department, University of London, Imperial Institute Road, South Kensington, S.W.7. A complete programme will be issued in due course.

Philadelphia Physician Reports Health Conditions Improving in Austria.—Dr. Mary Griscom, a well known Philadelphia physician, who has spent the last nine months in relief work for the American Friends Service Committee in Austria, has just returned to America. Dr. Griscom had charge of the antituberculosis work for the Service Committee in accordance with a program supported by that organization and the Austrian Department of Health in a fight against the menacing plague which threatened the lives of tens of thousands of their children. Dr. Griscom has been associated with Dr. von Pirquet in Vienna. Teachers are trained in antituberculosis and child care methods in von Pirquet's clinic, then are sent out into the remote districts of the provinces to give instruction in the homes and schools. The Austrian Government is fast regaining her ability to cope with her gigantic health problems, says Dr. Griscom. The Friends Service has been able to save the lives and health of hundreds of children by making it possible for them to have medical attention and suitable food.

Foreign Correspondence.

LONDON LETTER

(*From our own correspondent*)

London, *February 17, 1924.*

CHEAPER INSULIN

Investigations have been made and are still going on at the Biochemical Department of the Bland-Sutton Institute of Pathology, Middlesex Hospital, London, with a view to determining whether any simplification could be effected in the method now in general use for the preparation of insulin. These investigations have been conducted by Mr. E. C. Dodds, chemical pathologist to the Middlesex Hospital, and Mr. F. Dickens, assistant in biochemistry department, Middlesex Hospital, and described in the *Lancet,* February 16th last. There is no space here to enter into the details of the method; suffice it to say that the method opens the possibility for a substantial reduction in the price of insulin. It appears that the process of manufacture can be hastened and perhaps the use of alcohol dispensed with in its preparation. This would render the manufacture of the remedy comparatively inexpensive. It may be said that insulin prepared by the water extraction process described in the *Lancet* has been employed clinically on four human subjects and up to the present has been satisfactory. As said before investigations are being continued. If a cheap means of making insulin can be discovered no one suffering from diabetes will be compelled to forego a mode of treatment which, on the whole, has been remarkably successful and has supplied one of the brightest pages in the history of therapeutic medicine. If, moreover, a preparation can be prepared which is effective by oral administration a still greater triumph will have been won. It seems that we are traveling in that direction.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, LONDON

Special courses in children's diseases were given at the Royal Waterloo Hospital, London, from March 17 to April 5, 1924. Subjects were dealt with by lecture demonstrations, ward work, outpatient clinics and operations by various members of the staff.

EPIDEMIC OF INFLUENZA

The epidemic of influenza which up to the present time has been of a comparatively mild type is increasing both in prevalence and virulence. In London last week the death rate reached twenty in a thousand; the average for the whole year 1923 was 11.2. This rise is entirely due to influenza, the most deadly disease known in Great Britain and probably in any country. But the deaths ascribed to influenza, although large, represent but a tithe of the total mortality. In order better to understand what the menace of influenza really is it is necessary to watch the death roll from bronchitis, bronchopneumonia, and heart disease and the modifications of pneumonia. It is not influenza in itself that is so deadly but its complications, and the sapping of vitality which renders its victims susceptible to other infections or diseases. The complications with the streptococci, the most dreaded of all, have not been very evident as yet, but unfortunately these complications generally occur when an epidemic has been under way for a considerable time. In Leeds, the largest manufacturing town of Yorkshire, the influenza scourge is becoming somewhat alarming. There has been a marked increase in the number of deaths at all ages from influenzal pneumonia and pneumonia, while during the past two weeks the infantile death rate has gone up by leaps and bounds. The deaths have been due mainly to influenza, whooping cough and bronchopneumonia. The number of infants suffering from the last mentioned complaint is very large. In other districts of Yorkshire influenza is very prevalent.

STREET NOISES IN LONDON

An invalid lying in a London nursing home writes to a daily journal giving his daily street noise chart: 9 to 11 a. m., organ recital, gay, topical, damnable, favorite tune, *On the Back Porch;* 11 to 1.30, drum and fife band, melodies unrecognizable; 2 to 3 p. m., brass band, semireligious, also return of organ, sudden arrival of another organ; 3 to 5 p. m., distant organs and bands and near harmonium, vocalists; 7 to 10 p. m., wireless, loud speaker, brass bands, drum and fife band, harmonium, organs, grand chorus of motor horns. When the invalid gets well and goes out into the world he discovers that it is not legal for him to whistle for a taxicab or to drive a motor car with a noisy exhaust.

BRITISH EMPIRE CANCER CAMPAIGN

The British campaign against cancer, launched a few months ago, is proceeding apace. An advisory committee has been appointed following a conference between representatives of the Royal Society, the Medical Research Council and the British Empire Cancer Campaign, to administer the funds of the campaign. The following have consented to serve on the Committee: Sir John Bland-Sutton, president of the Royal College of Surgeons; Dr. H. H. Dale, C.B.E., F.R.S., head of the department of biochemistry and pharmacology under the Medical Research Council; Sir Richard Garton, G.B.E.; Dr. F. Gowland Hopkins, F.R.S.; Sir William Dunn, professor of biochemistry in the University of Cambridge; Dr. Robert Knox, director of electrical and radiotherapeutical department, Cancer Hospital; Sir William Leishman, K.C.B., K.C.M.G., F.R.S., director general, Army Medical Service; Professor C. T. Martin, C.M.G., F.R.S., director of the Lister Institute of Preventive Medicine; Dr. Robert Muir, F.R.S., professor of pathology in the University of Glasgow; Sir Humphry Rolleston, K.C.B., president of the Royal College of Physicians. The formation of this committee, half the members of which are appointed jointly by the Royal Society and the Medical Research Council, marks a long forward step in the process of completing the main organization of the British Empire Cancer Campaign, whose appeal for funds to endow and subsidize research on the causes and treatment of cancer has been undertaken by the British Red Cross Society. Since the appeal was first made in May last it has met with a fair measure of success, and subscriptions received both from home and Empire sources already amount to more than £70,000. Though much more money is needed for the investigation of cancer, a group of

morbid conditions rather than a single disease, is so complicated and must be so widespread that a million pounds might readily be spent without suspicion of waste. It is not intended to hold up the work until any specified total sum has been subscribed.

The British Empire Cancer Campaign proposes to begin by applying its funds to the fostering of research as they are received and at the earliest possible moment. It is here that the advisory committee will have a prominent part to play. Its functions will be to devise schemes of research, to advise and report upon all questions relating to research, including the allotment and application of funds. It will also be closely concerned in maintaining communication between research workers all over the world, making their results and discoveries mutually available, and in keeping the public informed of the nature of the problems to be solved and the progress made towards their solution. The distinction and knowledge of the members of the committee are in themselves a guarantee that no branch of research will be neglected, and that money devoted to encouraging any of them will be spent wisely and well. The aim of the British Cancer Campaign is to co-ordinate and combine all research work on cancer, to prevent overlapping, and to fill up gaps where now there are few or no workers.

LATIN AMERICA LETTER

(From our own correspondent)

BALBOA, CANAL ZONE, *February 1, 1924.*

PANAMA'S SPOKESMEN NAMED

President Porras has announced by Executive Decree that the delegates from Panama to the Conference of the Maritime Quarantine Authorities of the West Coast of South America will be Dr. Augusto S. Boyd, chief surgeon of Santo Tomás Hospital, and Dr. William Colby Rucker, chief quarantine officer. Dr. Boyd, who is also the president of the Junta de Sanidad Nacional, is the chairman of the Panaman Delegation and Dr. Rucker is the secretary-general of the conference.

Dr. Sebastián Lorente, accompanied by his wife and Dr. Carlos Enrique Paz Soldan will arrive at Balboa on the S. S. *Santa Elisa* of the Grace Line on February 18th as the delegation from Peru. Dr. Lorente is the national director of health of Peru and Dr. Paz Soldan is professor of hygiene in the University of Lima and the editor of *La Medica Reforma*. The Peruvian delegation will bring as its secretary, Mr. Humberto Rebagliati, who will be accompanied by his wife and sister-in-law, Senorita Cortez. Unfortunately, Dr. R. Corbalón Melgarejo, director general of health of Chile, has been prevented by sickness from attending the conference, but Chile will be represented by Dr. Tomás Aravena, chief quarantine officer of Arica, Chile.

Surgeon S. B. Grubbs, U.S.P.H.S., former chief quarantine officer of the Panama Canal and health officer of the Port of New York, will leave New York on February 6th and after spending a week in Jamaica will arrive for the conference on February 21st. Assistant Surgeon General John D. Long, U.S.P.H.S. who is in charge of the maritime quarantines of the United States, will arrive on the S. S. *William C. Gorgas* on February 23rd. Doctor Long comes as the delegate of the Pan-American Sanitary Office and is expected to be one of the leading figures of the conference. On the same day, Dr. Carlos A. Miño, deputy national health commissioner of Ecuador and health officer of Pinchinchi and Quito will arrive. The secretary of the Ecuadorian delegation is Mr. Saens de Tejado.

The National Theatre has been selected as the place of meeting for the conference. Dinners and luncheons will be given for the delegates and observers by the Panaman Government, the Chamber of Commerce, the Herrick Clinic, the Panama Agencies, the Rotary Clubs of Colon and Panama and the Isthmian Canal Medical Association. The program will include formal discussions by the delegates and demonstrations at Santo Tomás Hospital, Ancon Hospital, the Panama Hospital, the Board of Health Laboratory, the Palo Seco Leprosarium and the Miraflores Water Purification Plant. At Colon and Panama there will be demonstrations of municipal sanitation in all its phases. Visits will be paid to the gigantic refrigeration plant at Mt. Hope and the Mindi Dairy Farms. An interesting demonstration will be the fumigation of ships with cyanogen chloride.

ROTARY CLUBS GET BEHIND HEALTH MOVEMENT

The Rotary Clubs of Panama and Colon have included in their annual programs the stimulation of national preventive medicine as a governmental function. These plans include the extension of the dispensary system in the interior so that it will include prevention as well as cure; the attack upon tuberculosis, hookworm disease and malaria; child hygiene, particularly with relation to the spread of public health teaching in the public schools; and the utilization of the forces of the Rockefeller Foundation to the fullest extent. Panama is developing a strong sense of sanitary consciousness; two physicians have been recently sent to the United States to be educated in public health work; the citizens of the capital and of Colon are pushing their demand for a greater sanitary activity on the part of the national and local governments; in fact a genuine public health awakening is being fostered and stimulated by the Rotary Clubs as the representatives of the most wide-awake portion of the business population.

PSYCHOSES OF THE ISTHMUS OF PANAMA

Dr. Louis Wender, who for several years was the superintendent of the Corozal Hospital for the Insane, in an article appearing in the October, 1923, issue of the *American Journal of Psychiatry,* under the caption, Types of Psychoses Prevalent on the Isthmus of Panama, presents a statistical study based upon two years' admissions to that institution, which has excited considerable interest here. He notes the predominance of dementia precox among the white population, the disproportion of neurosyphilis between colored females and white males, and the preponderance of cerebral syphilis over paresis among colored patients. The absence of psychoses associated with pellagra among Panamanians which he notes may be explained by the constant inclusion of beans in their dietary. The relative rarity of manic depressive psychoses among colored West Indians of which he speaks is in accordance with the observations made by other physicians.

Book Reviews

SYPHILIS AND UROLOGY

Genitourinary Diseases and Syphilis. By HENRY H. MORTON, M.D., F.A.C.S., Professor of Genitourinary Diseases and Syphilis, Long Island College Hospital, etc. Fifth Edition. Revised and Enlarged. With 328 Illustrations and 38 Full Page Colored Plates. New York: Physicians' and Surgeons' Book Company, 1924.

The fifth edition of Morton's deservedly popular work appears from the press bigger and better than its predecessors. Dr. Morton has called to his aid a number of his colleagues on the faculty of the Long Island Medical College, who have written special chapters on selected topics. This volume represents the most recent thought in urology and syphilis, though we observe a tendency to overlook the finer details in diagnosis and therapy, many of which are of great importance to the practitioner brought face to face with the actual problem of making a diagnosis or administering treatment.

Morton's reputation as a urologist of ability and skill is well known. His teachings, as exemplified in this work, are orthodoxly conservative, yet modern in every respect. The student or practising physician, seeking information on the diseases of the urinary tract or on syphilis, can depend on this volume as a safe and trustworthy guide. It is written in an interesting style, the printing and illustrations are excellent, and the subject is well covered in every branch. On the whole, Dr. Morton has made an unusually welcome contribution to the American literature on urology and syphilis.

LABORATORY DIAGNOSIS OF SYPHILIS

Laboratory Diagnosis of Syphilis. A Manual for Students and Physicians. By HIDEYO NOGUCHI, M.D., M.S., Ph.D., D.Sc. With Fifty-nine Illustrations, of which Thirteen are in Color. New York: Paul B. Hoeber, Inc., 1923.

It goes without saying that the subject of this volume would be treated adequately by so eminent a serologist as Noguchi, and the reader will not be disappointed in this expectation. Step by step the author proceeds by easy stages through the various laboratory procedures which have been developed around the diagnosis of syphilis, beginning with a careful study of serum hemolysis and closing with a detailed account of the methods for the detection and study of the treponema pallidum.

The author has devoted considerable attention to the microscopic demonstration of the pallidum, and besides enumerating the standard procedures, he has described in detail the new Tilden method, which makes it possible to stain the organism with the ordinary basic aniline dyes, as well as by silver impregnation, or to examine them unstained but well preserved by darkfield illumination.

Noguchi believes that none of the many modifications in technic in the Wassermann reaction which have been proposed, has changed fundamentally the methods already generally recognized. He discusses the steps that have been taken to "standardize" the reaction, but feels that no amount of accuracy in complement, antigen or other factors will be of any value so long as the amboceptor is not quantitatively adjustable. The chapter on the luetin reaction has been considerably abbreviated, but the author has not changed his earlier views regarding its diagnostic value in certain chronic cases in which the Wassermann test gives an indecisive result.

The author and publisher have combined to produce a most attractive and useful work which can be commended as authoritative and dependable.

SURGICAL UROLOGY

An Introduction to Surgical Urology. By WILLIAM KNOX IRWIN, M.D. Aberd., F. R. C. S. Edin. New York: William Wood and Company, 1924.

The author has aimed to encompass within a small volume the main features involved in the pathology, diagnosis, and treatment of diseases of the genitourinary system. The two first chapters are devoted to a consideration of the anatomy and congenital abnormalities of the urinary tract. These are followed by chapters dealing with frequent micturition, incontinence of urine, difficult micturition, retention of urine, genitourinary pain, hematuria and pyuria, the last chapter being devoted to the senile and cancerous prostate.

Considerable useful information has been condensed within a small space, it is true, but it is doubtful whether the result has justified the effort. As an aid to the medical student in passing examinations, the volume can be said to have much value; perhaps the general practitioner will likewise find it a useful addition to his working library; but there does not seem to be any particular justification for this brief résumé of so important a subject when there are so many good textbooks which deal with it more fully and comprehensively. There are no illustrations and no bibliography; the book is well written and neatly printed.

PRURITUS OF PERINEAL REGION

Pruritus of the Perineum. Pruritus Ani, Vulvæ and Scroti. By JOSEPH FRANKLIN MONTAGUE, M.D., of the Rectal Clinic, University and Bellevue Medical College. Foreword by GEORGE DAVID STEWART, M.D. With thirty-seven illustrations. New York: Paul B. Hoeber, Inc., 1924. Pp. 181.

Based on eight years of observation and experimentation in his special subject, the author has written a most interesting and instructive monograph. His writing, as he states, is not merely a compilation of the work of others, but represents an analysis of other opinions and gives an explanatory theory of his own. The theory of infection by streptococcus fecalis is vigorously assailed and an unusual amount of bacteriological work is offered to refute it. Not only does the author show an intimate knowledge of bacteriological methods but writes in a convincing way on anatomy, physiology and pharmacology.

He divides the subject of pruritus of the perineal region (including anus, vulva and scrotum) into direct and indirect pruritus. Direct pruritus, which he terms pruritus ani, is due, he says, to direct irritation of the peripheral nerve endings in the pruritic zone. Indirect pruritus, on the other hand, which he terms anal pruritus, is due to a misreference in sensation resulting from a transference of an irritable stimulus from visceral afferent nerves to normal

somatic afferent nerve channels or pathways. This is analogous to misreference of pain, but is not a true reflex action. The fact that such a misreference of sensation indicates pathological changes elsewhere than in the area of apparent disturbance, is, he says, of outstanding clinical importance. As a symptom of visceral disease or derangement he considers that its value cannot be overestimated. The various methods of local treatment are described though too little importance is given to x ray therapy, at least as a palliative measure.

The book is well illustrated by photomicrographs of histological and bacteriological preparations, by clinical photography, charts and representations of instruments and various operative procedures. The work of the publisher regarding the paper, print, illustrations, and general appearance of the book is unusually good. A bibliography with 230 references is appended.

ACUTE DISEASES OF ABDOMEN

Diagnosis and Treatment of Acute Abdominal Diseases. Second Edition. By Joseph E. Adams. New York: William Wood & Co., 1923.

In this book Adams describes the acute diseases and injuries to which the abdomen and its contents are liable, treating these conditions from the point of view of both physician and surgeon. The author utilizes his great experience in determining the best method of treatment. In making a diagnosis Adams lays great stress on taking a careful history. He says:

"The importance of taking a careful and complete history in every case of acute abdominal disease can hardly be overestimated; the information gained thereby is at least equal to that derived from the physical examination of the patient, and in many cases it is of greater value. Many correct diagnoses can be made from the history alone; the majority of diagnostic errors are due to carelessness in history taking. Consider, for example, the following case:

"A man, aged eighteen, was brought up to hospital with a history of a severe attack of pain in the right iliac fossa of eight hours' duration; he had vomited twice at the onset. On inquiry it was discovered that he had been laid up previously with similar attacks of rightsided abdominal pain. His temperature was 101.2°, pulse 120, respiration 28; his tongue was slightly furred and his expression anxious. There was definite tenderness over the right iliac fossa, most intense in the vicinity of McBurney's point, and associated with local macular rigidity.

"The obvious diagnosis was made and immediate operation advised. A perfectly healthy appendix was discovered. A subsequent x ray examination revealed a calculus in the pelvis of the right kidney. Then, and only then, was elicited the fact that two of the previous attacks of pain had been associated with the passage of smoky urine, and that the pain of the earlier attacks had been definitely lumbar in origin; information which, obtained in the first instance, would have saved the man an entirely unnecessary operation."

Pain is another very important symptom helpful in establishing a diagnosis. Adams details several varieties of pain with the following words:

"Peristaltic pain, or colic, is associated with violent intestinal peristalsis, whether due to organic intestinal obstruction or not. It is characterized by its paroxysmal nature and usually by its severity. Between bouts of agonizing, griping pain, the patient may be more or less comfortable, even entirely free from pain. Oddly enough gastric peristalsis, however vigorous, is almost invariably painless. The pain of peritonitis is constant; but there may, of course, be a superadded peristaltic pain evidenced by exacerbations of griping. The pain due to an abscess in the abdomen, as elsewhere, is often described as throbbing; and the pains associated with gallstones are sometimes said to be stabbing pains, i. e., shooting straight through from the front to the back, as contrasted with renal pain which passes from back to front round the body."

Everything pertaining to diagnosis and treatment is described with great detail. The book can be highly recommended as a useful addition to the practitioner's library.

THERAPEUTIC TECHNIC

Therapeutische Technik für die ärztliche Praxis. Ein Handbuch für Arzte und Studierende. Bearbeitet von Prof. Dr. S. Bettmann in Heidelberg; Geheimrat Prof. Dr. J. Boas in Berlin; Dozent Dr. A. Fernau in Wien; Geheimrat Prof. Dr. E. P. Friedrich (Kiel) in Friedrischsroda unter Mitwirkung von Dr. G. Albanus in Hamburg; Prof. Dr. H. Gocht in Berlin; Geheimrat Prof. Dr. C. v. Hess in München und Prof. Dr. W. Lohmannin Schuelm i. W.; Geheimrat Prof. Dr. O. Hildebrand in Berlin; Prof. Dr. G. Holzknecht in Wien; Geheimrat Prof. Dr. G. Hoppe-Seyler in Kiel; Prof. Dr. R. Th. v. Jaschke und Prof. Dr. P. W. Siegel in Giessen; Geheimrat Prof. Dr. F. König in Würzburg; Geheimrat Prof. Dr. Fr. Kraus und Prof. Dr. Th. Brugsch in Berlin; Prof. Dr. Ed. Müller in Marburg a. L.; Prof. Dr. H. Rieder in München; Prof. Dr. F. Siebenmann in Basel; Geheimrat Prof. Dr. W. Stoeckel in Leipzig; Prof. Dr. W. Straub in München; Prof. Dr. F. Voelcker in Halle a. S.; Prof. Dr. R. Volk und Dr. M. Ostermann in Wien; Hofrat Prof. Dr. O. Walkhoff in Würzburg; Geheimrat Prof. Dr. A. v. Wassermann und Geheimrat Prof. Dr. M. Ficker in Berlin-Dahlem; Prof. Dr. R. Werner in Heidelberg. Herausgegeben von Prof. Dr. Julius Schwalbe, Geh. San.-Rat. Mit 685 Abbildungen. Sechste, Auflage. Leipzig: Verlag von Georg Thieme, 1923.

This is the sixth, improved and enlarged edition of this encyclopedic work on therapeutic technic, revised only two years after the previous edition. A chapter on obstetrical technic, written by v. Jaschke and Siegel, has been added to complete the subject of therapeutics. All the various chapters and even subdivisions of some of them, as that on radiology, have been written by the masters in their respective specialties. The chapters are arranged as follows: the preparation and application of drugs, including drinking and bathing waters; immunotherapy; dietotherapy, hydrotherapy, thermotherapy, the various forms of irradiation therapy, including radium and mesothorium, massage, gymnastics, mechanical orthopedics, various surgical procedures, treatment of skin diseases and syphilis, the nutrition of the healthy and sick infant and the treatment of individual organs and systems of organs. This is the most complete single volume on the subject and it contains a great amount of material which is not mentioned or described in such profuse detail in other works on therapeutics.

SURGICAL CLINICS

The Surgical Clinics of North America. Volume III, Number 5. Minneapolis-St.Paul Number. Published, October, 1923. Philadelphia and London: W. B. Saunders Company.

Twelve clinics and one contribution constitute the material of this most interesting number of the *Surgical Clinics*. The contribution by Farr, on Some Helpful Surgical Adjuncts and Methods, is admirable, not only in the text matter but likewise in its splendid and numerous illustrations. More of these contributions would make the *Clinics* still more valuable to the practitioner interested in surgery as a performer, rather than as an observer. Of the clinics, special mention must be made of Thoma's on urological subjects, J. D. Lewi's clinic on external nasal deformities of traumatic origin, and Lerche's clinic on multiple strictures of the esophagus and hourglass stomach following lye poisoning. The usual high typographical standard is fully maintained in this volume.

PHILOSOPHY OF CIVILIZATION

The Philosophy of Civilization. By R. H. TOWNER. In Two Volumes. New York and London: G. P. Putnam's Sons, The Knickerbocker Press, 1923. Pp. ix-290; iii-340.

Here is a writer earnestly desirous of turning the current of forces at work against the permanency and improvement of our civilization. He is not afraid to challenge institutions long cherished or movements heralded by many as great signs of progress toward the betterment of mankind. He challenges them where they most deceive us, reversing them so that the subtle dangers which they conceal become apparent. He asks us to consider the place which alcohol has played in building up civilization rather than in casting it down and sounds a serious warning against the false ideal of its disuse. He attacks the enforcement of conformity against the more vital diversity which has prevailed in regard to literacy and other conventionally esteemed benefits of modern civilization. He points out in the same way the evils of espionage and of authoritative dominance in any direction. He discusses the place of God in the development of man, the relation of intellect and emotion, and points out the differences between a fortuitous civilization and one consciously directed. He urges the latter as the means of yet rescuing civilization from the evils preying upon it and which have overthrown civilizations in the past.

Thus the book has much in it to enlist thought. But it is full of weakness too. It is the second volume in which one finds this more valuable matter. Yet even here, as more completely in the first volume, the author gathers together much material to which he offers too credulous and uncritical a mind. He himself seems not to have cast off an obedience to authority in thinking which leads him to accept traditions and "historical" statements without the criticism of a mind demanding scientific accuracy. The faults of his book are due also to his apparently astounding ignorance of psychology and his ignorance or carelessness in the use of biological facts. Through these he permits himself to follow certain narrow perspectives, tempting and deceptive because they lead to such marvelous lengths. They have not the breadth which would give his thought a far more convincing relation to the practical needs which a sick civilization lays before us. His ignorance of these two fundamental sciences, or his careless handling of them, weakens his logic. It makes possible the development of such a thesis as that which fills his first volume and obtrudes itself amid the more sincere thought of his second volume. This thesis is that the rise and preservation of progressive civilizations depend upon motherhood through frigid women. Their aversion to sexual life is then passed on to the offspring to make a race endowed with a higher nervous organization. When various factors, religious or otherwise, disturb this situation and the population is recruited mostly from women who enjoy their reproductive function, the sexual union at least, then civilization declines. The passion of the father may be always the same. Apparently paternity has no place in heredity or in this immediate heredity. The exaggerated insistence upon this theory and the author's uncritical reliance upon whatever he may heap to its support indicate the weakness which pervades a book that contains much of good.

EVOLUTION AND EUGENICS

Studies in Evolution and Eugenics. By S. J. HOLMES, Ph.D., Professor of Zoology in the University of California. New York: Harcourt, Brace and Company, 1924. Pp. v-261.

Holmes has written a book in brief chapters which bring instruction and stimulus to further thought in a very direct, simple form. There is a review of the theories through which the science of evolution has gradually won its way and is still pressing into the knowledge of life. The various theories examined by the author are presented chiefly in their historical setting as others have propounded them, tested them as to their usefulness, rejected them, modified them, or advanced new ones upon them. The writer makes it clear that these theories belong to a science that is young and one, because of the subject with which it deals, difficult to formulate with authoritative precision. Some of the theories of heredity and of the facts which slowly come to light might have led the writer on still further, one feels, and so might have many of the psychological implications, chiefly in the latter part of the book.

Yet we can not quarrel with him because he has remained the biologist throughout and examined not only theoretical matters but certain very practical problems of the day with the objective fairness of the biologist's point of view. This has led him to avoid all dogmatic statement and to examine each question from even opposing aspects. On a biological background there is no true opposition, only a dispassionate search for facts upon which to act. One feels that sociologically and biologically more facts should have been assembled as, for example, in the discussion of the negro problem. Yet one is only stimulated to further question and examination for himself upon the pertinent matters discussed. These are birth control, immigration, eugenics, race mixture in general and especially the position of the negro in our country. Absolutely dispassioned a writer cannot be. One finds here an optimistic spirit which tends in some degree to overweigh facts. This, however, is not obtrusive enough to depreciate the value of the book.

Medicoliterary Notes.

Visual Education is the title of a volume announced by the University of Chicago Press. It will record the results of experiments made under the direction of Professor Frank N. Freeman, of the department of educational psychology of the University of Chicago, in the public schools of Chicago and other Illinois cities and towns, in the use of motion films and other means of visual instruction. The experiments were financed by a special grant from the Commonwealth Fund to the University.

* * *

The medical department of a recent issue of the London *Times* contains an interesting discussion of periodical health examinations. It was recently suggested to the English medical profession, and, strangely enough, by a dock hand, not an insurance company, that policy holders submit each year to a medical "overhaul," and that a rebate or premium be allowed to those who should agree to follow this procedure.

* * *

Anatole France's preface to Pierre Calmette's new book, *Les Poupées de Paris,* propounds the theory that the declining birth rate of France is due in part to the recent craze for fantastic dolls among the women of the French capital. He declares that the women of France are forgetting their duty to the race and the nation in "playing dolls."

* * *

Geography and Natural Selection was the title of an interesting paper read by Professor Ellsworth Huntington, of Yale University, at a recent meeting of the American Association for the Advancement of Science. Professor Huntington gave some of his views as to why Australia has a lower death rate than any country in the world except New Zealand. He believes that the explanatnon of this and of the prosperity of the country is to be found in natural selection. Australia is so far away from the rest of the world that only healthy and fairly prosperous people are likely to journey there, and, since the climate is good and living conditions favorable, these people form a healthy stock and have healthy children.

* * *

A press notice from France announces that Dr. Georges Gautier spoke recently before the French Academy of Medicine on his new method of improving respiration. After many years' study and experimentation, he has developed a method of enlarging the air passages, so he states, that will do away with colds, hay fever, asthma, headaches, deafness, and snoring.

* * *

In rural districts of Germany dried leaves are being used as food for animals. This leaf hay is first dried out of doors and then artificially and a product similar to bran is obtained.

* * *

A unique collection of books and manuscripts has been lost through the Japanese earthquake, including the Korean *Chronicles of the Li Dynasty in* 790 volumes; the *Topography of Japanese Counties and Towns,* 6,400 volumes; and the great Chinese *Encyclopedia* in 9,998 volumes.—*Living Age.*

* * *

Another recent volume of near human animal, including fish, stories, is that of Horacio Quiroga, entitled *South American Jungle Tales.* The stories are told with the utmost quaintness and naïveté, until one almost believes that the writer is taking himself and his subjects seriously.

* * *

Two books have been published recently by William Heinemann, Ltd., London. One of these *Psycho-Analysts Analyzed,* by Dr. P. McBride, is a criticism of psychoanalysis. The author denies that psychoanalysis is based on science, and gives his reasons for his views. The book is ably written.

* * *

The other book is *The Culture of the Abdomen,* by F. A. Hornibrook, with a preface by Sir Arbuthnot Lane, Bart. M. S. Mr. Hornibrook is a skilful exponent of physical culture, and all that pertains to it. He believes in the gospel of physical fitness, and has worked out for himself successful methods of bringing this about. He first tried the methods on himself, thereby reducing his weight, while at the same time gaining greatly in health and vitality. As described by himself these are methods whereby it is possible to localize effort to the abdominal region to promote more internal abdominal activity, and to concentrate on correct posture. Posture is the keynote of the system. The book is well written and well illustrated.

* * *

A portion of New Jersey is carrying on a vigorous anti-rat campaign. Monmouth County is reported to harbor at least one hundred thousand rats, and a ton of poison is being used to eradicate them.

* * *

The *Child's Health Magazine* is the new name for *Mother and Child,* published by the Child Health Association. The pages of the new publication are twice as large as formerly and the number of illustrations has been greatly increased.

* * *

William Beebe, the zoologist, is directing an expedition to British Guiana which hopes to bring back, among other specimens, a living hoatzin. This is a strange bird whose young have claws on their wings, with which they climb through the foliage of mangrove trees in which they live. Attempts have been made before to bring these birds to this country, but their diet apparently is limited to one kind of tropical plant, without which they die.

* * *

Dr. J. C. Curran, medical director of the Near East Relief, is helping to organize a nation wide campaign for condensed milk to use in the work of the association. A transcontinental milk train will be run from Los Angeles to Baltimore for the purpose of collecting one million cans of condensed milk.

* * *

"Is There a Foolproof Science?" is the title of an article in a recent number of the *Atlantic.* L. P. Jacks, the writer, believes that there is not, not only in natural science, but in philosophy and religion, all three of which, he states, should be working together in the pursuit of truth instead of quarreling with one another. "May we not say," he writes, "that a naturalist who makes a human use of natural science is nearer the kingdom of God than a supernaturalist who makes inhuman use of supernatural science?"

* * *

Dr. B. Liber, author of the *Child and the Home,* has a new book just out which he calls *As a Doctor Sees It.* It consists of a number of short stories of life as the physician finds it. Dr. Liber has illustrated the volume himself.

* * *

The Eyesight Conservation Council of America has inaugurated in the schools of the South an eyesight conservation campaign similar to that recently brought to a close in New York, New Jersey, and the New England States. The council is being aided in its efforts by U. S. Commissioner of Education Tigert and other Federal and State officials.

* * *

We read in press notices from two different New York papers that Hungary has banned by law as not fit for the public's morals *Yes, We Have No Bananas Today"* and Victor Margueritte's *La Garçonne.*

* * *

The Association for the Prevention and Relief of Heart Disease is endeavoring to raise a budget of $20,000 for its work during 1924. The association is supported entirely by membership fees and voluntary contributions. Twenty-nine New York hospitals are working in cooperation with it, and it has established forty-three cardiac clinics where six thousand patients are being treated. Dr. Haven Emerson, the president, states in a recent letter to the press that heart disease is now the most frequent single cause of death. Last year its toll was 155,000 lives.

* * *

Are Parents People? is the title of the first of a collection of short stories by Alice Duer Miller, written in her usual amusing and entertaining style.

* * *

Dr. William H. Park, of New York, read two papers at a recent monthly meeting of the Atlantic County Medical Society at Atlantic City, N. J., in which he told of results he had obtained at the Willard Parker Hospital during eight years of experimentation with inoculation against measles. This he does by means of a few drops of blood from a convalescent, creating immunity for several weeks, sometimes for a few months.

Abstracts from Current Literature

PEDIATRICS

Acidosis in Infants and Children.—Julius H. Hess (*Northwest Medicine,* November, 1923) says that the treatment of acidosis must first be directed to the prevention of a further production of more acids; second, to replenishing the alkali reserve; third, to the elimination of the acids and their salts; and, fourth, to the treatment of the underlying factors, whether they be acute infections, starvation or organic diseases.

Large quantities of water should be administered by mouth, if it is tolerated. When not retained, subcutaneous or intraperitoneal administration of normal saline or Ringer's solution is to be recommended, the latter as often as every six hours, if necessary, during the early treatment. The total quantity of all fluids given should be recorded daily and every effort made to administer maximum quantities.

In the presence of nondiabetic acetone body acidosis, glucose should be given in all cases. Three methods of administration are available, namely, by mouth, rectum, or intravenously. By mouth, a five to ten per cent. solution may be administered every two to four hours, in quantities depending upon the age of the child and the tolerance of the gastrointestinal tract. By rectum, a five per cent. solution is best employed, which may be administered intermittently at intervals of three or four hours, quantities varying from sixty to one hundred and twenty c.c. (two to four ounces) being used, or in young infants and older children who are not too restless the drip method may be used. When there is a tendency to return the glucose solution, it may be necessary to compress the buttocks for at least a half an hour after each administration.

A careful record should be kept of all solutions administered by this method and so far as possible the retained fluid estimated. In most cases a litre can be administered in the course of twenty-four hours. For intravenous use, five or ten per cent. of glucose in Ringer's or normal saline solution may be used, depending upon the size of the child. From sixty c.c. in small infants, to three hundred c.c. in older children, may be injected at one time, to be repeated as indicated. For intraperitoneal injection normal saline or Ringer's solution may be used. Fifty to five hundred c.c. may be administered by the gravity method. Glucose should not be administered intraperitoneally.

Alkalies are given a secondary place in the therapy of acidosis, due to concentration of ketone acids in young children. Glucose rather than bicarbonate is the prime agent in the treatment of nondiabetic ketosis. The same is true of the lactic acid type. If administered, sodium bicarbonate should be given by mouth or intravenously. By mouth from one to two gm. may be given at four hour intervals, dissolved in water. For intravenous use a two per cent. solution is best employed, as it is isotonic with the blood. The same amounts of solution can be administered intravenously as recommended for the administration of glucose.

While the administration of glucose as recommended may carry the patient over the first emergency period, insufficient amounts of carbohydrate are given in this way to meet its needs. Efforts should, therefore, be directed toward the further administration of carbohydrates by mouth as soon as the condition of the stomach permits. After a short period of rest, the time of which will be indicated by the ability of the stomach to retain inert fluids, which in most instances, is not over six to twelve hours, further administration of sugars and cereals should be begun.

Thick cereal pastes, to which cane sugar or maltose dextrose compounds have been added, are usually best retained. They may be given in small quantities at two hour intervals, or at longer intervals with the administration of corn or maple syrup, or honey in teaspoonful or larger amounts. Malted milk is often well taken. Milk chocolate and plain candy, such as caramels, are valuable and are usually well taken by children who have eaten them previously and have a liking for them. Various plain wafers sold on the market may be tried on the second day. Fruit juices sweetened, more especially orange juice, should be given in small quantities. If orange juice is retained, larger quantities diluted with sweetened water should be given and continued. Often one or more oranges can be fed in twenty-four hours during the first day after vomiting ceases. Skim milk, or better skim buttermilk, can usually be given by the third day. Whole milk and fats should be withheld until the child is convalescent. The feeding of carbohydrates should be pushed as a preventive measure in the presence of acute infections.

The acute symptoms requiring further medication are gastric and intestinal distention and the retention of decomposing food in the intestinal tract, vomiting and syncope. To clear the intestinal tract milk of magnesia or some other mild saline laxative, together with enemata, are best. For vomiting in the presence of gastric distention lavage with a weak bicarbonate or citrate solution is often most beneficial. Small doses of carbolic acid, administered at two hour intervals for three or four doses, together with tincture opii camphorata for the relief of vomiting and restlessness, are indicated. In the presence of syncope it may be necessary to administer cardiac and respiratory stimulants.

In extreme cases of socalled epidemic acidosis, blood transfusion has, in the limited number of cases in which we have had occasion to resort to this measure, yielded striking results.

The indicated treatment for underlying chronic respiratory, cardiac and renal conditions, if present, must be instituted, following the subsidence of acute symptoms.

Treatment and General Management of Eczema in Infants in Private Practice.—Alan Brown (*Canadian Medical Association Journal,* December, 1923) says that while the exact underlying causes are not clearly understood there are three factors which are directly operative in producing eczema in infants: a, overfeeding with either fat or sugar, or both; b, local irritation; c, anaphylactic idiosyncrasy to foreign proteins, most commonly lactalbumin, egg white, casein, or beef protein. The remedies at our disposal are based generally upon these three factors. He then discusses several different types.

Breast fed infants.—When eczema occurs in breast fed infants it is usually found in fat, well nourished infants who have been grossly overfed on a two or three hour interval. The child usually has also loose, frothy stools and a good deal of gas. The food intake should be reduced a third or even a half, and the nursing interval made four hours. The infant should not be weaned. In many cases it is necessary to give half to one ounce of protein milk before nursing to reduce the fermentation still further. The mother should be encouraged to empty her breasts, otherwise she may lose her breast milk entirely. Occasionally one sees a dry scaling eczema in a breast fed infant who has been receiving insufficient nourishment, the problem then is to reestablish the breast milk and supply the deficiency. In addition thirty grains of sodium bicarbonate may be given daily in the drinking water.

Artificially fed infants.—The problem here is more difficult. In mild cases it is permissible to use full skimmed milk and make up the required calories with barley, granum or groats flour cooked with thirty grains of sodium bicarbonate, while the antiscorbutic and antirachitic factors are supplied by small doses of orange juice and cod liver oil. If orange juice increases the eczema it may be changed to tomato juice or potato water. When the eczema is moderately severe he recommends the substitution of evaporated for plain cow's milk, modified in the same manner as outlined above.

With regard to idiosyncrasy to food proteins, he has obtained gratifying results in a few cases from the removal of the offending protein but plainly feels that he might have obtained just as good results from general dietetic and local measures without the knowledge of the skin tests. Sometimes the test will show a reaction to a food which a breast fed infant has not had, but which has been part of the food of the mother. If the offending protein be omitted from the mother's diet, a decided improvement in the local skin condition sometimes follows.

Local care.—No water should be used until the eczema has disappeared. The infant may be washed with cotton dipped in olive oil. No wool should come in contact with

he skin. Scratching must be prevented. For wet or weeping eczema crude coal tar is almost a specific, spread on with a wooden spatula two or three times a day for three or four days, then allowed to wear off. A bland, protecting ointment is then applied. For the dry and acutely inflamed type he recommends an ointment made of crude coal tar, zinc oxide, and powdered starch, each two drams, and enough vaseline to make two ounces. This is to be applied twice a day. If there is considerable thickening or scaling of the skin the addition of ten grains of salicylic acid to the ounce is beneficial. For dry and rough eczema not acutely inflamed tar is not necessary; bismuth paste or lanolin applied liberally several times a day will be sufficient. For seborrheic eczema, "cradle cap" or "milk crust," the scalp should be soaked in olive oil at night, the scales combed off in the morning, and an ointment of four per cent. resorcin rubbed in vigorously. Once or twice the scalp should receive a green soap shampoo. The resorcin has to be continued for some weeks. Eczema intertrigo about the genitalia and thighs is treated by removal of diapers, keeping the parts exposed to the air in a warm room, the excreta being wiped off with cotton dipped in olive oil, the application of bismuth or tar paste, and the administration of enough sodium bicarbonate to keep the urine alkaline. Elsewhere keep the opposing surfaces apart and dust with zinc stearate. For papular eczema sop the skin over with a thin starch solution, which is allowed to dry, and in the evening rub in tar paste. Repeat several times. For infected eczema ammoniated mercury ointment applied thoroughly over the infected area is indicated. Furuncles should be opened in the usual manner.

Serotherapy in Measles.—H. L. Ratnoff (*Archives of Pediatrics,* October, 1923) follows the Degkwitz technic, giving the prophylactic injections between the second and sixth day after exposure to infection. The blood is obtained by vein puncture, seven to fourteen days after the establishment of convalescence from uncomplicated measles, from children free from tuberculosis or syphilis. The mixed serum from various patients is used either immediately after it has been obtained by allowing the blood to coagulate for twenty-four hours in an icebox, while still in the fresh state, or was preserved in ampoules with one drop of a five per cent. solution of carbolic acid to ten c.c. of serum. The serum may also be preserved by desiccation. Adults give the most potent serum. The immunizing dose is two to five c.c. of serum, which is sufficient to project a child if given four days after exposure to infection. If the administration is delayed to the fifth or sixth day, the dose must be doubled, and after the eighth day, the treatment is of no avail. As a routine, three to five c.c. may be used. To reinforce the immunity, the serum should be injected as late as possible in the incubation period, employing a dose just sufficient to effect temporary immunity. Four weeks thereafter the patient should be reinjected with the intention of augmenting active immunity by increasing the proportion of antigens. Properly employed, this serum therapy is attended by no danger, and has no contraindications.

Symptoms and Treatment of Thymus Hypertrophy in Infancy.—Rowland G. Freeman (*Archives of Pediatrics,* October, 1923) asserts that enlargement of the thymus in infancy and early childhood with characteristic symptoms is not uncommon. These symptoms include holding of the breath, especially with cyanosis, sometimes followed by unconsciousness, stridor, convulsions, or asthma. These symptoms are readily relieved by efficient röntgenotherapy, which should be continued until no thymus shadow is seen, even though the symptoms have been relieved.

Relative Immunity of Infants under Five Months of Age to Infection with Measles.—Charles Hermann (*Archives of Pediatrics,* October, 1923) concludes that infants under two months of age, whose mothers have had measles, are absolutely immune to infection with measles. Infants under five months of age are relatively immune, and a certain number retain this relative immunity up to the months of age. After the ninth month they are as susceptible as older children, and practically all contract the disease on exposure. Artificially as well as breast fed infants enjoy this immunity with a slight difference in favor of breast fed infants. The immune substance are probably chiefly conveyed to the fetus through the placental circulation. There is no substantial evidence that any important part of the immunity is due to the ingestion of breast milk.

Bacterial Infection of the Urinary Tract in Infancy and Childhood.—E. Bellingham Smith (*Lancet,* September 22, 1923) states that acute cystitis due to Bacillus coli alone or to mixed infection of Bacillus coli and streptococci, is generally readily recognized by the dysuria and frequency, and the nature of the infection is readily discovered by the microscopical examination of a catheterized specimen of urine. Acute pyelitis, however, may give rise to some difficulty unless it is always remembered that unexplained fever in infancy or childhood may have its origin in a Bacillus coli infection of the urinary tract. In many of these cases there are few occasions in which the symptoms indicate irritation or inflammation of the renal pelvis or kidney itself. Where there is acute hematuria, the diagnosis of stone, or of rare conditions like essential hematuria or scurvy, will not be made if a simple cultivation of the urine is made and shows the presence of Bacillus coli.

The conditions to be differentiated are: acute appendicitis, typhoid fever, general tuberculosis, meningeal conditions, pneumonia, with or without a complicating empyema or acute otitis media, endocarditis and endemic malaria. The recurrent fever should be differentiated from that occurring in pulmonary tuberculosis, glandular tuberculosis of the abdomen, tonsillitis and that occurring in rheumatic and nervous children.

In certain cases infection of the bladder certainly takes place as a result of the soiling of the vulva by feces and it is possible that a secondary infection of the renal pelvis and kidney results from direct spread, such spread being facilitated by possible inflammation of the bladder, obstruction of the ureteric orifice, and stagnation of urine in the ureter. A number of cases show pyelitis or pyelonephritis as a sole lesion. In these it is assumed that the organisms enter the blood stream and select the kidney as the victim, owing presumably to some lowering of the resistance of that organ. Lastly, there is the lymphatic theory of the spread of infection, one path being by way of the lymphatics of the ureter from the bladder to the kidney, the other being directly from the lymphatics of the large bowel to the lymphatics of the capsule of the kidney.

Effect of Caffeine in Infancy. — Lili E. Herzfeld (*Monatsschrift für Kinderheilkunde,* October, 1923) states that there are pronounced differences in the effect of caffeine, not only between those in adolescence and infancy, but also between normal infants and those previously injured and subsequently hypersensitive to caffeine. Following the administration of 0.2 to 0.3 gram of caffeine sodium benzoate to healthy infants, slight changes in the respiration, the pulse and the blood pressure appear; however, diarrheas and loss of weight are frequently observed. In debilitated and convalescing infants even the usual dose of 0.05 gram of caffeine may occasionally produce these symptoms of toxicity.

The Position of Infantile Nephritis in Modern Renal Pathology.—Leo Mendel (*Monatsschrift für Kinderheilkunde,* October, 1923) is convinced that only the number of the diseased glomeruli indicates whether a focal nephritis or a diffuse nephritis is present. The transition forms of both disease pictures are so fleeting that their differentiation appears to be unnecessary. The author is opposed to considering infantile nephritis as a focal nephritis and as a separate disease entity. He sees another reason for considering infantile nephritis as a diffuse nephritis in the fact that scarlet fever is very frequently the cause of infantile nephritis and the fact that scarlatinal nephritis is the classical case of diffuse nephritis. Consequently the author believes in the possibility of subsequent sequelæ even in cases of immediate apparently benign cases.

Dilatation of the Aorta in Children Associated with Chronic Interstitial Nephritis.—J. H. Sheldon (*British Medical Journal of Children's Diseases,* October-December, 1923) believes that general dilatation of the aortic arch is a possible sequel of chronic interstitial nephritis in children. It may be of sufficient extent to produce the clinical signs of aneurysm, and is capable of causing aortic regurgitation. In two cases reported, the aorta showed very little departure from the normal structure, indicating that the dilatation is probably a mechanical consequence of the hypertension. To a minor degree the condition is probably a commoner one than is usually supposed.

GASTROENTEROLOGY

Elimination of Dyes by the Stomach.—Paul Saxl and D. Scherf (*Wiener klinische Wochenschrift,* September 20, 1923) have found that only the lipoid soluble dyes, such as neutral red and methylene blue, are excreted with the gastric juice. The dyes that are only water soluble, such as indigo-carmin, congo red, pyorrhol blue, and fluorescein, are not excreted by the gastric juice. There is no special localization for the excretion. Dyes do not pass into the interior of the stomach in the presence of complete achylia.

Gastromyotomy: An Operation for the Cure of Chronic Ulcer of the Stomach.—T. C. Clare (*Lancet,* September 22, 1923) recommends gastromyotomy only in the presence of a chronic indurated ulcer of moderate size near the lesser curvature, uncomplicated by hour glass contraction and not adherent to the pancreas. If the ulcer is found to be on the anterior gastric wall, a curved incision, about four inches long and with its convexity downward, is made through the peritoneal layer only below the ulcer and not near indurated tissue. The peritoneum is then reflected for about a quarter of an inch on either side of the incision and the muscle fibres are defined. The incision is then carried down to the muscularis mucosæ and the divided muscle fibres are separated on either side of the incision by gauze dissection, and Lembert sutures are inserted into the peritoneal coat in such a manner that the cut edges of the peritoneum are inverted into the gap in the muscular coat. If the ulcer is located on the posterior wall of the stomach, the latter is exposed through an opening in the mesocolon and the posterior gastric wall is incised; the anterior incision is also made, thereby practically isolating the ulcer as far as the circular muscle fibres are concerned. This operation is the link between medical and surgical treatment, the purpose being to encourage healing the ulcer by diminishing the functional activity and thus resting the stomach. This is accomplished by putting out of action for a time the actual muscle fibres whose contractions irritate the ulcer.

Refractometric Determination of Pepsin in the Gastric Contents.—Emil Reiss (*Schweizerische medizinische Wochenschrift,* March 29, 1923) describes the technic as follows: Ten c. c. of the filtered gastric juice are diluted with an equal amount of one twentieth normal hydrochloric acid, of which mixture one drop is examined in the Pulfrich dipping refractometer (control). One half gram of beef fibrin or an equal amount of coagulated egg albumen is added to the gastric juice to be tested (both in the form of a dry powder) and the mixture is placed into an incubator. If fibrin is used it is reexamined refractometrically after ten minutes and if albumen is used after two hours. The difference in the refraction before and after incubation expressed in divisions of a scale of the apparatus or in units of the refraction index in grams of albumen, indicates the resulting action of the pepsin. Values between 4.5 to 7 divisions on the scale and more indicate a normal average and less than four parts denote a reduction of peptic activity. For exact scientific investigations the same hydrogen ion concentration ($P_h = 1.77$) should be maintained. This is accomplished by comparing a standard solution of $P_h = 1.77$ with the gastric juice mixed with a suitable indicator (crystal violet or thymolsulphthalein). Such amounts of acid or alkali as are required to produce like colors in the standard tube are added to another specimen of gastric juice (without indicator) and the procedure is repeated as described. This technic requires little time and can also be applied to small amounts of gastric juice.

Ileocolic Stasis.—Sidney K. Simon (*Southern Medical Journal,* October 1923) says that much can be accomplished in the treatment of chronic intestinal stasis if the cooperation of the patient is obtained and medical measures are carried out intelligently. The use of stereotyped, printed diet forms cannot be too strongly condemned. The various dietetic idiosyncrasies of the patient should be carefully considered, especially as the diet employed must be persisted in for a long period of time. The basic principle in the dietary involves the substitution of coarse, gritty and fibrous food substances for the bland, easily macerated or digestible variety. Meats and eggs should be greatly if not entirely restricted, since their high protein content furnishes ready pabulum for the more septic types of proteolytic bacteria. The mushy forms of cereals should be replaced by coarser varieties, such as bran, oatmeal and cornmeal. In the same manner the highly milled wheat flour should give way to the ground whole wheat products. Raw fruits and vegetables of all kinds should occupy a prominent place on the diet list. Buttermilk and malted milk, in the main act as better stimulants of intestinal peristalsis than does sweet milk. Sweets, as a rule, are objectionable, chiefly on the ground of their tendency to produce gaseous fermentation, but honey is apt to act as a mild laxative and rarely produces digestive disturbances. An important point frequently overlooked in these cases is the copious drinking of water. Unless special contraindications are present, the patient should be instructed to imbibe freely during the day, starting with two or three glasses upon arising.

Next in importance to diet is the carrying into execution of a well directed plan of abdominal exercises, which should be insisted upon as a regular routine twice a day and persisted in for several months. Abdominal massage may likewise prove useful, but does not yield as good results as properly directed physical exercise.

High colonic irrigations have been found useful by some observers in assisting in the removal of longstanding fecal accumulations in the right colon. In order to prove effective this method must be carried out with painstaking detail according to the plan recently described by Rehfuss and others. Transduodenal lavage has proved a valuable adjunct in many refractory cases.

Satterlee and Cotton mention an autogenous colon vaccine in the treatment of advanced cases of chronic intestinal stasis. The patient is first purged with castor oil and the third stool obtained, which is found to contain the most virile bacilli from the cecocolic region is plated for the cultivation of the colon organisms. The vaccines, thus prepared, are given as a routine every four days in doses of from one hundred to three hundred million. Bassler, some years back, reported success with colon vaccine.

Pharmaceutical products should be made to play an insignificant rôle in the treatment of intestinal stasis. Indeed the daily use of medicinal purgatives should be broken up and the patient should be made to see the logic and necessity of this plan. The salines are especially to be condemned since they liquefy the contents of the bowl and thereby increase the absorbability of the toxic bodies. Where a daily evacuation is not forthcoming at the beginning of treatment a simple tap water enema at bed time is preferable to purgatives. Petroleum oil, though recommended highly by many English authorities, is rarely productive of permanent good and should occupy only a temporary place, if any, in the treatment of intestinal stasis.

CLINICAL MEDICINE

Clasmatocytes and Tumor Cells in Cultures of Mouse Sarcoma.—Warren H. Lewis and George O. Gey (*Bulletin of the Johns Hopkins Hospital,* November, 1923), state that the use of Drew's colloidal calcium embryonic juice medium has given excellent results as a fluid for the cultivation of mouse tumors. Both the tumor cells and clasmatocytes, which were abundantly present in tumor No. 18, migrated out in culture, and their cellular details could be studied separately.

Sodium and Potassium Content of Blood Serum in Various Diseases and of the Cerebrospinal Fluid in Proved and Suspected Syphilis.—Charles S. McVicar and Helen Ross (*Journal of Laboratory and Clinical Medicine,* November, 1923), found that the blood serum of fifty-six patients with various diseases showed an average sodium content of 365 mg. for each 100 c.c. The cerebrospinal fluid of nine patients with syphilis showed an average sodium content of 382 mg. to 100 c.c.; 118 patients with various diseases had an average potassium in the blood serum of 20.7 mg. to 100 c.c., while the average figure for potassium in the cerebrospinal fluid of 117 cases with proved or suspected syphilis was 10.5 mg. to 100 c.c.

Chemical Factors in Fatigue.—Norris W. Rakestraw (*Journal of Biological Chemistry,* May, 1923) subjected nine men to running rapidly up and down stairs for about ten minutes, or until almost completely exhausted. Chemical analysis of the blood following such exercise reveal the following facts: uric acid, although sometimes increasing but slightly following a short period of exercise, continues to increase for some time thereafter. Sugar, increasing decidedly after such exercise, rapidly returns to normal again, and has generally fallen to a subnormal level at the end of an hour and a half. There is a slight tendency for chlorides to increase immediately following exercise.

Comparative Antiphlogistic Effects of Salicylate, Cinchophen, and Neocinchophen in Experimental Edema of the Head and Neck.—P. J. Hanzlik and M. L. Tainter (*Journal of Laboratory and Clinical Medicine*, December, 1923) produced inflammatory edema of the head and neck of rabbits by paraphenylenediamin, in order to study the effects of salicylate, cinchophen, and neocinchophen. The results of their experiments do not indicate that these drugs ameliorated the edema and blood concentration effects of dara in any way, and therefore as antiphlogistics under the conditions of the experiment they were negligible. The beneficial therapeutic effects of these drugs in rheumatic fever appears to be produced neither through etiotropic nor organotropic, but rather through symptomatic action, the benefits being mediated through antipyresis and analgesia.

Studies on the Pharmacology of Sodium Citrate: Circulation.—George R. Love (*Journal of Laboratory and Clinical Medicine*, December, 1923) performed the work reported on dogs under light ether anesthesia. This study brought out the following points: The heart muscle of dogs is depressed by doses of thirty mg. sodium citrate per kilo or more. The vasomotor centre is stimulated by suitable doses of citrate. The endings of the accelerator nerves to the heart are markedly stimulated by large doses of citrate. There is some evidence that large doses cause active dilatation of the vessels of the kidney. Plethysmographic tracings of the extremities and intestines show no peripheral action upon blood vessels. Sodium citrate, in the dose used and at the rate injected in blood transfusions, produces no effect upon circulation which would militate against its use as an anticoagulant.

Letters to the Editor.

THE BANTING RESEARCH FOUNDATION

TORONTO, CANADA, *March 6, 1924.*

To the Editor:

The discovery and development of insulin by Dr. F. G. Banting, Mr. C. H. Best and other cooperating investigators, has brought relief to a multitude of sufferers from diabetes throughout the world. At a low price this boon has been placed within reach of all, but it is well known that only a beginning has been made in alleviation even of this one malady. Notwithstanding the magnificent advances that have been effected in arresting or averting many of the most grievous attacks of disease on human life, mankind is beset by enemies. Their strategy must be discovered and circumvented. This can be done only by patient research conducted in the main by skilled investigators who devote their lives to scientific inquiry. For these investigators the public at large must provide the means of support, for they it is who benefit immensely thereby. Such work has been going on quietly all over the world. Laboratories in the universities have groups of investigators working in cooperation under the direction of competent scientists. But only now and then does a result such as Dr. Banting achieved strike the imagination of the world. It is, therefore, but appropriate that advantage should be taken of it to appeal to the grateful public for support in making possible the continuance and prosecution of this work and of other investigations in medical science. To effect this and to signalize the discovery and the development of insulin, the Banting Research Foundation has been created.

The purposes of this foundation have been defined to be: 1. To provide, in the first instance, further funds for the support of the Banting and Best Chair of Medical Research at the University of Toronto. 2. To establish a fund for the adequate financial support of such scientific workers as may have proposed definite problems of medical research, and for whom funds are not otherwise available. Such assistance may be given to persons working in the University of Toronto or elsewhere.

All financial arrangements in connection with the collection and reception of the principal and subsequent expenditure of the income of the fund have been vested in a Board of Trustees, the members of which are appointed for a term of three years subject to reappointment at the end of their respective terms of office. Trustees have now been appointed as follows: Sir Robert A. Falconer, president of the University of Toronto, chairman; Lieutenant Colonel R. W. Leonard, member of the Board of Governors of the University of Toronto, honorary treasurer; Rev. Canon H. J. Cody, D.D., LL.D., chairman, Board of Governors, University of Toronto; C. S. Macdonald, Esq.; W. E. Gallie, M. D., surgeon in chief, Hospital for Sick Children, Toronto; J. G. FitzGerald, M.D., F.R.S.C., professor of hygiene and preventive medicine, and director of the Connaught Laboratories, University of Toronto; Professor V. E. Henderson, M.A., M.B., professor of pharmacology, University of Toronto; Mr. John W. Rogers.

The trustees propose to make an appeal to the public for funds in the immediate future. In the meantime they desire to bring these facts to your attention and they hope that you will be good enough to communicate them to your readers.

F. LORNE HUTCHISON, honorary secretary.

P.S. Subscriptions to the fund will be welcome at any time and should be made payable to the Banting Research Foundation, Toronto, Canada.

MERCURY IN TREATMENT OF DISEASE

PHILADELPHIA, *March 11, 1924.*

To the Editor:

I have read the article by Dr. Hugh Young, under the title of "The Treatment of Septicemia and Local Infections by Intravenous Injections of Mercurochrome 220 Soluble and of Gentian Violet," which appeared in the *Journal of the American Medical Association* of March 1, 1924, with great interest and pleasure.

That part of it which describes the treatment of several diseases by mercurochrome 220, offers nothing new to the profession excepting the compound of mercury used by him (Young), and his work simply corroborates the work of another, viz., Commander Barton Lisle Wright, Medical Corps, U. S. Navy.

In 1910 Dr. Wright first claimed by publication in the current medical journals of the time, that mercury (Hg) was a superior curative agent in all diseases of vegetable parasitic origin. From then until 1916, he published numerous articles under the title of "The Treatment of Diseases of Vegetable Parasitic Origin by Deep Muscular Injections of Mercury," or similar titles.

His reports embraced very many diseases of such origin. In one paper he described some thirty odd cases of colon bacillus septicemia, and his results in all the diseases mentioned in his reports were as prompt and as brilliant as those described by Young.

I trust that you will publish this letter in your magazine, in order that there may be no misconception among the members of the profession as to Dr. Wright's just claims to priority, based on his original work, as repeatedly published in the NEW YORK MEDICAL JOURNAL and the *Medical Record* between the years 1910 and 1916, inclusive.

J. A. CLOYD, M.D.,
Lieutenant, Medical Corps, U. S. Navy.

PRODROMIC DREAMS

CAMBRIDGE, MASS., *March 16, 1924.*

To the Editor:

In connection with a study I am making of the physical stimuli of dreams, I should be glad to receive from readers of THE JOURNAL instances of prodromic dreams, as Hammond termed them. These are dreams in which the presence of some organic disease, still in its incipiency, is indicated by a dream, or series of recurrent dreams, directly or symbolically localizing the part affected. An instance in point is a personal experience of nearly twenty years ago, in which the presence of a growth in the throat, unappreciated in waking life, was indicated by recurrent dreams of a cat clawing my throat. In the belief that there are many similar cases that only lack reporting—a belief fortified by researches which have already given me an interesting collection of such dreams—and that publication might be of future diagnostic assistance, I now appeal for data to medical men who have had experience of prodromic dreams in the course of their practice. Accounts of these will be gratefully received by me at 2 Riedesel Avenue, Cambridge, Massachusetts.

H. ADDINGTON BRUCE,
Editor, *The Mind and Health Series of Medical Handbooks.*

NEW YORK, WEDNESDAY, APRIL 2, 1924

Medicolegal Notes.

HOSPITAL DEFENDANT'S DEFENCE WHEN SUED FOR BOTH NEGLIGENCE AND BREACH OF CONTRACT.

Where the complaint in an action against a hospital by a paying patient for injuries caused by a nurse alleged breach of contract and also negligence on the part of the nurse, it was held, Klein v. New York Eye and Ear Infirmary, 201 N. Y. Supp. 218, that the defendant was entitled to set up the defence that it is a charitable corporation, conducting a hospital for the cure and treatment of diseases of the eyes, ears and throat, for the benefit of the public, notwithstanding the plaintiff's contention that the gravamen of the action was the breach of the defendant's conduct, and that therefore the plea that the defendant is a charitable institution constituted no defense.

UNCERTAINTY AS TO FUNCTION OF UVULA.

In a malpractice action in which damages were sought for the removal of the uvula of the patient, a girl eight years old, while removing her tonsils, a medical witness for the plaintiff testified that he could not say to what extent the uvula was a necessary organ. The experts testifying for the defendant stated that the removal of the uvula would not be attended by any injurious consequences. All the experts said that it is proper to remove a diseased uvula, and the record showed that a diseased uvula is sometimes found with diseased tonsils.

The North Dakota Supreme Court held, Schmidt v. Stone, 194 N. W. 917, that the rule that expert testimony upon technical matters beyond the training or experience of lay witnesses must, when uncontradicted, be accepted as conclusive by the jury, was not applicable to the facts in this case, since all the experts admitted that much doubt and uncertainty existed among medical men as to the function, if any, of the uvula. "In the absence of evidence to the contrary," the court said, "the law presumes the exercise of a reasonable degree of care and skill by a physician and surgeon, and that the defendant was innocent of wrong. Nor does the fact that defects appeared after the operation or treatment, unless of such a character that negligence must be assumed from their unexpected presence, which is not the case here, constitute evidence of negligence. The maxim *res ipsa loquitur* has no application. Negligence will not be imputed to a physician without evidence or proof thereof."

Judgment for the plaintiff was reversed for a new trial for error in receiving, over objection, evidence for the sole purpose of contradicting answers of one of the defendant's medical witnesses on cross examination, to questions upon irrelevant or immaterial matters, contrary to the rule that such answers were conclusive on the examiner.

MEDICAL OPINION EVIDENCE AS TO PERSONAL INJURIES

In an action for personal injuries, a physician who e amined the plaintiff was permitted to testify that in h opinion plaintiff had suffered a severe concussion of t brain, and that in his opinion the brain conditions he fou upon examination indicated a severe injury to that orga The opinion of the witness was based upon stated fac which included the showing that plaintiff had been render unconscious for five days and nights. The jury had befo it undisputed evidence that he was thrown to the pav street from one of two colliding vehicles whose combin speed probably equalled forty miles an hour and that h head struck the paving or a rail. It was held, Gilchrist Kansas City Rys. Co., 254 S. W. 161, that the opini given was competent because it related to the nature injuries not open to observation by laymen or jurymen, a discoverable only by expert examination.

It was also held competent for plaintiff to ask a medic witness whether any kind of operation would improve ce tain conditions to which he testified, plaintiff having alleg that his injuries were permanent.

The plaintiff, in a personal injury case, on cross-examin tion of an expert medical witness for the defendant, p a hypothetical question to him, based on facts in evidenc and asked his opinion as to whether the existence of suc facts would produce or cause the plaintiff's appendicit and ovarian condition, and he replied, "Well, I think it possible." The Alabama Supreme Court held, Alaban Power Co. v. Bruce, 96 So. 346, that the trial court did n err in refusing to exclude this answer, the question bein relevant and asked on cross examination.

EVIDENCE OF FEAR OF BLOOD POISONING INADMISSIBLE TO MAG NIFY DAMAGES FOR INJURIES.

In an action for injuries to a hand, the trial court per mitted the plaintiff to testify that he had fears of bloo poisoning. The Kentucky Court of Appeals, Louisville N. R. Co. v. Davis, 250 S. W. 979, said, on appeal from verdict and judgment of $3,000, that, while there is a con trariety of opinion on the question, it is the rule in Kentuck that, in an action for personal injuries, one may testify t his mental suffering just as he may testify to his physica suffering. It was not shown that plaintiff's hand becam infected, or that the injury itself was such as might neces sitate amputation. While some courts have gone to the ex tent of holding that the mental suffering for which a recov ery may be had for a personal injury inflicted by the negli gence of another may include the mental worry, distres grief, and mortification which may be shown to exist be cause of the injury, the court knew of no case where th injured party has been permitted to magnify the damages b calling the attention of the jury to fears that were altogethe groundless and never materialized. In view of the size o the verdict, it was held that the admission of the evidenc was prejudicial error, and the judgment was reversed for new trial.

MEDICAL OPINION EVIDENCE AS TO PERSONAL INJURIES.

As a general rule a physician qualified as an expert ma testify as to the probable result of an injury; and the Mis souri Supreme Court holds, Gatz v. United Rys. Co., 25 S. W. 61, that the affirmative answer of a medical exper witness in a personal injury case to the question whethe the condition of the plaintiff's knee was likely to be perma nent did not invade the province of the jury and was no speculative. The same court, in Melly v. Railroad, 215 Mo 567, 114 S. W. 1013, held that the testimony of a physicia was admissible to the effect that plaintiff's injuries woul continue to grow worse and that the probabilities were tha they would be permanent; that such testimony was no conjectural, but proper as bearing on the question of dam ages.

PROOF OF CONTRIBUTORY NEGLIGENCE OF PATIENT

The Georgia Court of Appeals holds, Bryant v. Anderson 119 S. E. 920, that in a suit against a surgeon for damage for a personal injury alleged to have been caused by h malpractice, where the defense is that the injury wa caused by the plaintiff's negligence, and where the plainti makes out a prima facie case by showing that the injur was caused by want of due care, skill or diligence on th part of the defendant, and does not, in making out h case, show any negligence on his own part, the burden on the defendant to prove that negligence of the plainti caused or contributed to the injury.

The Medical Treatment of Duodenal Ulcer*

With a Critical Review of Certain Remedies Employed

WALTER A. BASTEDO, M.D.,
New York.

Duodenal ulcer is not so serious a disease as gastric ulcer and the outcome of its treatment either medically or surgically is more often a satisfactory one. Nevertheless, until the ulcer is healed the menace of perforation, hemorrhage or slow extension is always present. Therefore, if the diagnosis is ulcer let us be unwilling to temporize in its treatment. It would seem almost as justifiable to treat pneumonia as an ordinary cold, or dysentery as a simple diarrhea, as to treat peptic ulcer by the methods employed for a simple functional digestive upset, or to attempt to treat an ulcer by medical means when obviously it requires surgery. Among several cases which have taught us this, we might cite two:

CASE I.—A very nervous man who had been put to bed for an ulcer cure by one of our best gastroenterologists became psychically so upset by his confinement that the physician allowed him to get up and go back to business. In consultation, as his symptoms had entirely subsided under the régime instituted, we sanctioned the procedure. On diet and treatment the man felt perfectly well, so that after four or five months he forgot his sickness and became completely careless in his eating and drinking. Then he had two or three hemorrhages in rapid succession and had to be transfused twice in order to save his life.

CASE II.—A man with penetrating ulcer of the duodenum as shown by x rays, consulted us and we advised surgery. He said, "My business is in such a state that if I leave it now I believe I shall go bankrupt." Under these circumstances we placed him on hyperacidity diet and medical measures which made him feel better than he had for years. After several months of faithfulness to the treatment and almost complete freedom from symptoms his old pain returned with violence, and did not yield to milk diet, sodium bicarbonate and magnesia as it had before. He consented to surgery on Tuesday of one week, arranged to enter the hospital on the following Monday, had a perforation on Thursday night, and was buried on the Monday, an emergency operation having been done. There is a great deal of evidence that some ulcers heal without any special ulcer treatment, but nowadays when we are asked, "Is there an ambulatory treatment for ulcer?" we reply, "Not by us."

In our opinion medical treatment promises to be successful in the majority of cases of duodenal ulcer. It is true that undoubtedly owing to wrong diagnosis some patients are cured medically when they never had ulcer. But we think that this is better for the patient than to discover the error through a surgical hole in the abdominal wall. After surgery, particularly where the ulcer is not excised, medical treatment is also indicated. There are many plans of treatment in use, almost all being modifications of the old French one of administering milk, cream and eggs in small amounts, frequently repeated, together with alkalies. In the hands of skilled practitioners the various plans seem to meet with equally good results, therefore one must not be dogmatic in regard to the merits of one's own particular method.

The objects of medical treatment are to relieve unpleasant symptoms and to provide conditions favorable to the healing of the ulcer while maintaining the patient's nutrition. These objects seem to be attained through rest, diet and certain other remedial measures. In a specific case antiluetic measures must also be instituted.

REST

This is secured by keeping the patient in bed for a period of three or four weeks, preferably in a hospital away from home and family. After this period we allow him to sit in a chair, twenty minutes the first day, and each day thereafter an increasing length of time for one or two weeks; then allow him to walk, increasing the distance each day, but always with the avoidance of even slight fatigue. Until the end of the sixth week or so the patient lies down after each feeding. The length of time before the patient is permitted to attend to his usual affairs is at least two months; the length of time before rules may be abolished is indefinite, but usually not less than a year. The reason for failure of cure is often enough failure to continue the treatment for a sufficient length of time.

Rest is to favor quiet and ease, to prevent body strains, to lessen the food requirement, and by the horizontal position to favor emptying the stomach

*Read before the New York Academy of Medicine, January 19, 1924.

Copyright, 1924, by A. R. Elliott Publishing Company.

and to eliminate gravity drag on the duodenum and stomach. During the whole period a reasonable amount of mental calm favors the cure, and this is sought by light reading, radio apparatus, the exclusion of all but especially desired visitors, and sometimes, in the case of a business man, permitting him to talk business for a few minutes a day with someone from his office. During the bed period, we permit the patient to get up to empty the bowels, either using the bathroom if that adjoins the bedroom, or using a commode in the room. This not only promotes the bowel movements, but also keeps the patient's legs and body in better condition.

DIET

1. Meals are small to allow the stomach to contract, for this tends to lessen gastric hyperperistalsis and pylorospasm with their high prepyloric pressures and the development of organic acids and gas. It also lessens spasm in the duodenum directly associated with the ulcer.

2. Meals are frequent to satisfy the caloric needs of the patient and to forestall hunger pains.

3. Meals are increased by gradual additions, no sudden jumps into heavier diet being permitted.

4. The intervals between meals are lengthened as the complexity of the meals increases.

5. The food is bland, nonirritant, containing no coarse, gritty or fibrous particles, no alcohol, coffee, spices, seasoning, acids, fermented milks, fruit or excessive salt. Unlike Lenhartz, we prefer it not icecold.

In the beginning it seems to us there are no foods better than milk, eggs and cream; but at the outset it is desirable to prevent the normal change of milk to the solid form in the stomach through its coagulation by the rennet ferment. This we accomplish by twenty minutes of peptonization, though the same effect may be obtained by adding one or two grains of sodium citrate to each ounce of milk. After the first week this precaution is not usually taken.

ULCER DIET

If stomach permits, make milk feedings every hour, otherwise every one and one half or two hours. If at the regular time the stomach seems unready for the feeding skip that feeding. Allow water as desired in amounts up to four ounces. Rinse mouth with water after each feeding and allow a swallow of water. Peptonize milk for twenty minutes by the warm method, then quickly bring to boiling point, cool, and keep on ice. Serve food hot or cold as patient may prefer, but not icecold. If eggs are not acceptable substitute two ounces of cream for each egg.

First day: Peptonized milk, three ounces every hour from 8 a. m. to 9 p. m. and once in the night if patient is awake.

Second day: The same, but four ounces every hour.

Third day: One egg in each quart; four ounces every hour.

Fourth day: The same; five ounces every hour.

Fifth day: Two eggs in each quart; five ounces every hour.

Sixth and seventh days: Two eggs and two ounces of cream in each quart; five ounces every hour.

Eighth and ninth days: Plain milk, two eggs in each quart; six ounces every hour.

Tenth day: Plain milk, two eggs and two ounces of cream in each quart; six ounces every hour.

Eleventh day: The same, but at one o'clock, milk toast made with one full slice of toast, four ounces of hot milk and one ounce of cream. Make next feeding two hours later.

Twelfth day: The same, but for one evening feeding a saucer of junket, custard or farina with cream (or milk) and sugar. Make next feeding two hours later.

Thirteenth day: The same, but for the first or second feeding give saucer (four ounces) of oatmeal gruel or white cereal (arrowroot, cream of wheat, farina, hominy, rice), with cream (or milk) and sugar. Make next feeding two hours later.

Fourteenth day: The same, but at one o'clock two slices of toast with hot milk and cream. Next feeding two hours later.

Fifteenth day: The same, but for evening meal, one coddled or soft poached egg, one slice of toast and butter, and junket, custard, or farina with cream (or milk). One glass of milk or water to drink. Next feeding two hours later.

Sixteenth day to end of sixth week:

8 a.m.: Oatmeal gruel or white cereal, one poached, soft boiled or coddled egg, one slice of toast and butter, one glass of milk or cocoa made with milk.

10 a.m.: One glass of milk or milk and egg, or equal parts of milk and cream.

11 a.m.: Same.

1 p.m.: Minced chicken, creamed sweetbread or brain, or scraped cooked beef, one small baked potato with butter, one slice of bread or toast and butter, milk or water to drink. (In the fourth week may add small helping of soups as below.)

3 p.m.: A glass of milk, or milk and egg, or equal parts of milk and cream.

5 p.m.: Same.

7 p.m.: One soft poached egg on toast, or soft boiled egg with toast or zwiebach, and custard, farina, blanc mange, junket, plain rice pudding or boiled rice, with cream (or milk) and sugar.

9 p.m.: One glass of milk, or milk and egg with two plain crackers.

After six weeks:

Breakfast: Oatmeal gruel or white cereal, one or two poached or soft boiled eggs, toast or zwiebach, a glass of milk or cup of cocoa made with milk.

11 a.m.: A glass of milk and egg, or milk and cream.

Dinner: 1. Strained creamed soup or puree (not made from meat stock) of potato, peas, beans, asparagus, corn, celery or spinach.

2. Chicken, squab, lamb chop, beef steak, creamed sweetbread or brain. Meat to be free from fat or gristle and cooked by broiling, boiling or roasting.

3. Baked potato, plain or creamed macaroni or spaghetti, rice, strained peas, beans, spinach, squash or carrots, asparagus tips.

4. Bread, toast or zwiebach, with butter.

5. Milk or water to drink.

4 p.m.: A glass of milk and egg, or milk and cream.

Supper: One egg, toast, zwiebach, or bread with butter, and a dessert (custard, farina, cornstarch, blanc mange, junket, vanilla ice cream, milk and cereal puddings, rice, tapioca, sago).

9 p.m.: A glass of milk, or milk and cream with crackers.

No salt, pepper or other condiment to be served with the food.

There is some evidence to indicate that milk, cream and eggs do not lessen acidity, but it is our belief that it is not by the reduction of acidity that the cure is obtained. If milk causes diarrhea, flatulence, nausea or a feeling of heaviness in the stomach, substitute dried milk, which is frequently well borne by the milk sensitive types. If a milk sourness supervenes lavage the stomach in midafternoon and give a milk free diet for two or three days. Such might include cereal with butter, potato, spaghetti, wetted toast, soft cooked egg and perhaps shredded chicken or scraped cooked beef. As a rule milk sourness means either an unconquerable pyloric obstruction or marked gastric atony. Frequently we have noted stomach discomfort or distention when first feeding cereals, and in this case we omit the cereal for several days.

MEDICINAL AGENTS

In the main these consist of antacids, demulcents, such as bismuth and oil, and laxatives.

Antacids.—Smithies has laid great stress on the frequency with which ulcer occurs without high gastric acidity figures; yet whether the acidities are high or low it is almost universally agreed that pain in ulcer cases may in most instances be overcome or modified by alkalies. In 1917 Dragstedt found that experimental ulcers exposed to normal gastric juice required no longer time for healing and displayed no more tendency to chronicity than did similar lesions in the absence of gastric juice. If the alkalies do not favor healing they should not be administered *ad lib.*, hit or miss. For what purpose then do we employ them? The answer is to overcome or to forestall pain or discomfort. Indeed they are employed for pain or discomfort of almost any kind or degree, the pain of distention, the pain of contraction, pain when the stomach is full, pain when the stomach is empty, pain coming early after eating and pain coming late. They may be employed during the digestive period or during the socalled empty period.

For a proper understanding of this action of alkalies in overcoming pain we must know the origin of the pain; and since the most noticeable pain in ulcer cases is the socalled hunger pain or empty pain we might first inquire as to its causes.

1. *Is the cause the irritation of food?* As this pain usually comes after the food has all passed and is promptly relieved by taking food this would seem unlikely; moreover it may be abolished by what we normally consider irritants, for example, lemonade, orange juice, dilute hydrochloric acid, chocolate soda water, whiskey and beer, and we have had patients who habitually obtained relief from lime drops. Moreover, these pains are not necessarily empty pains, for sometimes in pyloric obstruction cases they occur when there is still plenty of food in the stomach, in which case also they may be relieved by alkalies, other liquids or food.

2. *Is the cause hyperacidity?* It has been shown that at the outset of these pains the acid titre has remained practically unchanged. In one case before the pain Hardt found the acid figures 30 free and 50 total, and during the pain period 35 free and 60 total. He relieved the pains by alkalies, and an hour and a half later when there was no pain found the free acid 65 and total 75. Moreover, as pointed out many years ago by Einhorn, hunger pains occur in cases with complete gastric achylia.

3. *Is the cause pylorospasm?* As shown by the röntgen ray pyloric spasm is frequently present in both gastric and duodenal ulcer without any pain at all, indeed pain at such times is conspicuous by its absence. Also during palpation actual hard contraction of the pylorus may be felt by the examiner without any pain being experienced by the patient.

4. *Is the cause excessive motor activity?* This is greatest during the digestive period when the hunger pains are absent. Moreover, a most noticeable phenomenon is the prompt relief by food which regularly sets up active peristalsis. Homans has shown that intense gastric activity can occur in ulcer patients without giving rise to pain and that the hunger pains are not associated with any recognizable action of the gastric walls.

5. *Is the cause hunger contractions?* These become manifest about the usual time for hunger pains, that is, at the end of the digestive period; and they are checked by food, alkalies, beer, wine and dilutions of hydrochloric acid. Therefore it would seem as if these might be the cause of hunger pains. Yet Crohn and Wilensky in more than three fifths of a group of ulcer cases studied at Mt. Sinai Hospital found both tone and hunger contractions weaker than normal, and remarked that as a rule patients with good and frequent hunger contractions proved at operation to be devoid of an organic lesion. They did not report on the relation of pain to hunger contractions, yet found that in ulcer cases marked hunger contractions were more frequently absent than present. Homans reports an interesting case of duodenal ulcer without adhesions, in which during a period of pain eight hours after food there were low gastric tonus and absence of hunger contractions. When the patient turned on the left side the pain ceased and the hunger contractions began. When he turned on the right side the pain recurred and the hunger contractions ceased.

6. *Is the cause hyperesthesia?* Dundon after a series of experimental ulcers in dogs drew the conclusion that hunger pains in ulcer cases are not due to hunger contractions *per se* but to hyperexcitability of the sensory nerves in the visceral wall. Carlson has a similar idea, attributing ulcer pains to the tension of excessive contractions or to that of normal contractions on hyperexcitable pain nerves. Yet we might ask, if the pains are due to a heightened sensitiveness to muscular contractions, why are they not present during the digestive period when hyperperistalsis is evident?

In the light of all these facts we must feel that the cause of the hunger pains of ulcer is not satisfactorily established, and that as a consequence we do not know how alkalies act in checking them.

Digestive pain, as distinguished from hunger pain, is most frequently due to distention, probably secondary to pylorospasm in some instances, and is also frequently relieved by alkalies. According to a number of investigators, noteworthy among whom is Crohn, alkalies given before meals or in the early digestive period tend to induce a more than compensatory high acidity, and sodium bicarbonate more than magnesia. In fact from the experimental work one would almost be persuaded to confine one's prescription for alkalies in the digestive period to subacidity cases, were it not that large clinical experience suggests otherwise.

Of one thing we can feel satisfied, that is, that in ulcer cases the relief of hunger pains and distention pains by alkalies is not due merely to acid neutralization, and their relative values cannot be determined by their power to neutralize acids. The alkalies most commonly employed are sodium bicarbonate, light and heavy magnesia, milk of magnesia and chalk. There are a number of ulcer cases which do admirably with no alkali at all, and there are many that obtain great comfort from the alkalies. In the method of frequent feeding it would seem entirely superfluous to give them after each feeding. Our own practice is to administer about sixty grains of sodium bicarbonate, one level teaspoonful, in a glass of water the first thing in the morning, and milk

of magnesia half an ounce to one ounce the last thing at night, the amount of the latter being determined by the need of the bowels. We do not give alkalies during the day unless the diet fails to control the pains, in which case we give sodium bicarbonate or a mixture of sodium bicarbonate and light magnesium oxide. We believe it unwise to keep the urine continuously alkaline, and if we find it so, lessen our alkalies regardless of symptoms. Should the pain come in the night we have a glass of sodium bicarbonate solution kept alongside the bed to be taken at once. We do not find any disadvantage from the liberation of carbon dioxide from sodium bicarbonate, in fact, we feel that not infrequently the carminative action of this gas is advantageous. Indeed we sometimes add peppermint to our alkali for its carminative effect. Almost never do we employ calcium carbonate, as we find constipation the rule.

Bismuth.—We occasionally employ bismuth, preferring, on theoretical grounds, the amorphous bismuth subcarbonate to the hard crystalline bismuth subnitrate, though practically there is no good evidence of any noticeable difference in their effects. Years ago when performing pharmacological experiments with dogs we would now and again give a meal mixed with carmine stained bismuth subnitrate. On killing the animal one, two or three hours later we regularly found the stomach and the greater part of the small intestine more or less uniformly coated with a light flocculent protective bismuth layer, but never in any case did we find any bismuth at all clinging to the wall of the duodenum from the pylorus to about the papilla of Vater. This region was always swept clean. So we think that bismuth salts are more adapted to the treatment of gastric than duodenal ulcer, though possibly their value in lessening gastric hypersecretion may justify their use even in duodenal ulcer.

Olive oil.—This has been much used by the German school apparently with good results. We do not employ it.

Laxatives.—During the first week or two we administer one half or one ounce of milk of magnesia at bedtime, and an enema each morning if the bowels fail to move by ten o'clock. After this period, if the magnesia movements are unphysiological, as is so frequently the case, we shift to nightly doses of cascara, phenolphthalein or an aloin, belladonna and strychnine pill, if required. Once a week for thorough cleansing we give a dose of castor oil, or calomel followed the next morning by two ounces of milk of magnesia. The diet lacks roughage and a cure cannot be expected unless the bowels are kept adequately working.

Iron.—If the anemia is severe we use transfusion. If it is only moderate we may give hypodermics of iron cacodylate or soluble iron citrate, or small mouth doses of some bland iron preparation such as ovoferrin. As a rule we do not use any iron medication.

Atropine and belladonna.—These drugs seem to be employed extensively with the idea of counteracting hypersecretion and muscular spasm. We have been severely attacked for our statement on several occasions that "in the doses usually employed or permissible for any length of time atropine and belladonna are wholly without effect on the secretory or the motor functions of the stomach." In a recent study of human cases Lockwood and Chamberlin of Detroit, using the fractional method of stomach analysis, found it impossible in doses compatible with safety to demonstrate the marked action of atropine obtainable on the lower animals. Their experiments and results were as follows:

1. One fiftieth of a grain of atropine sulphate in one ounce of water through the tube just preceding the Ewald meal—two pyloric ulcer cases and a normal: effect very slight if any.

2. One fiftieth grain by hypodermic injection just before the meal—two pyloric ulcer cases and one duodenal; moderate reduction in acidity with slight retardation in emptying.

3. One fiftieth grain by hypodermic injection one hour preceding the meal—nine psychopathic subjects free from digestive diseases; moderate reduction in acidity and little or no change in emptying time.

4. One one hundredth grain by hypodermic seven hours before and again immediately before the meal—one ulcer case and two normals; moderate reduction in acidity, emptying time virtually the same.

5. One c.c. tincture of belladonna four times daily for three days—three nondigestive cases; moderate reduction of acidity. All showed symptoms of belladonna poisoning. One c.c. of the tincture of belladonna contains 0.3 mg. (1/225 grain) of total alkaloids.

6. Patient with prepyloric ulcer and moderate obstruction, on feedings of three ounces of ten per cent. cream every two hours. Three experiments: *a.* One fiftieth grain atropine sulphate in half an ounce of water through the tube just before the cream. Same dose repeated with the next cream feeding two hours later. *b.* After two days 1/100 grain hypodermically with the cream, repeated two hours later. *c.* After two more days 1/50 grain by hypodermic with the cream, repeated two hours later. A study of the curves obtained shows that after cream alone and when cream alone was given two hours after the last dose of atropine the acidity distinctly rose, while after the cream and atropine the drop in acidity was marked for the first hour in each case but rose high again by the end of the second hour. After the last experiment the patient had dilated pupils and a very dry throat.

Crohn's experiments of several years ago were even more unfavorable to atropine. The experiences of röntgenologists as expressed to me verbally further indicate that it is only occasionally that ulcer spasm is allayed by a hypodermic of one fiftieth grain of atropine sulphate.

Recently, for painful gastrospasm in ulcer one of our Western colleagues has strongly advocated five to fifteen drops of the tincture of belladonna three to six times a day. The largest of these doses, fifteen drops, represents at the outside seven and a half minims (still less if dropped from the average medicine dropper) which contains of total alkaloids one four hundred and fiftieth grain. This amount would also be represented by three sixteenths grain of the extract of belladonna (the usual dose prescribed is one tenth or one eighth grain). Does anyone here think for a moment that one four hundred and fiftieth grain or much less of belladonna alkaloids is going to overcome painful spasm in an ulcer case? As a matter of fact the doses which

will produce effects are poisonous doses. We therefore repeat our opinion that *"in the dose usually employed or permissible for any length of time* atropine and belladonna are wholly without effect on the secretory and motor functions of the stomach." The drug should be excluded from our plan of treatment, for the effect of belladonna in an ulcer case is purely psychic (in the physician's mind).

Distention usually means pylorospasm with gastric fermentation. Its beginnings should be watched for by frequent percussion of the stomach. It may be relieved temporarily and sometimes permanently by heat to the abdomen, sodium bicarbonate and peppermint, lavage or a cathartic. In a number of cases we have had distention on beginning cereals in the diet, so that for a day or two it has been necessary to feed the patient less often and to omit cereals, or even to go back several days in the diet scheme. But not infrequently on examination the gas and discomfort complained of are found to be colonic and not gastric, when relief may be procured by an enema or by a daily colon irrigation.

Nausea or vomiting is unusual. That from intolerance to food arouses suspicion of gastric ulcer. That from hyperacidity is met by large doses of alkalies. That from retention means pyloric obstruction. That of sour milk requires lavage and a milk free diet, and perhaps a revision of our judgment as to the continuance of the medical treatment.

Night pain is treated by a dose of sodium bicarbonate or magnesia and sodium bicarbonate. If it occurs every night we have the patient awakened shortly before the usual time for its appearance and given either a drink of milk or a dose of alkali, or sometimes we exclude food after 8 p. m. and give codeine one half grain at 9 p. m. This is rarely necessary beyond three or four nights.

Tobacco is not favored, but for obvious psychic reasons is allowed in some cases.

Focal infection is sought in every case and tonsils, teeth and other infectious foci attended to.

SUMMARY

Our ulcer treatment includes rest in bed for three or four weeks, preferably in an institution away from home and the family, few visitors, diversion, permission to visit the toilet, and a diet beginning with peptonized milk and the gradual addition of eggs, cream, toast, cereal, custard, farina, potato, milk and cereal puddings, vegetable strained soups, vegetable purees, certain strained vegetables and ice cream. The meals are small and frequent and not given ice cold. It is our belief that it is not by the direct neutralization of acid that the cure is obtained, yet alkalies are administered in moderation, as sodium bicarbonate and milk of magnesia, or as a mixed powder of sodium bicarbonate and light magnesium oxide, with or without peppermint. We do not employ olive oil or belladonna, and never use lavage as a routine. Duodenal feeding we consider an unnecessary trouble, and rectal feeding superfluous. The treatment is assumed to take a long time and no dietary indiscretions are permitted under at least a year. Under this régime most patients lose their pain and discomforts in one or two days and enjoy an uneventful freedom from symptoms during the treatment and afterwards. Those that do not, if their symptoms are not readily amenable to treatment, are transferred to the surgeon.

A Case of True Pneumotyphus with Submaxillary Abscess

E. C. FOLLETT, M.D.,
Washington, D. C.

The rarity of cases of true pneumotyphus warrants the report of a rather exceptional case observed during the recent epidemic of typhoid fever in the town of Woodland, Me. The case was further complicated by the development of a large submaxillary abscess.

REPORT OF CASE

Case.—J. B., female, aged seven, was seen first on July 28th. Her past history was unimportant. Present illness began five days previously, with sudden onset, a chill, pain in right side of chest, cough, and fever. The patient had not received antityphoid vaccine. Temperature ranged from 102.4° to 104.2°; pulse 110 to 115; respirations 25 to 50. Face was flushed, eyes bright, lips dry, breathing labored and painful, and the patient appeared very nervous. Respiratory movements were markedly restricted on the right side. The patient appeared to be very weak. There was marked dullness over the right lung up to the level of the midscapular region behind. The breath sounds were harsh, with a few fine râles at the end of inspiration; bronchial breathing over the entire consolidated area. There was no expectoration. Blood: leucocytes, 14,500; differential, polymorphonuclear, 78 per cent.; lymphocytes, 18 per cent.; endothelials, 3 per cent.; eosinophiles, 0.5 per cent. The urine was negative.

A provisional diagnosis of lobar pneumonia was made, but owing to the fact that we were in the midst of a typhoid epidemic a Widal test was taken, which was positive, as was also the blood culture, and a diagnosis of typhoid fever was made. The spleen was not enlarged.

In the latter part of the second week a tense, hard swelling appeared in the right submaxillary region; this caused considerable pain and suppurated. It was necessary to open the abscess and about thirty c. c. of thick creamy pus was obtained. Stained smears of the material showed many pneumococci, some fibrin, and many pus cells. The pneumococci were not typed, but were judged to be consistent with type III. The patient obtained immediate and great

relief from the operation, the breathing was much easier, the temperature dropped from 103.2° to 101°, and her color was much better.

The right lung began to clear on the tenth day, although the temperature remained high until the end of the fourth week and fell by lysis. The patient made an uneventful recovery, the lung being absolutely clear at the end of the sixth week and the stool negative for Bacillus typhosus.

The treatment was dietetic and supportive, the Shattuck enteric diet being used.

COMMENT

In a case such as this it is very difficult to say whether there is typhoid fever with early disease of the lungs or a usual lobar pneumonia followed by typhoid fever. It was especially difficult to determine in this instance, as we were in the midst of an epidemic.

This case is similar to that reported by Herrman (1), our case being further complicated by unilateral submaxillary abscess. Osler (2) reports only three cases in his series in which lobar pneumonia was present in the beginning of typhoid fever, and but four cases with submaxillary abscess, in three of which the patient died.

Klein and Torrey (3) have reported a case of lobar pneumonia where the fever persisted after the lungs had cleared. The Widal was positive for paratyphosus bacillus.

Of the fifty-one cases of typhoid fever in the Woodland epidemic this was the only one beginning with typical lobar pneumonia and in which a submaxillary abscess developed.

Bronchitis and Its Treatment*

SIR JAMES BARR, C.B.E., D.L., LL.D., M.D., F.R.C.P., F.R.S.E.
London

In England and Wales during 1922 the death rate to the million of population from the four principal diseases was as follows: Cancer, 1,229; tuberculosis, 1,121; bronchitis, 1,073; pneumonia, 1,073. Since 1921 capillary bronchitis has been placed under the head of bronchopneumonia, otherwise bronchitis would have come more closely to tuberculosis. If we were dealing only with the adult population then the incidence and death rate from cancer would be a long way ahead of all other diseases; no wonder that we have a thriving cancer industry, and are a long way from the solution of the problem.

Chronic bronchitis is a long drawn out disease which causes much misery and suffering, both directly and from its complications; consequently from the point of view of the public its prevention is of much more importance than its treatment. Sir Douglas Powell pertinently says that, "It is impossible truly to comprehend the manifold incidents and conditions of such diseases as asthma, emphysema, pleuritic effusion, pneumothorax, and many other chest maladies without a working knowledge of the static and dynamic conditions of respiration in health." I have dealt so fully on many occasions with the physics of the chest in the pages of the *British Medical Journal,* the *Lancet,* the *Medical Press and Circular, American Medicine,* and the New York Medical Journal that it will be quite unnecessary to enter minutely into the subject here, but I hope to point out some ultraphysical facts which concern those in health as well as those suffering from bronchitis.

The main objects of respiration are to oxygenate the blood and to carry away the effete carbonic acid, and we shall therefore take a brief glance at the anatomy and physiology of the lungs. Sir Douglas Powell says, "Down to the diameter of one mm. the bronchial divisions are possessed of cartilages and a muscular coat, are lined by a ciliated epithelium, and are furnished with mucous glands. The arterial supply is thus far derived from the bronchial artery, the capillaries of which terminate in the bronchial veins, forming a part, therefore, of the systemic circulation. Below one mm. the bronchioles have neither cartilage nor mucous glands, but their muscular coat and the elastic fibres persist, and ciliated epithelium still lines the tube, although soon to give place to flattened nonciliated cells. The arterial supply, still derived from the bronchial artery, terminates, however, in the pulmonary venous capillaries, and forms, therefore, a part of the pulmonary circulation" (1). The alveoli, about 0.25 mm. in diameter, are composed mainly of a framework of fine fibrous tissue with numerous elastic fibres, they are lined by delicate flattened epithelium, and are surrounded by a network of capillaries.

It is a wise provision in Nature that the nutritive vessels of the lungs belong to the systemic system, otherwise nearly every case of red and grey hepatization would be followed by gangrene of the lung. In cases of pulmonary apoplexy or thrombosis the blood effusion is into the alveoli and bronchioles of certain lobules, as first pointed out by the late D. J. Hamilton (2), and not a plug in a branch of the pulmonary artery.

The exchange of gases takes place in the alveoli whether by the ordinary process of diffusion, or this augmented, as suggested by Haldane, Douglas, and others, by a secretory activity of the epithelium lining the alveoli. As the carbonic acid tension in the blood is always represented by that in the alveoli

*Delivered before the Huddersfield Medical Society, January 9, 1924.

t is customary in cases of acidosis and disturbances n the basic metabolism to examine the alveolar air. Various elaborate processes and instruments have been devised for the purpose. You can arrive at a clinical conclusion much more easily by making the patient take two or three deep respirations, and then hold the breath as long as possible; if he can stop breathing for forty seconds you need not trouble further about his carbonic acid tension. In estimating he respiratory capacity of an individual a spirometer s of much more value than a stethoscope.

ETIOLOGY AND PREVENTION OF BRONCHITIS

A chill due to exposure was formerly looked upon as the forerunner of many ailments, and consequently was treated with the respect due to a progenitor, but n modern days this agent has been supplanted by microorganisms, and the chill is placed in a subservient place as a mere predisposing factor. However, any agent which prepares the soil for the ubiquitous microbe is a factor which should not be neglected. It is with the object of prevention and, when not prevented, with the object of obviating the dire effects of this insidious malady that I shall approach the subject.

Heredity plays a very important part. We owe not only our health and intelligence, but too often our tendency to disease to our parents; as Professor Arthur Thompson says, what children die of is their parents. Those who have a hereditary tendency o any catarrhal or arthritic condition should be very careful in their mode of life, and pay special attention to the state of their digestive organs. Any hereditary tendency is easily accentuated by bad hygienic surroundings.

The modern conception that bronchitis is an infective disease due to a multitude of organisms rather han a specific one, or perhaps to some filter passing germ, has modified the former methods of treatment —poultices and expectorant mixtures have given place to vaccines, autogenous and blunderbusses; still we are no nearer a solution of the problem of prevention and cure of the malady.

Specialists dealing with the nose, throat, sinuses, onsils, and teeth say that bronchitis is merely a econdary disease, due to the infection travelling lownwards. This unreasoning attitude is being carried too far; all the pathogenic flora which inhabit he upper air passages are common in warm, dry limates, but bronchitis is rare. The pneumococci affect the alveoli readily enough but they do not rest n their passage down the bronchi; enteric fever is requently associated with bronchitis, but the Bacillus yphosus passes from the blood into the alveoli. With he exception of certain specialists every one recognizes a primary bronchitis and as every one is a specialist on that disease, so in vain will throat and nose nen try to snatch bronchitis from the purview of he general practitioner. You can easily retaliate by nvading their territory; adenoids, tonsillitis, pyorhea, etc., are all easily prevented.

A chill due to exposure is undoubtedly an etiological factor in the causation of bronchitis, but you must clearly understand what you mean by a chill; a cold, dry, still atmosphere much below the freezing point cures the bronchial catarrh often associated with tuberculous disease of the lungs. It is a cold wind with a moist atmosphere which chills you to the bone, and finds out the weak spots in your economy. When a person is feverish or well supplied with internal fuel he can stand much external cold. There are on record cases of typhus fever in which the patients in their delirium escaped from the hospital, and after living for some days in the open without food or clothing recovered. It is quite another matter when the internal temperature is subnormal, and the vital powers depressed from any cause.

When the vital resistance is lowered, and especially during sleep when the controlling influence of the nervous system is partially suspended, the individual is much more liable to the catarrhal effects of cold, hence bronchitis is much more frequent and fatal in the very young and the very old than in adults. In this cold, damp climate many aged persons contract a fatal bronchitis in bed. I have seen a patient suffering from bronchitis, with edema of the lungs and the socalled death rattle in his throat, rescued from death by rapidly raising the temperature of his bedroom with a blazing fire.

Dry air is a bad conductor of heat, hence a dry, still atmosphere, no matter how cold it may be, cannot do much damage to the bronchial tubes. Of course, the dryness of the atmosphere is a relative term, as the amount of watery vapor which it can hold will largely depend on the temperature; if, therefore, a cold atmosphere is not to do any harm, the amount of moisture which it holds should be a long way below the saturation point. The more saturated the atmosphere the less it will take up of the watery exhalations from the lungs, and there may be even a condensation in the bronchial tubes, hence the supersaturated atmosphere of a greenhouse soon becomes almost suffocative, while you can breathe freely in the higher temperature of a Turkish bath. It is, therefore, the excess of moisture rather than the coldness of the atmosphere which works mischief, yet, strange to say, some physicians still continue to use the bronchitis kettle.

In the cold dry climate of Canada and Switzerland bronchitis is much less common than in the moist and comparatively mild climate of this country. With nasal breathing there is not much danger of any degree of dry cold damaging the bronchial tubes. I have seen myself perspiring freely while climbing in the Alps when the temperature was minus 30° C. There can be no doubt that sudden variations in temperature do injure the body; the intense cold of liquid air will as effectively kill the part with which it is kept in contact, as a red hot poker. What we have to do is to protect the body from the injurious influences of the abstraction of heat by a cold moist atmosphere, especially when in rapid motion.

The natural protection arises from the reflex action of the nervous system preventing any rapid loss of heat, but the nervous system is not always on the alert, and its regulative mechanism is not always sufficient to meet the contingencies arising from the sudden changes in, what a friend of mine calls, "this beastly climate." In the young and aged much greater protection than that afforded by the nervous system is required.

Rossbach (3), after the application of cold to the skin, saw the bloodvessels of the trachea contract reflexly after one to two minutes; this was soon fol-

lowed by a venous hyperemia, and an increased secretion of mucus. Personally I cannot place my bare foot on a cold stone without bringing on a sharp attack of sneezing, often followed by watery secretion from the nose, and massage of one foot brings on a sharp pain about the stylomastoid foramen of the opposite side of the body. I have no doubt, therefore, that the decussation of the sensory nerves in my spinal cord is quite normal. I adopt a hardening process by a cold douche every morning summer and winter, and the nearer the temperature of the water to the freezing point the better. I cannot afford to be ill, and I have no wish to contract bronchitis with all its concomitant evils. The hardening process is excellent when judiciously carried out, otherwise it may be a rapid Darwinian method of getting rid of the unfit; but you have to deal with the fit and the unfit, chiefly the latter in this C3 population, so be careful in the application of your methods of prevention. Apart from any respiratory effects long continued cold is apt to give rise to local asphyxia and enlargement of the hands.

In studying the causes of colds the electrical condition of the atmosphere and of the individual is not usually taken into sufficient account. Lord Frederick Hamilton (4) has placed it on record that often in Canada in the winter the air is so dry that you can sufficiently charge yourself with electricity by rubbing your feet along the carpet to be able to light the gas by the sparks from the tips of your fingers. In such an atmosphere you have a dry skin, the electrical condition of your body is good, and you do not contract bronchitis. In this country you should be careful not to have your electricity leaking out through damp boots more quickly than it is generated.

Concussion between the fourth and fifth cervical, and on the second dorsal vertebræ, gives rapid relief in bronchial asthma by relaxing the bronchial spasm, and allowing the lung to contract, but this requires a little care in manipulation as the easiest position to concuss is with the head bent forwards, but this is the worst position for the patient as it interferes with the free entrance of air. It is easy to find the hollow above the fifth cervical spine, and the method which I adopt is to allow the patient to hold his head up, place a large cork about one inch in diameter over the interspace, and it also impinges on the fourth and fifth spines, give the upper end of the cork thirty gentle taps with a small mallet about an ounce and a half in weight, then give thirty taps over the second dorsal spine; after a minute repeat the series, again wait a minute and repeat the series a third time; this if properly carried out should give immediate relief. The lung reflex of dilatation can be readliy effected by friction, and by concussion of the third to the eighth dorsal spines. It is useful in atelectasis and in congestion of the lungs, but in asthma and bronchitis it is more a question of getting the air out of the lungs than of getting it in.

When cold has damaged the mucous membrane and caused some shedding of the epithelium of the bronchi, the inflammatory reaction is readily maintained by the numerous microorganisms which infect the upper air pasages, and by dust, hence the necessity for a clean mouth and nose and a pure atmosphere. The streptococci, pneumococci, staphylococci, the influenza and diphtheritic bacilli, the Micrococcus catarrhalis, and numerous other pathogenic bacteri are often active on the mucous membrane. Measle are usually associated with bronchial catarrh. In th majority of cases of enteric fever the Bacillus typho sus find its way into the alveoli and bronchioles, an sets up a low form of congestive bronchitis especiall in the lower and posterior aspects of the lungs. Th bronchial mucous membrane, when intact, is not good culture field for microorganism, which ar brushed out by the ciliated epithelium; at any rat it is chiefly the minute divisions and alveoli which ar attacked by the tubercle bacilli, the pneumococci, an other organisms.

Various irritating dusts set up and maintain in flammatory reaction, and during the war we had large experience of the destructive effects of poison ous gases on the bronchial mucous membrane.

Gout and other constitutional disturbances ar credited with the production of bronchitis, but suc are not likely to lead to the usual type of chroni bronchitis. In mitral stenosis there is overloadin of the pulmonary circuit, and we frequently get congestive bronchitis affecting the alveoli, infundibulæ and small bronchioles, the blood supply of which belongs to the pulmonary circulation, but in the early stages the bronchi escape as their circulation belong to the systemic system, and the venous blood is returned by the azygos vein to the right side of the heart. In chronic kidney disease acute pulmonary edema is not at all uncommon, but a true bronchiti is rather rare.

Arbuthnot Lane thinks that most of the ills t which flesh is heir are due to the absorption of intestinal toxins, and bronchitis may be included i this list, as the breath of some people suffering fro intestinal stasis is most offensive. Some surgeon and anesthetists seem to become partially immune t ether, but they persist, perhaps unconsciously, i disturbing the more refined sensibility of thei friends. Chronic alcoholism is a common cause o chronic bronchitis, but it does not act as an irritan in its excretion otherwise it would be the alveol which would be primarily affected. It causes a vaso-motor paresis of the bronchial arteries so the bronchi, trachea, larynx and throat are first involved a these organs are supplied by the systemic bloodvessels. Alcoholic bronchitis is an active rather than a passive hyperemia, which by inducing cough leads on to emphysema. Tobacco tends to raise the blood pressure, and there is also the direct irritation of the smoke which maintains a chronic cough, the forerunner of emphysema.

In carbolic acid poisoning, where the irritation arises during excretion, we get a capillary bronchitis or congestive pneumonia.

THE RESULTS OF BRONCHITIS.

Vesicular emphysema is one of the worst results of chronic bronchitis. During coughing the intrapulmonary pressure is raised often 100 mm. of mercury above that of the atmosphere, this subjects to a great strain the portions of the lungs which are not well supported, such as the apices, the margins, and the bases. In the Valsalva experiment the intrathoracic pressure may be so great as to prevent any blood entering the chest, and hence, after a few beats of the heart, there may be so little blood pass-

ng through the lungs that the pulse disappears at the wrist. This experiment is too short to do much mischief.

In ordinary breathing the negative pressure in the chest is only about seven to ten mm. of mercury, but in aiding the circulation this is a constant force which in deep breathing may be readily augmented to about thirty mm. of mercury. In Müller's experiment I have often produced in my own chest a negative pressure of eighty mm. of mercury, and in Valsalva's experiment a positive pressure of 100 mm. of mercury. It is only with healthy lungs that these pressures can be established, and such can do no harm, though I have often had difficulty in persuading students to that effect. Healthy hearts and lungs do not cease working on slight provocation.

ELASTICITY OF LUNGS

The elasticity of even healthy lungs is not great, but it is quite sufficient for all the purposes it is called upon to perform. In fact, I can quite see that if it were much greater there would be a constant danger of producing pulmonary collapse.

In my Bradshaw lecture I showed that in exhausting diseases, where there was not much demand for oxygen, even a whole lung might collapse. The first experiments on the elasticity of the lungs were carried out by Carson of Liverpool at the beginning of last century. He and Robert Bickersteth were also the first to produce pneumothorax in the treatment of phthisis.

In advanced emphysema the chest is filled to its utmost capacity, the elasticity of the lungs is lost, the recoil of the chest walls, and with it the negative intrathoracic pressure disappears. Hence the blood has to be driven into the chest by the left ventricle, and carried through the lungs by the hypertrophied right ventricle. With the abolition of the elasticity of the lungs their free play is lessened or abolished, and the vital capacity which then chiefly depends on the diaphragm may fall to a fourth or less of the normal.

You can thus see that every attack of bronchitis leaves in its trail a gradual lessening of the function of the lungs, and renders the vital resistance less and less to every acute illness.

Asthmatics and bronchitics try to enlarge the chest to get air in, but if they were only taught to drive out a little of that already in there would be no difficulty in inspiring a little fresh air to replace that displaced. In bronchitis and more especially in asthma the difficulty is not in inspiring, but in expiring.

Rigid chest walls lessen the free movement of the lungs, aggravate the mischief and increase the emphysema. If you wish to keep your lungs healthy, and free from emphysema, you must keep your chest walls pliant, and give your lungs plenty of exercise; the more their elasticity is exercised the longer it will last. Costal breathing is much more effective than diaphragmatic. If people were only taught to breathe with the thorax, Nature would look after the diaphragm. The lesson to be learned is keep your thorax moving and for this purpose there is no better form of respiratory gymnastics than hill climbing. The free movement of the chest walls lessens the liability to rigidity of the costal cartilages, but if there is too much lime in the system it is also well to use decalcifying agents.

TREATMENT OF BRONCHITIS.

A large number of cases of acute bronchitis could be aborted or cut short by a clear recognition of the conditions with which you have to deal, and their prompt and energetic treatment. When a person after a severe chill has some distress in breathing he should have a warm mustard bath, be put to bed in a warm room, and if he still feels chilly have a glass of hot punch. A conscientious teetotaller can have a bowl of hot gruel, but as a rule teetotallers do not object to punch so long as it is prescribed as a medicine—the only danger is that they may be getting a chill too often. After this they should have no food for twenty-four hours, but may have plenty of hot water. He can have a Dover's powder, or Sir Archdall Reid's universal panacea of Dover's powder with aspirin and phenacetin. The following morning he should have a saline purge and then remain in bed for two or three days on a starvation diet.

Unfortunately, a medical man does not always get the opportunity of adopting this prompt treatment. A not infrequent sequel is as follows: The person after a severe chill treats it lightly as he thinks he has often done before, goes home, tries to warm himself, attempts a heavy dinner or a late supper for which he has no appetite, goes to bed, passes a restless night, dreams of the deluge or some personal catastrophe, wakes up with a violent palpitation of the heart, and is afraid to go to sleep again for fear of a recurrence of the dream which invariably takes place. The following morning he is exhausted and feeling very ill, he sends for the doctor who correctly diagnoses the case as congestion of the lungs, and as there is little or no rise of temperature he hesitates to use the word pneumonia. The following day he is still worse, bubbling râles are heard all over lungs, a consultant is called in who pronounces the ominous word bronchopneumonia, but assures the relatives that although the case is serious it is not by any means hopeless. The consultant may be tempted to prescribe an expectorant mixture with iodide of potassium, and perhaps a vaccine; the fate of the patient is then sealed, and he dies about the third day from acute suffocative edema of the lungs, or if you like, capillary bronchitis, though that name will not now suit the Registrar General.

The pneumococcus is not such a virulent organism as to kill in a couple of days, even the pneumonic plague would scarcely act so rapidly. As a matter of fact, the pneumococci play a small part in these cases, and the pneumococcal vaccine is of no use.

In these cases where the lungs are waterlogged the action of the sympathetic is very defective, and that of the vagus too great, hence the patient should have an intravenous injection of one fiftieth grain of atropine and five to ten minims of adrenalin solution (one in 1000), in normal saline every two hours until the danger is past. You may make the patient very uncomfortable with the atropine, but there is not much risk of poisoning him. In these cases there is practically always a deficiency of free calcium ions in the blood, hence two or three grains of soluble hypophosphite of calcium should be added to each injection, and a liberal supply given by the mouth—though you cannot be sure of its absorption.

The atmosphere should be warm, about 70°F., and as dry as possible—large amounts of dried calcium chloride, or strong sulphuric acid should be placed in soup plates about the room to absorb the moisture from the atmosphere. There is no need for food, and the quantity of fluid should only be sufficient to moisten the lips and mouth. Some men, who ought to know better, still recommend bloodletting in these cases in order, as they foolishly imagine, to relieve the right side of the heart, but it only removes blood from the systemic circulation and hastens the end.

Chronic bronchitis may follow an acute attack, but this is not the usual course; you are more likely to get many acute attacks during a chronic course. We have said a good deal about the prevention of this disease, and I now merely wish to emphasize these points. Every person with a liability to bronchitis should forswear the use of alcohol in all its forms. It is a frequent cause of the disease in the chronic form, and its regular use is of no benefit in the treatment.

These patients should be hardened and protected against the injurious influence of cold, damp, dust, microorganisms, irritating gases, etc. A pure, dry atmosphere is the best, but if the patient be not particularly vigorous, or have a low vital capacity then the atmosphere should be warm and dry, and the place at an elevation not greater than two or three thousand feet above the sea level. In fact, this is a disease for millionaires, but the ordinary mortal who cannot move about with the swallow, and it is with such that you have mostly to deal, should avoid contracting chronic bronchitis. It is a very troublesome, uncomfortable and long drawn out disease. I have before pointed out the necessity of keeping warm, dry feet, the clothing should be warm but not such as to produce perspiration. In bronchitis associated with any infectious disease the treatment is symptomatic. In typhoid fever the patient should not be allowed to lie too long on his back, and friction by stimulating the lung reflex of dilatation prevents collapse of the lung. Friction is also useful in the congestive type associated with mitral stenosis. In intestinal stasis a brisk purge and antiseptics do good.

Thin, spare, wiry individuals are not only less liable to bronchitis but more easily treated.

Diet.—The carbonic acid is excreted by the lungs and therefore it is desirable not to manufacture more than is necessary. Fats and carbohydrates should be cut down to the minimum necessary to supply the combustion of the body. The kidneys are usually sound unless at a late stage of the disease, and therefore a free allowance of nitrogenous food is not only permissible but advisable. This food when combined with electrolytes, such as the salts of calcium, potassium and sodium, improve the electrical condition of the body, and so the health of the individual. Every cell in the body, especially the muscle cells, may be looked upon as a miniature battery, and its electrical potential depends on the difference in the potential between the ions within and without the cell. The electrolytes are essential to life and our best vitamines in health and disease.

Vaccines.—These have taken the most prominent position in prevention and treatment; an autogenous vaccine is no doubt the best if the swab be taken by the bacteriologist and immediately applied to the culture medium, but if it do not reach the bacteriologist for twenty-four hours the pathogenic organisms may be swamped by the overgrowth of the saprophytes, and all proportion lost. In such a case an ordinary stock blunderbuss might be better. Recently a distinguished physician, a man of world wide reputation told me that he had an autogenous vaccine for catarrh, but some pneumococci lodged up somewhere in the recesses of his nose had been missed, and so when the other organisms found his mucous membrane untenable, the pneumococci started business on their own account, and so he had to undergo the process all over again. I am one of those who think that the soil is of even more importance than the seed. Many of these bacteria are anions or kations which require an opposite electrical charge for their discomfiture.

Drugs.—If there be a deficiency of lime salts in the blood, which is often the case when the expectoration is abundant and albuminous, soluble lime salts should be given, especially the iodide of calcium; milk and gelatine in the diet. When the expectoration is scanty and tough, and there is much bronchial spasm, the lime is too abundant, and decalcifying agents should be used. This also applies to cases with rigid costal cartilages. The iodides and various preparations of iodine and thyroid are very useful in the spasmodic or asthmatic type of the disease. The bowels should be kept open. When there is troublesome cough, paregoric or opium and antimony are very useful. The carbonate of ammonia is not much used except as a stimulating emetic in the capillary bronchitis of children. When the acute stage has passed, tonics such as quinine, strychnine and hydrochloric acid are useful. Apomorphine and strychnine make a good tonic expectorant. In chronic cases terebene and other drugs of the turpentine series are beneficial.

Oertel (5) recommended a light dry nitrogenous diet with very little fluid and hill climbing. His patient, with a vital capacity of only 64 to 86 cubic inches, accomplished feats which would put a strong vigorous man to shame. Large corpulent, plethoric individuals do badly and should have their bulk reduced. In these cases the use of sodium chloride which has a high osmotic equivalent, should be restricted.

The treatment of emphysema should be largely dietetic and hygienic, a light, dry, nitrogenous diet a warm, dry atmosphere, iodides and decalcifying agents. As a rule there is no dyspnea except on exertion. They cannot stand high altitudes. The weight should be reduced by diet, limitation of fluid and exercise. He should be taught to expire rather than inspire, avoid tobacco and alcohol.

Hillclimbing up to 4,000 feet above sea level can be recommended, provided the vital capacity be not below 150 cubic inches in the male and 100 in the female.

For the injurious effects of high altitudes on the circulation, I can refer you to the writings of the late Alfred L. Loomis (6) and Theodore Zanger (7).

Mechanical devices have gone out of fashion except elastic bands to assist expiration. Some pa-

tients find it more comfortable to sleep in the prone position on account of the assistance afforded to expiration. No elastic band should be worn round the chest at night.

Nasal and thoracic breathing should be encouraged, in this way the costal cartilages are not so apt to become rigid, but a watch should be kept on any excess of lime salts in the blood.

Cold sponging in the mornings, the Aix douche with massage and other hydropathic measures can be commended, but the patient should not be kept long in the moist chamber. The Mont Dore cure, where there is a finely atomized spray, is at present popular in the asthmatic types of the disease. In acute attacks of asthma, speedy relief can usually be obtained by percussing between the fourth and fifth cervical vertebræ and on the second dorsal. If the heart be dilated and action labored, then the seventh cervical and second dorsal vertebræ should be concussed.

Gastrointestinal Symptoms and Epigastric Hernia

LEIGH F. WATSON, M.D.,
Chicago, Illinois.

Small epigastric hernias are sometimes accompanied by gastrointestinal symptoms which are out of all proportion in severity to the size of the hernia. In fact, sometimes a hernia is not even suspected when the patient consults his physician, and the small tumor is discovered only after a painstaking examination of the epigastric region.

The subjective symptoms include colicky pain, nausea, sour stomach, distress after eating, occasional vomiting, constipation, and a dragging sensation in the abdomen, which is due to traction on the parietal peritoneum or on the falciform ligament. Villard believed that the unusual functional symptoms may also be due to traction exerted by the round ligament on the liver.

The pain is most severe in the epigastrium and sometimes extends to the thorax, the lateral abdominal wall, lumbar region, bladder and rectum. Blumer had a patient who complained of pain radiating to the shoulders and arms, and Aaron's patient had paroxysms of pain after eating, which sometimes extended around the body and down the thighs.

Patients sometimes secure temporary relief from the pain by vomiting, or taking a small quantity of liquid food, or by lying on the back. The pain is aggravated by coughing, physical exercise, and by eating solid food. Brandenberg stated that the first symptom of hernia in the linea alba in children is usually pain in the abdomen after meals, especially after breakfast.

The objective signs are often indefinite: A small tumor, sometimes no larger than the tip of the little finger, should be looked for just above the umbilicus to the left of the median line, or it may be found, in rare instances, in the centre or just to the right of the median line. While it is unusual, the hernia occasionally appears below the umbilicus, and the suprapubic variety makes its appearance just above the symphysis pubis in the median line.

Owing to the severity of the functional symptoms, which overshadow the objective signs, the existence of a small tumor may not be thought of, and it may be discovered quite accidentally during a close examination of the abdomen. The relief of symptoms which follow the reduction of this little tumor, may give the first clue to diagnosis. The most characteristic objective sign is localized pain and tenderness on pressure over the hernia. In obese subjects a small hernia may be impalpable, but a definite point of tenderness can always be located. If the hernia is reducible it disappears when the patient is in the reclining position, and the sharp edge of the ring can be felt by making pressure on the tumor and following it with the finger through the opening, as it is reduced. Small openings in the fascia that cannot be felt when the hernia is reduced can be detected by this maneuver. Light pressure on the hernia is sometimes followed by instantaneous belching.

As early as 1748, Arnaud called attention to the importance of examining the patient in the erect position. A small hernia can often be seen in profile when the patient coughs or strains. The reflex gastric pain is probably due to traction on the great omentum, which is attached to the greater curvature of the stomach and during the attacks, a piece of the omentum is caught between the sharp edges of the slit in the fascia. When the omentum slips back into the abdominal cavity, the pain disappears. Traction on the falciform ligament of the liver is responsible for the gastric pain in those small hernias in which this ligament or the fat between its layers is the sole content of the hernia. Gussenbauer explains the severe symptoms that occur in certain cases as being due to pressure on one or more of the nerve filaments of the five lower intercostal nerves which pass through openings in the linea alba. These intercostal nerves anastomose with the phrenics in the diaphragm.

In about twenty-five per cent. of epigastric hernias with symptoms, there are changes in the gastric juice and in the physical signs of the stomach itself. The most frequent of these symptoms are: Hyperacidity, lessened motility, gastroptosis and dilatation. Alessandrini reported a case in which an epigastric

hernia and a gastric ulcer existed in the same patient; the hernia did not become painful until the ulcer developed.

DIFFERENTIAL DIAGNOSIS

Small hernias in the linea alba, especially the epigastric variety, must be distinguished from diseases of the upper abdomen.

GASTRIC AND DUODENAL ULCER

Hernia in the linea alba has often been confused with gastric or duodenal ulcer, and sometimes the two conditions exist at the same time. The presence of a tumor or a slitlike opening in the linea alba, with or without the protrusion of a small mass on coughing, will help to establish a diagnosis of hernia. In gastric ulcer there is a localized point of tenderness in the linea alba, as is always found in hernia. In ulcer the symptoms come on at a certain interval after eating, while in hernia the paroxysmal attacks have no relation to meals but usually follow physical exertion, and the patient finds that the most relief is secured by assuming a doubled up position, which relaxes the linea alba. In hernia, relief is sometimes secured by lying on the back; and in ulcer, by lying on the right side.

CHOLELITHIASIS

Hernia in the linea alba is sometimes mistaken for gallstone attacks. In hernia there will be an absence of jaundice, leucocytosis, and pain over the gallbladder, all symptoms that are characteristic of gallstone colic.

OTHER CONDITIONS

Other diseases that hernia in the linea alba has been mistaken for are: Habitual epigastric protrusion in children, gastritis, gastralgia, carcinoma of the stomach or intestine, cholecystitis, colitis, appendicitis, nephrolithiasis, angina pectoris, abscess or tumor in the abdominal wall, and the gastric crises of tabes.

RÖNTGEN RAY EXAMINATION

When the epigastric hernia is complicated by gastrointestinal symptoms, even though they are mild, a röntgen ray examination is important for diagnosis because of the frequent association of gastric and duodenal ulcer with this variety of hernia. Sometimes when the röntgen ray examination is negative it is advisable to do an exploratory laparotomy at the time of the hernioplasty.

30 North Michigan Avenue.

Renal Infection

S. WILLIAM SCHAPIRA, M.D.,
New York,
and JOSEPH WITTENBERG, M.D.,
Brooklyn.

Renal infection is an inflammation of the kidney or its pelvis due to pyogenic organisms. Tuberculosis of the kidney is not considered with this group because the tubercle bacillus is pathogenic rather than pyogenic.

The normal kidney is resistant to infection; it eliminates disease producing germs without apparent damage. Infection occurs only after the resistance of the kidney has been lowered by some general or local cause. The general cause may be any acute infection or chronic exhausting disease; and anything which will produce local congestion of the organ will act as the local predisposing cause. Examples of the latter are, 1, mechanical irritation by a calculus; 2, congestion about a tumor or an ulceration; 3, congestion due to retention of urine above some obstruction; and 4, irritation of the organ by urine which contains an excess of chemical or bacterial irritants.

The exciting germs most often found in infection of the kidney are the colon bacilli; these account for about seventy-five per cent. of all the cases. This shows how necessary it is for the physician always to bear in mind that colon bacilli penetrate the healthy mucous membrane of the intestines after two days of constipation; and when the mucous membrane is diseased the passage of these germs into the blood is still easier. The other germs most commonly found in renal infection are the staphylococcus, streptococcus, the Bacillus proteus vulgaris, Bacillus pyocyaneus, and less often the pneumococcus, gonococcus and an anerobic germ.

Routes of infection.—The most common routes taken by the infecting organisms are supposed to be the hematogenous and urogenous; other paths are the lymphatic and direct extension from neighboring infected areas; infection may be implanted at the time a kidney is wounded.

It is probable that cases of renal infection that follow inflammation of the lower urinary tract are generally extensions of the original infection through the lymphatics in the coats of the ureters which connect the lymphatics about the bladder and those of the kidneys, or they are hematogenous infections, the microorganisms entering the circulation from these lymphatics and landing in the kidneys.

Kinds of renal infection.—We will divide renal infections, first, into nonsurgical and surgical. By the term nonsurgical we mean an infection where local treatment or surgical intervention in any form is clearly useless to improve the condition of the kidney or to attempt to save life. We will dismiss the nonsurgical form with these few words: Occasionally the irritation produced by the infecting organisms though persistent is too mild to produce noticeable amounts of pus. A proliferative inflammation sets in which finally produces a chronic interstitial nephritis with the usual symptoms of this condition plus a bacteriuria.

The surgical form of renal infection is the on

usually found. Suppuration is present, or where an infectious pyelitis is catarrhal it may progress to suppuration.

It is not necessary nor advisable in a paper such as this to dwell long on the divisions and subdivisions of the pathological changes of renal infection; they are all different degrees of the same process. The divisions usually made are: Bacteriuria (of renal origin) where the pus is microscopic in amount but the bacteria are present in enormous numbers; pyelitis—acute catarrhal, chronic catarrhal, and suppurative; nephritis—the nonsuppurative, infectious catarrhal form—the nonsurgical form mentioned above; suppurative forms: a, focal or miliary suppurative foci, b, abscess; this is usually due to the coalation of several miliary foci; suppurative pyelonephritis, acute and chronic; and pyonephrosis which is really an exaggerated pyelonephritis.

SYMPTOMS OF RENAL INFECTION

The most important symptoms of renal infection can be placed in the following groups: 1 Changes in the urine; 2, the symptoms of sepsis, due to the infection; 3, symptoms of renal insufficiency following extensive destruction or damage of kidney tissue; 4, local symptoms due to the local pathological changes, and 5, certain reflex symptoms that are found with renal infections.

1. Changes in the urine:

a. Bacteriuria: This is present in greater or lesser degree in every case of renal infection. The germs may be present in such numbers as to make the urine hazy and give it a foul odor.

b. Pyuria is present provided any pus which has formed has freedom of exit; viz., if the pus can flow into the renal pelvis and out with the urine. If pus which has formed can not escape, the urine is clear but symptoms of sepsis, chill, fever, sweat, etc., may be present due to absorption of the pus; and locally, pain and tenderness may be present at the region of the kidney from tension by the retained pus, and tumor from the mass of pus in the kidney.

c. The quality of the urine—the amount of urea and other solids it contains depends on the amount of destruction and other damage of renal tissue.

2. Symptoms of sepsis: These vary from mild nausea and malaise to vomiting, chill, fever and sweat depending on the severity of the sepsis. Severe symptoms are present also when the onset of the disease is sudden.

3. Renal insufficiency must follow extensive damage to the kidneys. Uremic symptoms set in, the patient complains of headache and vertigo, the skin and tongue are dry, there is a urinous odor about the patient, diarrhea may be present and finally delirium, convulsions and coma appear. Calculus anuria, which is due to a reflex inhibition of kidney function, gives a peculiar type of uremia that has been described in the section on renal calculi.

4. Local symptoms: Pain or discomfort may occur with any increase of tension within the kidney capsule or as a result of increased weight of the enlarged organ; the increased tension may also cause local tenderness. With sudden obstruction of the ureter, which may occur especially when the infection is accompanied by a calculus, the pain may be severe—as severe as a renal colic. Enlargement of the kidney is often felt, but not in every case of renal infection is the organ enlarged; when the pathological change is in the form of an interstitial nephritis, the kidney is smaller than normal.

5. Under reflex symptoms we find symptoms of irritation that are referred from the kidney or ureter to the bladder—frequent, painful urination and even tenesmus without any visible lesion in the bladder—just as in other cases pain is referred to the kidney from lesions below, i. e., lesions in the bladder and lower part of the ureter. If cystitis is present with the pyelonephritis, the latter may be overlooked.

Another noteworthy group of symptoms often foci, b, abscess; this is usually due to the coalition of the gastrointestinal tract which simulate toxic symptoms but are entirely out of proportion to the possible absorption of pus from the infected kidney.

COURSE OF RENAL INFECTIONS

Bacteriuria: The course of this mild form of infection varies. The disease may disappear promptly, it may last for years, or its symptoms may come and go. The general health remains good but there is always danger of more severe involvement of the kidney, should its resistance be lowered. Diagnosis of bacteriuria is made by the haziness of the urine and by microscopical examination of its sediment. This haziness is not affected at all by heat nor chemicals and but little by the centrifuge unless the urine is first diluted with an equal volume of absolute alcohol.

If the colon bacillus is the causative germ, the urine is acid and the lesion is usually in the renal pelvis; if the streptococcus or staphylococcus is the germ at fault, the urine is alkaline and the lesion is generally in the prostate. Drawing the urine from the individual kidneys will readily show if the lesion is in either kidney or in neither; clear urine from both kidneys and a contaminated urine from the bladder show that the lesion is below the kidneys and ureters—usually in the prostate.

With severer form of renal infection—catarrhal pyelitis or suppuration anywhere in the kidney or its pelvis—symptoms are more severe and varied. It is best to divide the course of the disease into acute and chronic. Where the onset is sudden or where considerable pus is retained the symptoms are severe; we find chills, fever and sweat, nausea and vomiting, prostration, mental dullness, and other symptoms. Local pain follows sudden tension within the kidney capsule and with it tenderness appears at a renal pain area. The fever may be continuous, remittent or intermittent. With the discharge of pus which had been retained, the severe symptoms subside but the urine which had been clear becomes purulent. If the kidney structure is involved extensively, uremic symptoms set in and death may ensue.

In fulminant cases death may occur before any pus is formed; the kidneys are found filled with the invading microorganisms. In nonfulminant cases the symptoms subside after two or three weeks, the fever falling by crisis or lysis; but the attacks are apt to recur for some months on getting out of bed. In still other cases the symptoms persist for from three to six weeks with periods of remission but no intermissions and death occurs from uremia.

In chronic forms of renal infection whether these

follow the acute form or are chronic *ab initio,* the symptoms are much milder and may not be noticed for some time. In most cases symptoms of several of the groups mentioned above are found together; and acute and subacute attacks are not uncommon.

The course of renal infection depends largely on the drainage of the suppurating areas. With good drainage it is possible for destroyed tissue to be discharged and the lesion to scarify after weeks or months or years. This may not be so rare in tuberculosis of the kidney as is generally supposed. The effects of sclerosis are mitigated or annulled by compensatory hypertrophy of neighboring parenchymatous tissue.

When death occurs it is due to uremia or some intercurrent affection.

PYELITIS IN CHILDREN

Pyelitis of infancy and childhood, a condition not at all uncommon, occurs principally in females and at from several months to several years of age. A history of enteritis is obtained usually; the child is perhaps constipated most of the time and has had attacks of diarrhea. At times it has painful, bloody stools and its anus is sore.

The onset may be severe with chills and fever of 104 or 106, and vomiting, delirium and squint may be present. The fever is peculiarly irregular, shooting up and down and perhaps not alike any two days. Tenderness of the kidney is a very important symptom when present; it may, however, be missing. The urine is acid and shows traces of albumin, pus, germs, cells of pelvic and bladder epithelium and hyaline and granular casts.

In an infant, chills without malaria are suggestive and high fever and distress without sufficient apparent cause are suspicious of pyelitis. Diagnosis is made by the discovery of pus and germs in the urine. The symptoms subside in a week or ten days under treatment and in most untreated cases the patients recover spontaneously; very few die. Pus and especially bacteria may persist in the urine for weeks or longer, and it is essential to treat the patient till the germs disappear.

DIAGNOSIS

In making a diagnosis, include, if possible, a, the location of the original focus of infection; b, the freedom (or lack of freedom) of drainage for any pus or products of inflammation that may be present; c, the presence or absence of calculi, etc., as a complication; d, the amount of destruction of the affected kidney—its functional capacity; e, the functional capacity of the second kidney, and f, the infecting organism.

The focus of infection may be in a tonsil, the adenoids, the nose or its accessory sinuses, the roots of the teeth, the prostate, a seminal vesicle, the uterus or ovaries; the importance of the intestinal canal as a source of infection has already been mentioned. Pus which has a more or less free exit through the urine, gives pyuria. Retained pus is apt to cause fever and the other symptoms of sepsis mentioned above, while the urine is free from renal pus. The functional capacity of the diseased kidney and of the second kidney is ascertained by some of the renal function tests. The presence or absence of complicating renal calculi, etc., is demonstrated by the history, the x ray, pyelography, etc.

PROGNOSIS

The prognosis depends upon the freedom of drainage of the infected area or on the possibility of establishing free drainage, on the amount of kidney tissue destroyed, on the presence of complicating calculi and the possibility of their removal.

Renal bacteriuria may disappear readily, it may persist for years or come and go. The general health may be good but danger of further infection of the kidney is always present, should the resistance of that organ be temporarily weakened from any cause.

Acute catarrhal pyelitis is cured readily, even spontaneously, if no permanent predisposing cause is present, such as obstruction in the urinary tract, calculus, and other conditions. If the condition does not disappear it may go on to suppurative pyelonephritis or focal suppurative nephritis.

The outlook for recovery from catarrhal pyelonephritis or pyelitis is fair if drainage is free and proper treatment is given.

The prognosis of acute suppurative conditions of the kidney varies with the pathological changes present. In fulminating forms, the patient dies in several days; in forms which are less severe and in which the drainage is free or is made so, the condition becomes chronic and we get a compensatory hypertrophy of healthy renal tissue to take the place of that destroyed. Multiple (focal) abscesses can not be drained well and necessitate nephrectomy.

Chronic suppurative pyelonephritis may improve markedly, even after years, if the drainage is good. Diseased tissue may be discharged, the lesions scarify and neighboring renal tissue undergo compensatory hypertrophy. If a mild inflammation persists, a chronic interstitial nephritis develops.

Pyonephrosis, a condition in which the kidney is practically destroyed, may terminate in one of several ways. The patient may die of sepsis or anuria; a closed abscess may burst into the ureter and be discharged, or it may open into the perinephric sac or into some neighboring organ; the pyonephrosis may be destroyed by the pus becoming caseated or the organ undergoing fibrofatty degeneration.

TREATMENT

The treatment of renal infections may be divided into operative and nonoperative. Operative treatment is ordinarily necessary in two classes of cases: 1, where there is any interference with the free drainage from the kidney, whether the obstruction be in the urethra, at the prostate, in the bladder, at the ureter from kinks or from pressure upon it, or at the renal pelvis from calculi or tumor. Relief of such obstruction removes the great obstacle to cure and at the same time removes the predisposing cause for the infection of the kidney; 2, when purulent conditions exist which can not be cured by the defensive action of the body and the removal of which offers hope of cure of the patient. In such cases save all kidney tissue possible.

Nonoperative treatment of renal infection includes 1, expectant treatment: This is used in cases where no indication exists for surgical intervention and which are expected to recover especially if the symptoms are alleviated and Nature is assisted. 2. Curative treatment: This consists of the administration of sera and vaccines. Sera are given to neutralize the toxins produced by the infecting organisms and are

therefore indicated in the acute stage of the infection; vaccines stimulate the reaction of the body to the germs from which they are made and are of most service in chronic conditions. 3. Palliative treatment is used to relieve symptoms in cases that can not be cured by any method of treatment.

Among the measures used in expectant and palliative treatment of renal infections, flushing of the kidneys by drinking plenty of water and administering urinary antiseptics are of importance. Direct treatment of the renal pelves—lavage and instillation through the ureteral catheter is often of much benefit, according to our observations.

RENAL TUBERCULOSIS.

As is the case with renal infection by pyogenic germs, tuberculosis attacks the kidney only after this organ has been weakened by some general or local process; for the tubercle bacillus, like pyogenic germs, passes through the normal kidney with no apparent damage.

Theoretically there is no reason why the kidney may not be the first organ in the body to be infected with tuberculosis; for it is conceivable that tubercle bacilli which enter the body by any route, may be passed on to a kidney which has become susceptible. However, experience shows that practically every case of tuberculosis of the kidney has been preceded by a tuberculous infection of some other organ.

Renal tuberculosis is found most commonly, though by no means always, in patients between twenty and forty years of age, except where it is part of an acute miliary tuberculosis which usually comes in children.

The routes by which the tubercle bacilli reach the kidney are those along which pyogenic infections spread, viz., through the blood stream, under certain conditions through the urinary passages, along the lymphatics and by contiguity; the hematogenous route is the usual one.

Bilateral involvement is of more importance here than in pyogenic infection; for, once the kidney is tuberculous, none have ever been found, at autopsy, to be completely cured. Another and important reason is that after one kidney is infected with tuberculosis there seems to be a strong tendency for the second kidney to become similarly involved. It is therefore of the utmost importance to make a correct diagnosis early, whether renal tuberculosis is present, if one or both kidneys are involved, to ascertain the presence or absence of complications—pyogenic infection or calculus, and the functional capacity of each kidney.

Statistics show that when the patients are first seen, both kidneys are involved in ten per cent. of the cases, by the time operation is performed, in twenty-five to thirty per cent. and in those who die of renal tuberculosis or of shock following operation for this condition, in sixty to sixty-five per cent. Suppuration of the kidney is due to a complicating infection with pyogenic organisms.

Types of renal tuberculosis.—We can divide tuberculosis of the kidneys into nonsurgical and surgical if we understand by surgical kidney one that may be benefited by operation or the removal of which may conceivably be of benefit to the patient. For example, the kidney that is involved in an attack of acute miliary tuberculosis can not be considered fit for surgical intervention. Again, a toxic tuberculous nephritis is found as a result of elimination of toxins produced in some tuberculous focus outside that kidney; operation on this kidney is not indicated because the organ is not a source of infection and we may expect the nephritis to improve if the source of irritation is removed. Still another though rare nonsurgical form of tuberculous kidney is a fibrous tuberculous nephritis with giant cells but no caseation.

We divide surgical tuberculous kidneys according to the location of the lesions into the parenchymatous, pelvic and papillary types.

In the papillary form the first lesion is on a renal papilla. The tubercle ulcerates rapidly and as the tip of the papilla is very vascular, profuse hematuria may result. This type is rare.

The pelvic form of renal tuberculosis where the first lesions are in the pelvic wall is also unusual. This part of the kidney is involved more commonly by extension to it of the tuberculous process from the parenchyma. The walls thicken and ulcerate, and sclerosis with contraction of the tissues of the pelvic wall or of the tissues about it which also become sclerotic because of the local irritation, may shut off the kidney or a part of it—one or more calyces, and form a complete or partial hydronephrosis.

The usual form of renal tuberculosis is the parenchymatous type. The lesions are first formed at either pole; the miliary tubercles coalesce and caseate. Ulceration results from secondary infection. In time the tuberculous masses break down and discharge into the renal pelvis; and the liberated tubercle bacilli infect the pelvic walls. Occasionally the tubercles ulcerate through the kidney capsule into the perirenal fat and give rise to a tuberculous perirenal abscess. Still other lesions undergo caseation and calcification.

The amount of damage that may be found varies from a small tubercle to total destruction of the kidney. This depends on the virulence of the process, on the amount of obstruction to the flow of urine, also on the rapidity of the formation of this obstruction, and on the presence or absence of mixed infection.

The rapidity with which the disease spreads varies much. Destruction may be very rapid, or it may be very gradual and the patient live for years. In most cases the first symptoms appear long after pathological changes have set in; and then they may be so mild as to be ignored for some time.

The symptoms which may be found with renal tuberculosis are, a, general symptoms of tuberculosis—fever, loss of weight, etc.; b, local symptoms of the pathological changes, viz., pain, local and reflected; c, urinary disturbances—frequent, painful urination, hematuria and pyuria.

Aside from observing the presence of these symptoms we have recourse, in making the diagnosis, to cystoscopic examination for changes in the bladder mucosa and to ureteral catheterization to secure urine from the individual kidneys for examination and comparison. We also have recourse to laboratory methods in searching for the causative organism.

General symptoms.—The evening rise of temperature, a common symptom in tuberculosis, is present in a fifth or a quarter of the cases of renal tubercu-

losis; when the bladder becomes involved, the percentage rises to 80. Chills, fever and sweat point to secondary pyogenic infection. Signs of tuberculosis may be found in other organs.

Local symptoms.—Pain is present most commonly as a dull ache; this becomes intensified with the onset of acute congestion due to any cause. Pain that is still more severe follows sudden blocking of the ureter with the increased tension by the accumulating urine and the acute congestion accompanying it. A comparatively healthy kidney which has added work thrown upon it suddenly, with resulting acute congestion, may pain more severely than its more extensively diseased fellow. Tenderness of the kidney is often elicited by bimanual examination.

Tumor develops very slowly when the enlargement consists of caseated masses. Complications like perinephritis or a slowly formed pyonephrosis produce large masses.

Reflex pains.—With a diseased seminal vesicle we sometimes find pain in the loin; and, in the presence of a tuberculous kidney on the other side an incorrect diagnosis of tuberculosis of the second kidney may be made. A painful condition of a kidney may give socalled crossed pains—the pain is felt in the region of the healthy kidney and none at the diseased kidney. This is the socalled renorenal reflex. Bladder pain, felt in the suprapubic region or perineum, is often present with renal tuberculosis; it may be the most marked symptom even though the bladder shows no sign of any pathological change.

Urinary symptoms.—Polyuria, increased frequency, dysuria, hematuria and pyuria are found in many other kidney conditions as well as in renal tuberculosis. We attempt to differentiate these conditions by certain variations in these symptoms.

Polyuria is found with any irritation of the kidney or its pelvis except in the stage of acute congestion when oliguria is present.

Frequent urination is due in part to the polyuria, also in some cases to irritation by lesions in the bladder and in others to the reflex irritation of the bladder which is so often found with tuberculosis of any part of the urogenital tract. The great frequency of the latter was shown by the writers in an extended study of the urogenital tract in tuberculosis (The Urinary Tract in Pulmonary Tuberculosis, *Journal A. M. A.*, March 2, 1918). In tuberculosis of the urogenital tract the diurnal and nocturnal urination are equally frequent, differing largely from the frequency of urination found with other conditions.

Dysuria is due in the early stages to the irritation by toxic urine and perhaps to the reflex irritation of the bladder mentioned above; and later to ulceration of the trigone, when the frequency, pain and tenesmus may be extreme.

Hematuria, a common symptom in renal tuberculosis, generally appears first after the separation of a caseous mass. Later attacks come at infrequent, irregular intervals, without regard to activity or rest of the patient. The hemorrhage is scanty as compared to that from renal tumor, and painless as compared to that of renal calculus. A few red cells are always present.

Pyuria.—A few pus cells can always be found but considerable amounts appear only after a complicating pyogenic infection sets in.

Cystoscopic findings.—The bladder may appear normal when the kidney is already affected to a considerable extent; on the other hand tubercles or ulcerations at or near the ureteral mouth are strongly indicative of tuberculosis of the kidney above. Similar lesions about the mouth of the bladder point to tuberculosis of the prostate. Involvement of the ureter is accompanied by swelling or ulceration of its mouth and if the pathological changes are extensive the tube becomes shortened and may pull on the trigone sufficiently to convert the prominence about the ureteral opening into a funnel shaped depression.

Laboratory findings.—When the kidney is damaged sufficiently, its eliminating and concentrating power are lessened; the amount of urine is increased, but the specific gravity is lowered and the elimination of solids is diminished. The urine contains pus cells, red cells and casts.

The tubercle bacilli may be difficult to find with the microscope, especially as they may be eliminated only at intervals, in showers, in some cases. Animal inoculation will usually disclose their presence when the microscope does not. It is well to call attention here to the fact that tubercle bacilli may be eliminated by a normal kidney; this fact makes a diagnosis of tuberculosis of a kidney on the strength of this sign alone—without sufficient corroborative evidence unjustifiable. This caution is especially necessary at present when there seems to be a tendency to remove all kidneys in any way affected with tuberculosis, if the second kidney is supposed to be unaffected; or to remove the worse kidney when the second kidney, though involved, is still capable of supporting life.

Diagnosis of renal tuberculosis.—Judging from the statements above, it is evidently as difficult as it is important to make an early diagnosis of renal tuberculosis. Frequent, painful urination, both diurnal and nocturnal, are suspicious of tuberculosis somewhere in the urogenital tract. Hematuria which is usually slight and appears at irregular intervals coming and going without apparent cause and with the blood and urine well mixed, is suggestive of renal tuberculosis. Cystoscopic examination may show tuberculous lesions at or near the ureteral orifice. Tubercle bacilli found in the urine drawn from either kidney is presumptive evidence of tuberculosis of that organ but is not conclusive; if with the bacilli we find evidences of tissue destruction, pus and other conditions, the diagnosis is positive.

Prognosis.—The rapidity of the spread of the process depends on the patient's power of resistance and on the presence or absence of secondary infection. The bladder as a rule becomes involved within two years after infection of the kidney. The second kidney becomes involved in a considerable number of cases as was mentioned above.

As we have already stated, a kidney once tuberculous has never been found at autopsy to be entirely healed; and tuberculosis of the kidney is more quickly fatal than tuberculosis of any other urogenital organ. The longevity varies from a few months to ten or more years after the appearance of symptoms. We know of cases of longer duration than ten years where the patients are apparently doing well without operative interference.

TREATMENT OF RENAL TUBERCULOSIS

General antituberculosis treatment is always given and may be of great value, especially when combined with a change to a suitable climate. Symptomatic treatment directed to the bladder to relieve the frequent, painful urination is necessary to keep the patient as comfortable as possible.

The question of surgical treatment of renal tuberculosis is of great importance and is not easily answered in every case. The urge to nephrectomy lies in the fact that the prognosis of nonoperated cases is not very good; but the question must always arise, "Is it not likely, or possible, that operation on this particular case will do more harm than good?" We will attempt to summarize the reasons for and against operative treatment here:

Reasons against operation: 1. Few kidneys are so badly damaged but that they have some function; unless indeed the kidney is a closed pus sac. 2. After one sees, as we have seen, a number of patients with pronounced tuberculosis of the second kidney soon after the first kidney had been removed for tuberculosis, he feels less certain of the ease of diagnosing renal tuberculosis that is limited or almost limited to one kidney, and hesitates to do a nephrectomy in such a case unless the indications for it are clear. 3. After removal of one kidney, the other being healthy, the second kidney may become infected from some other tuberculous organ, as was the first.

On the other hand, as reason for nephrectomy, we will place:

1. A kidney that is badly diseased may produce sufficient toxins to irritate the second kidney, during their elimination, and this may be sufficient to more than counterbalance the value of whatever specific function the tuberculous kidney has left. Such a kidney should be removed at once, if the second one is in good enough condition to maintain life.

Obstetrical Paralysis

ETHAN H. SMITH, M.D.,
San Francisco

Glancing over the literature of this subject, one notes that there has been a great divergence of opinion as to its cause. Originally the cause was ascribed to pressure. The literature does not clearly state as to when this pressure occurred, but the word is used in such a manner as to convey the impression that the pressure had extended over an indefinite prenatal period. Opposed to this theory are the opinions of a number of celebrated men, among them the late Sir Victor Horsley, who was known to be so thorough and painstaking in his investigations that one might well hesitate to dispute his findings which were based partially on dissection.

Much speculation has been indulged in with regard to the possible effect of the pressure of bones on nerve branches, and also the stretching of nerves to the possibility of rupture, during the passage of the infant through the birth canal. It is maintained that it does not matter whether the child presents by the head or by the breech; the condition may occur seemingly with equal facility in either presentation. It is stated as a matter of observation that only one case occurs in about two thousand births. If we are to accept this as a basis of study, it may well be asked why obstetrical paralysis is not fairly common instead of being relatively infrequent. With the greater number of instrumental deliveries, seemingly ever increasing during the three last decades, it certainly raises a great deal of doubt as to pressure and stretching of the nerves being responsible for this condition.

With so many individuals of varying degrees of skill in obstetrical practice, many of them not hesitating to apply forceps, it would seem that there should have been a great increase in the number of cases, if the condition was due to stretching and manipulation of the child's head, neck and upper extremities, during the instrumental delivery. More than that, there should be a great predominance of cases occurring in head presentation over those occurring by breech presentation. According to statistics, this does not seem to be the case.

To any one giving careful study to the matter of pressure on nerve trunks by the bony structures, it will be found that it is a difficult matter for any bone or combination of bones to impinge upon a nerve trunk so as to produce even a temporary damage to the nerve, so long as the bones and joints are neither fractured nor dislocated.

Much has been written and spoken concerning nerve injury in many different departments of surgery, from this source. The most of such assertions have been thoughtlessly made and purely from a speculative viewpoint. Nerve trunks may be overstretched when a part is pulled into extreme overextension, but this does not happen often. The fact that in obstetrical paralysis most of the disability is due to a spastic condition of the muscles involved, and that only a few of the muscles are involved, is worthy of serious study.

If there was a tearing of the nerve trunks, it would seem that, considering the nerves involved, there should be a more complete paralysis both sensory and motor, than is seen in these cases. It would seem as though there should be well nigh complete paralysis of a whole extremity instead of a limited paralysis, as is found in most cases. This muscular derangement will be found in many cases to involve the following muscles:

Muscles involved in the posterior scapular region —the infraspinatus possibly, but the teres minor and teres major positively. The latissimus dorsi never seems to be involved, nor can it be demonstrated that the triceps is involved. Anteriorly, the pectoralis major and minor are involved. The infraspinatus muscle is supplied by the fifth and sixth cervical nerves, through the suprascapular nerve; the teres minor by the fifth cervical, through the circumflex,

and the teres major by the fifth and sixth cervical, through the lower subscapular. The pectoralis major and minor muscles are involved. These muscles are supplied by the external and internal anterior thoracic nerves. The pectoralis major receives filaments from all the branches entering into the brachial plexus. The pronator radii teres is also involved. It is supplied from fibres from the sixth and seventh cervical. These muscles will be found markedly spastic. By gentle manipulation for a few minutes, the spasticity may be so overcome as to permit raising of the arm, forearm and hand at a nearly vertical position above the shoulder. This cannot be accomplished in a child in whom the deformity has persisted for some months or years. The deltoid muscle will be found flaccid and almost incapable of function. The supraspinatus, because of its peculiar location, cannot be so well estimated, but is apparently partially functionless.

To be sure, the opinion stated above is formed from a study of the usual type of cases, and not as an observation of any one particular, extensive case. It may occur in cases where there has been no instrumental delivery. In two cases coming within my own practice, the mother stated that the birth was seemingly normal and of no more than ordinary duration or severity. In one instance, the mother's statement was verified by the attending physician.

PROGNOSIS

As to prognosis, my opinion must be based on comparatively few cases, and is not given with a view to refute or dispute the opinions of many previous observers. If appropriate treatment is established within a few days after the infant is born, many of these patients will make a recovery so perfect that it is difficult tto find any deviation from the normal. If treatment is delayed for a few months, the results will still be good, but not perfect. If treatment is delayed for several years, much good may be accomplished in some cases; some good in quite a number more; and little or no results in perhaps one third of the neglected cases.

TREATMENT

A brace with a corsetlike part for the body, sufficiently reinforced by steel to make it secure, is placed on the child's body, extending from above the nipple to the waist line. This must be so constructed as not to cause pressure on bony prominences on the infant's body. Attached to this, on the side involved, should be a splint for supporting the arm and forearm to the hand, and so fashioned that the extremity may be gradually raised laterally from the body with the elbow of the splint hinged so as to flex or extend the forearm during part of the time.

The splint should be so hinged at the shoulder that the extremity may be raised both upward and backward until finally the extremity may be brought nearly to the perpendicular in extension, and carried backward posteriorly beyond the midlateral line of the body to a degree easily possible for the normal extremity.

If this appliance is put on within the first few days after the birth of an infant suffering from obstetrical paralysis, and kept on with the arm raised to nearly a right angle to the trunk and the forearm semiflexed, during the twenty-four hours, and extension increased during a portion of the day time, we may hope for a satisfactory result within from four to six months.

Owing to the difficulty of holding the forearm and hand in marked supination, the spastic condition of the pronator radii teres will be hardest to overcome.

The opinions herein expressed are based on a successful handling of about a dozen cases. I submit them for what they are worth. I realize that it is merely a start; but I believe that the results thus far obtained will fully warrant careful trial and investigation on the part of the profession.

Electricity and massage are, I believe, a waste of time in the beginning. Electricity is not indicated at all. Massage, as a follow-up measure, after the necessity for the brace has passed, I believe would be beneficial.

528 Flood Building.

Results of Lautenschlager-Halle Method of Ozena Operation*

J. COLEMAN SCAL, M.D.,
New York

Much interest has been aroused by the Lautenschlager-Halle operation for the cure or amelioration of symptoms of ozena. I am publishing these findings almost prematurely lest undue enthusiasm cause injury to those it is intended to benefit.

The treatment of ozena today is satisfactory to neither the patient nor the physician. There are many methods for narrowing the nasal cavities and thus eliminating one factor which favors accumulation of fetid crusts; but the one devised by Lautenschlager and modified by Halle appears to serve the purpose best. While we feel that this operation will make the lumen of the nares narrower, we are not satisfied that it will entirely cure the ozena.

To perform the Lautenschlager-Halle operation paint the entire nasal mucous membrane with twenty per cent. cocaine to which a few drops of adrenalin have been added. Then inject one half per cent. solution of novocaine and adrenalin into the mucosa of the septum; into the floor of nose; and into the lateral nasal wall, especially in front of the turbinates and lower nasal duct.

The incision is started immediately in front of the middle turbinate and continued down past the front of the inferior turbinate to the floor of the nose, and across the floor to the septum. The incision extends down to the bone. The mucosa, the periosteum of the entire floor of the nose, and the lateral nasal wall in front of both turbinates are then elevated.

*Read before alumni association of Beth Israel Hospital, May 3, 1923.

The lower borderline to the floor of the nose of the lateral nasal wall is then chiseled submucously as far back as the posterior wall of the antrum. The antrum is entered and the separated lateral nasal wall is displaced as far as the septum, after first freshening with a curette the median surface of the inferior turbinate and the corresponding portion of the septum. The antrum of Highmore is packed tightly with gauze tape so that the displaced lateral nasal wall is kept in its new position.

The packing is changed after five days and renewed at intervals of two days until the antrum is completely closed. This packing is continued as long as possible in order to support the nasal wall in its new position. The operation, not counting the time until the anesthesia becomes effective, should not take more than thirty to forty-five minutes.

While most of the operations were performed without difficulty, one, owing to thick bone and small antrum, caused considerable technical difficulty.

The treatment can be ambulatory in all cases, although we admitted our first two patients to the hospital for the first twenty-four hours. Pronounced reactions were not observed, the patients were prevented from going about their work for only three to five days.

CASE REPORTS

CASE I.—J. R., aged thirty-eight, housewife. For ten years neighbors had called her attention to the odor from her nose. The patient complained of continuous mucous secretion in the throat and scabs in the nose. Had undergone treatment without improvement. Rhinological examination showed the septum deviated to the right, with both middle and inferior turbinate bones atrophied. Both nares were covered with closely adherent crusts and putrid secretion. After removal of these crusts with a bulb syringe, the mucous membrane appeared pale and of a grayish color. The nasopharynx was easily visible and its roof was covered with crusts. The pharyngeal wall was dry.

An x ray revealed both antra cloudy but exploratory irrigation yielded only clear fluid. The Wassermann was negative. Operation was done according to the Lautenschlager-Halle method at the right nostril September 22, 1922, at the left nostril October 8, 1922.

FINDINGS EIGHT WEEKS AFTER OPERATION

The nose was considerably narrowed. At the right, synechia was holding the lower turbinate to the septum. The opening into the antrum was closed. The approximation of the lateral nasal wall which existed after the operation was diminished. At the left a similar condition existed with a slight formation of crusts and the fetor was still present.

FINDINGS THREE MONTHS AFTER OPERATION

Patient admitted slight improvement. She could breathe better, but slight amount of crusts and fetor were still present. Approximation of the lateral nasal wall and the septum were diminished.

FINDINGS SIX MONTHS AFTER OPERATION

The right nostril was not yet clear of crusts and fetor. In the left nostril a small amount of crusts were still present. The lateral nasal walls had kept their previous position. Patient now stated improvement was hardly noticeable.

CASE II.—E. S., aged twenty-eight, married, housewife. For several years she complained of fetor, formation of crusts, and dryness in the pharynx. She also was prone to frequent attacks of hoarseness.

General examination showed patient to be normal. Wassermann was negative. Rhinological examination showed a typical advanced case of ozena with marked fetor; the septum was deviated to the right, the turbinates were atrophic, and both nostrils were dilated. The turbinates, the septum, and the floor of the nose were covered with scabs. The patient had lost sense of smell. She had been treated for two years without improvement. X ray showed clouding of both antra. The other accessory sinuses were clear. Exploratory puncture showed maxillary sinuses were negative.

The left nostril was operated on October 2, 1922, and the right October 18, 1922. Very thick bone caused considerable technical difficulty in this operation. The antrum was very small so that the displacement and approximation of the lateral nasal wall created the impression that the operation was not a complete success. Only a small packing which did not seem to support the approximation completely could be inserted.

FINDINGS SIX WEEKS AFTER OPERATION

Patient stated she had somewhat regained the sense of smell. Examination showed the lower turbinates approximated to the septum and held there by synechia. The mucous membrane appeared healthier and redder with small amount of crusts but no fetor present.

FINDINGS FIVE MONTHS AFTER OPERATION

Patient did not admit of any improvement. Examination showed the lateral nasal walls still approximated to septum. Crusts and fetor were still present.

CASE III.—F. W., aged twenty-nine, married, housewife. Complained of fetor and formation of crusts for past six to eight years; dryness of throat; and occasional hoarseness lasting one week to ten days. Examination revealed an atrophic nose. The septum and posterior part of the nares were covered with grayish black scabs. The x ray showed that both antra were cloudy but no pus was found present on exploratory puncture. The Wassermann reaction was negative.

The left nares was operated upon September 29, 1922, and the right October 23, 1922.

FINDINGS TEN WEEKS AFTER OPERATION

Both nares were considerably narrower, with septum and turbinates covered with small scabs and considerable amount of pus present on floor of each nostril.

FINDINGS FIVE MONTHS AFTER OPERATION

Nose still narrow, small amount of pus and crusts still present, fetor was gone. The patient did not admit improvement, and still has to use a nasal syphon to keep her nose clear of pus and scabs.

CONCLUSIONS

To draw conclusions from so small a number of cases[1] in so short a time is wrong. We must concede, however, that in a few of the cases there seemed

[1]Due to lack of space three of the author's cases were omitted.

to be some improvement in the ozenic symptoms at the beginning. Although the crusts and the characteristic fetor were still noted, the mucous membrane was redder and healthier in appearance, and the patients admitted some improvement.

It will be many years before we can determine whether this operative narrowing of the nose will be lasting or whether it will assume a place among the many unsuccessful methods of cure for ozena.

After the uniformly bad results in these six cases I have determined to discontinue this treatment as I find the patients derive no benefit from being submitted to all the annoyance of the operation.

950 Park Avenue.

Headaches of Nasal Origin*

LOUIS BAER, M.D.,
Philadelphia, Pa.

Headache is a symptom often complained of in many diseases. While a few headaches are definite and clear cut in character, permitting a diagnosis as to the source of the trouble, the majority are complicated, the pathology being obscure and diagnosis perplexing to the clinician. It often requires the closest observation, and the aid of many specialists, such as the ophthalmologist, the rhinologist, the gynecologist, and the laboratory, to elucidate the underlying cause. And there are headaches which are not cleared up after the most exhaustive study. To mask our ignorance, we call them neuralgia.

Of recent years practitioners of medicine have come to recognize that disease of the nasal chambers and accessory sinuses is in many cases responsible for obscure headaches and neuralgias. In fact, certain authorities assert that the greatest percentage of obscure headaches not diagnosed are of nasal origin.

In this paper I shall attempt to point out the anatomical disturbances of the nose and adjacent sinuses causing pressure and subsequently localized inflammation of certain cranial nerve areas. In order to have a clear understanding of the subject under discussion, a brief review of the anatomy and physiology of the nose will be of great help.

ANATOMY AND PHYSIOLOGY OF THE NOSE

The nose is divided by the nasal septum into two chambers, the right and left. Each chamber is again divided by the inferior and middle turbinate, into the inferior, middle, and superior meatus. The nasal chambers are lined with ciliated epithelium except the attic or uppermost part of the chamber, where it is lined with a specialized columnar epithelium, and which is concerned with the sense of smell. The functions of the nose are phonatory, gustatory, olfactory, respiratory, and to provide ventilation of the sinuses. The last two are of primary importance.

The sinuses are hollow cavities within the bones of the face and skull. They vary in shape, size, and number in different individuals. They are all lined with ciliated epithelium, which normally secretes mucus to keep the nasal chambers moist.

In primeval man, as in lower animals, the sense of smell was of absolute necessity. The sinuses being a part of the olfactory portion of the nose, were largely distributed with filaments of the olfactory nerve, and opened widely into the nasal chambers. However, in the progress of evolution this large distribution of the olfactory nerve has become less and less necessary. The sinuses in modern man are the residual olfactory organs. Hence the sinuses are being gradually closed off from the nasal chambers, until only small openings are present. These openings are called ostia; and in the antrum or the sphenoid sinus, the ostium is high above the floor of the sinus, an unfavorable position for drainage in case of infection.

There is a well recognized physiopathological law namely, that cavities lined with mucous membrane are predisposed to inflammation, when their drainage and ventilation are obstructed. Therefore, inflammation of the lining mucous membrane of the walled off sinuses becomes a frequent pathological process.

THE SINUSES

The sinuses are divided for clinical purposes into two groups: 1, the anterior, or superficial, or so-called series I; 2, the posterior, or deep, or socalled series II. The anterior group consists of the maxillary antrum, the frontal and anterior ethmoidal sinuses. The posterior group consists of the posterior ethmoidal and sphenoidal sinuses. The sinuses are so classified because of the location of the drainage, series I draining into the middle meatus, while series II drain into the superior meatus. Consequently any abnormality in the middle meatus, as deviated septum, inflammation, or swelling around the hiatus semilunaris will interfere with ventilation and drainage of the sinuses of series I. When the same anomolies exist in the superior meatus, as hypertrophied middle turbinate, deviated septum etc., the drainage of the sinuses of series two will be interfered with.

SYMPTOMATOLOGY OF SINUSITIS

In discussing the symptomatology of sinusitis we can not present each sinus separately. As a matter of fact a single sinus is rarely affected, two or more sinuses being commonly diseased at the same time. Indeed it is not uncommon to find all the sinuses on one side of the head affected, because a, they all have a common source of infection through the nose, and b, the sinuses are so closely associated that when one gets diseased the other is affected. The maxillary antrum, however, may be affected alone, when the infection arises from a diseased tooth, and therefore is most frequently involved, though Ballenger thinks that the ethmoidal sinuses are most frequently affected. The most prominent symptom of sinusitis is pain or headaches

*Read before the Mt. Sinai Clinical Society, March 27, 1923.

caused by irritation or pressure of the trigeminal nerve endings, lining the mucous membrane of the sinuses, or in their passing through the canals.

The study of nasal headaches resolves itself into a consideration of abnormal conditions of the nasal chambers and inflammation of the adjacent sinuses. I believe it is best to discuss the inflammation of the sinuses under two headings: a, frank sinusitis, when on examination of the nose we see pus, and b, when apparently the sinuses are negative.

FRANK SINUSITIS

In frank sinusitis the headaches are severe, sharp shooting pain during the acute stage. In the chronic stage, similar pain is experienced when the openings are closed, but open only when they get overfilled with pus. The pain is mild when the ostia are open and pus is constantly discharged. In fact, in many cases headache is entirely absent. Patients will consult the clinician for sore throat, or for postnasal dropping and cough, or hawking in the morning. On many occasions patients complain only of hoarseness or laryngitis. On examination we find badly infected sinuses that are the source of the trouble, and the patient, when informed of his condition, hardly believes it to be true, as he denies ever suffering from headache or discomfort in his nose. On closely questioning, however, he will admit that some time in the past he had an attack of grippe, which in all probability was an acute sinusitis, but now in the chronic stage, with the ostia well open, there were no symptoms to attract his attention.

HEADACHE WITH NEGATIVE SINUSES

In the second class, where the sinuses apparently are negative, patients usually complain of dull headaches, yet on anterior or posterior rhinoscopy no pus is seen. The x ray is then of great aid, it will show the antrum or sphenoid cloudy, and an exploratory puncture will corroborate the x ray findings. The reason that no pus is found on examination is because, as I have stated before, the openings of the antrum and sphenoid are high above the floor of the sinus, which is an unfavorable position for drainage while the upright position is maintained. However, during sleeping hours the ostia are favorably situated and the sinuses will empty their inflammatory exudate which will escape through the postnasal space and is either swallowed or hawked out and expectorated.

There is a group of cases of this class in which the patients complain of dull headache. On examination of the nasal chambers we find no secretion and x ray examination is indefinite. Exploratory lavage of the antrum is also negative, yet the patient is benefited by the lavage, and the headache ceases. Those headaches are called vacuum headaches, and are caused by a complete closure of the sphenoid, frontal, or maxillary sinus. The air is partly absorbed by the mucous membrane lining the sinus, and the negative pressure makes the walls sensitive. Under those circumstances, if the frontal sinus happens to be involved, the headache is made worse by the use of the eyes, because the floor of the sinus has attached to it the pulley through which runs the superior oblique muscle. The use of the eyes will pull upon the sensitive floor, and headache will result. This may be mistaken for eye trouble. Being aware that such conditions of the sinuses do exist, I make it a rule when a case is referred to me for examination and the findings are negative, never to report that the sinuses are negative, but that they are apparently negative.

A general impression seems to prevail that inflammation of a certain sinus will cause pain in a definite localized area of the head, as in frontal sinusitis the pain is in the supraorbital region; when the pain is between the eyes it is thought to be significant of ethmoidal disease, and that pain in the temples extending to the occiput means sphenoid disease. However, the more one studies sinus diseases the more he realizes that this impression is erroneous. While in a small minority of cases an uncomplicated frontal sinus disease will have a predilection for the supraorbital region, and a sphenoid sinus disease for the occipital region, the reverse condition may be seen in the majority of cases. As stated before, inasmuch as usually more than one sinus is affected, pain is not confined to one area.

ETIOLOGY

The abnormal conditions of the nasal chambers that will cause headaches are:

1. Pressure of a deviated septum on the middle turbinate, irritating the nerve endings of the trigeminus, which causes headache even in the absence of sinus inflammation.

2. Irritation of the sphenopalatine ganglion. The sphenopalatine ganglion, or Meckel's ganglion, is made up of branches of the superior maxillary nerve and the vidian nerve. It lies in the upper portion of the sphenomaxillary fossa, near the sphenopalatine foramen, close to the lateral wall of the nose, and behind the nasal mucous membrane. It can readily be seen that in any inflammation and swelling of the mucous membrane of the posterior part of the middle meatus, this nerve ganglion will be inflamed and irritated.

SLUDER'S SYNDROME

Sluder, about 1908, made observations on the sphenopalatine ganglion and he was able to attribute a certain socalled neuralgia to irritation of this ganglion. That type of neuralgia is now known as Sluder's syndrome, or lower half headache. It consists of pain in and about the eye, the uppper jaw and teeth extending back about the zygoma, into the temple, the ear, the mastoid, especially a little behind the mastoid processes. Pain in the occiput, neck, shoulder, arm, forearm, hand, and fingers. Other manifestations are mustard taste in the mouth, sneezing, nausea, vertigo, photophobia and asthma. Patients suffering from this symptom complex are treated either by the internist or the neurologist, though it is now conceded by all that it is purely a nasal condition. Of course it is not necessary to have a complete picture as that given above, in order to make a diagnosis of Meckel's ganglion irritation. You may have only few symptoms of those enumerated, or even only one symptom, such as otalgia or mastoidalgia. However, if other clinical manifestations are absent, think of the possibility that the trouble is caused by disease of the sphenopalatine ganglion. The treatment in these cases consists in cocainizing the ganglion with a strong solution of cocaine. In mild cases only one treatment may give permanent relief. In moderate cases the treatment

must be repeated several times while in severe cases the injection of alcohol into the ganglion will be necessary, as in tic douloureux.

SPHENOIDITIS

Another condition which will give rise to the same symptom complex, or Sluder's syndrome, is sphenoiditis, or inflammation of the sphenoid sinus, either purulent or hyperplastic, i. e., thickening of the mucous membrane of the sphenoid sinus with or without formation of polyps. I have stated before that Meckel's ganglion is made up of branches of the superior maxillary nerve that passes through the foramen rotundum, and the vidian nerve that passes through the vidian canal. Both canals are in the sphenoid bone in close proximity to the sinus, and closely fit the trunks of the nerves. Therefore, severe inflammation of the sphenoid sinus resulting either in periostitis or ostitis, will irritate the nerves that make up the ganglion by impinging on their canals. In other words, the inflammation in this case is central to the ganglion. In such cases application of cocaine to the ganglion is of no avail. Injection of cocaine into the sphenoid sinus, or operation on the sphenoid, will give relief.

Sluder reports many cases of this type that were treated by neurologists and internists without relief, but cocainizing the ganglion or sphenoid or operation on the sphenoid gave immediate relief.

In August, 1921, a case was referred from the neurological clinic to the nose and throat clinic of the Mt. Sinai Hospital, requesting an examination and report. It was my pleasure to study the case carefully. I reported it to be a case of Sluder's syndrome and applied a strong solution of cocaine to the sphenopalatine ganglion with slight immediate relief. Two days later the patient returned complaining of the same symptoms. I again cocainized the ganglion. The patient has never returned and therefore I can not state the result. The mistake I made in this case, I admit, was that the solution of cocaine I used was not strong enough. A saturated solution of cocaine is necessary to get good results.

CONCLUSIONS

1. A great many obscure cases of headache and neuralgia present pathological conditions in the nose which are the source of the trouble.

2. A greater cooperation between internist, neurologist, ophthalmologist and rhinologist will help to clear up many obscure and perplexing headaches.

3. Rhinology of today is not limited, as many are led to believe, to spraying noses, to snatching tonsils, and to wrecking septa. It is a branch of medicine where a thorough knowledge of the anatomy, physiology, and pathology, not only of the nose and sinuses, but of the most delicate and complex part of the human economy, the nervous system, is essential.

Nasal Polypi and Sinusitis with Unique Features

ERNEST V. HUBBARD, M.D.,

New York

The following case report is presented because of its unique character, exhibiting a tic and a pus infection in one of many polypi.

Case.—Mr. G. A. H., thirty-two years of age, merchant, was referred to me for nasal obstruction. He had had typhoid at eighteen years of age, and his teeth became carious at that time. Thereafter he remained in good health until one year ago when dietetic glycosuria developed, due to excessive daily use of honey (a bottleful at breakfast time). Glycosuria ceased on stopping the honey and has not reappeared.

Six months ago, the patient told me that a few polypi were removed from the left nostril, giving much relief. Treatment was discontinued and the purulent discharge increased, always from the left nostril and with foul odor. The patient had a pronounced tic, blinking of left eye with contraction of left side of face, varying in frequency and degree. When interested and in conversation, the tic nearly ceased. Voice was very nasal at times. The right nose appeared normal; the left was badly blocked by polypi. There was a thick purulent discharge. There was no pain, but markedly obstructed nasal respiration.

Fractional operations being agreed to, one polyp was removed every two or three days, thirteen in all. A snare was used in removing the twelfth polyp complete, unbroken and with pedicle. There appeared a central globular spot in the polyp, about the size of a French pea, shining white and opaque. The polyp was the size of a raspberry and otherwise presented usual characters. Opening with a sterile scalpel revealed pus in its centre (the globular spot). It was placed in sterile gauze and submitted to Dr. J. W. Dwyer, who reported a pure culture of streptococcus hemolyticus.

The skiagraphic report made by Dr. Fred Law is as follows: Very small frontal sinuses; left showed severe, and right mild involvement. Left ethmoids and left antrum showed severe involvement. Right ethmoid and right antrum showed mild involvement. Sphenoids were clear.

In view of the great improvement in breathing and decrease of purulent discharge, the patient declined to submit to further operative procedures for relief of the sinus and ethmoid condition. When seen again, one month later, it was of interest to note the very great decrease in the tic described above. It is fair to assume that the muscular contractions were caused reflexly by the intranasal pressure (polypi) and perhaps by a toxic influence from the imperfectly draining infected sinuses.

Practical Therapeutics

QUINIDINE IN TREATMENT OF CARDIAC DECOMPENSATION*

MORRIS H. KAHN, M.D.
AND SIDNEY B. WILENSKY, M.D.
New York

The use of quinidine as a therapeutic measure in auricular fibrillation is gravitating to its own. The spectacular effects at times derived from its use gave promise which was in a measure fulfilled by longer experience. Its proper place is gradually being determined by indications and contraindications for its use. It seemed, at first, to be confined in its applicability to hospital patients. It has, however, also been used in ambulant cases and has been of distinct, although limited, benefit.

Wenckebach (1) in 1914 discovered the effect of quinidine in restoring normal rhythm in a case of auricular fibrillation. Frey (2) studied its effects and found striking results, and it is largely in consequence of his work that the problem became popular. Hoffmann (3) found in dog and cat hearts so perfused with quinidine that it became impossible to bring about fibrillation of the auricles.

Auricular fibrillation is not a direct consequence of an anatomical anomaly in the sinus node. Floystrup (4) demonstrated changes in the sinoauricular node in hearts without fibrillation; and a normal appearance of the sinoauricular node, the myocardium of the auricles, and the nervous system could be found in cases of auricular fibrillation.

It has been shown by Lewis (5) that in auricular fibrillation a circus movement exists in the auricle; that a single wave is propagated and revolves perpetually upon a reentrant path. The circus movement is repeated on the average 450 times a minute and it is this circulating wave which, in its revolution, alone controls the auricle in auricular fibrillation.

Lewis suggests that quinidine may act on auricular fibrillation by either slowing the rate of conduction of the contraction wave or by increasing the refractory period in tissue over which the wave has just passed. Thus it may prolong the refractory period to such an extent that circus movement is no longer possible. It may produce its effect also by decreasing the conduction rate and so slowing up the circus movement that the rhythmic function of the atrial muscle can reassert itself (6).

In a recent experimental and clinical study Korns (7) presents evidence which lends support to the belief that the action of quinidine in abolishing circus movement is not conditioned by the type of cardiac lesion, the degree of decompensation or the duration of fibrillation; but is essentially related to the pathological physiology of the auricular muscle.

The duration of the normal rhythm following its restoration by quinidine for the most part has been merely temporary. The more or less continuous administration of small amounts of quinidine tends to prevent the recurrence of fibrillation (8).

*From the Medical Services, Beth Israel Hospital, New York City.

The reports on the effects of quinidine on subjective symptoms and cardiac decompensation have been somewhat conflicting. Frey states that the drug exerts no favorable influence on passive congestion or diuresis. We found the same to be the case, and in four of the six cases that did not respond to quinidine, we were able to obtain some improvement under digitalis.

Sudden death, collapse, with respiratory failure, and other unpleasant results, such as embolic infarcts, have been reported. In four out of five fatal cases, the heart was badly decompensated (9). In our cases, however, no untoward effects were noted. Frey believes that lost compensation must first be restored with digitalis if possible (10). Then after a week's suspension, the quinidine may do good service. It is possible that this accounts for the relatively small proportion of successful results in our series.

In our series of seven cases we have obtained only one successful result. In the other six cases quinidine administered for a period of two to three days did not seem to be of any benefit. This is the same proportion as was obtained in twenty-two ambulatory cases reported (11). Of these, only three responded to quinidine sulphate with normal auricular ventricular sequence. Of these three, one remained regular for only a few days.

It will be seen, and this is the significant value of this report, that all of our cases were in an extreme degree of cardiac decompensation, not selected, and were treated promptly after admission to the hospital without the preliminary advantages of rest and digitalis.

In all our cases quinidine was given by mouth in two to three grain doses every two hours for a period of two or three days. Of course, in some cases smaller doses were administered as many complained of nausea and vomiting, probably due to the heart condition.

Electrocardiographic studies during the course of treatment have shown the profound effect of the drug in fibrillation. The oscillations due to the spread of the excitation wave in the auricle tend to become less rapid and larger. Frey noted that following the restoration of sinus rhythm, the T wave might become less high, the P wave altered in shape and the conduction time increased over the normal (10). In our successful case the electrocardiogram showed a sudden change to normal rhythm and the patient was discharged feeling very much improved, although edema still remained.

In the cases in which normal rhythm was not restored, there were no evidences in the electrocardiograms of any changes produced by quinidine. In the case in which normal rhythm was established, there was at first a slight increase in the ventricular rate as shown in the subjoined electrocardiograms. (Figs. 1 and 2.) The fibrillation did not seem to be any coarser and there was no evidence of auricular flutter. No premature beats were encountered.

We append brief reports of several cases to show the extent of cardiac decompensation.

Case I.—M. B., aged twenty-five. Following rheumatic fever at seventeen, she had occasional attacks of palpitation, became dyspneic on exertion, and was confined to bed for days at a time. For three years her symptoms were much worse and edema developed. She had occasional hemoptysis. Physical examination showed marked orthopnea, heart sounds completely irregular, systolic murmur present at times, pulse deficient. There was a small amount of pleural effusion, liver markedly enlarged, marked edema of lower extremities, triangular area of clouding at right hilus and clouding of right base. Urine showed many casts and much albumin. Blood chemistry showed slightly increased figures; blood pressure about 130:70. Quinidine was gives for two days. The patient's condition was still poor and there was no improvement of fibrillation. Digitalis was given.

Case II.—I. A., aged forty, had been in the hospital many times with the same cardiac condition. She returned complaining of dyspnea, cough and palpitation. Physical examination showed scleral jaundice, heart enlarged with auricular fibrillation, dullness at right base and liver markedly enlarged, marked edema of lower extremities. Urine showed albumin and granular casts. Blood chemistry figures slightly increased. X ray showed enlargement of cardiac shadow. Blood pressure about 125:80. Quinidine was given for two days. Condition not improved. Digitalis was again given. The patient died in a few weeks.

Case III.—R. S., aged forty-seven, had been in this and other hospitals several times before for her cardiac condition. She complained of dyspnea, orthopnea, palpitation and edema of the extremities and abdomen. The patient was cyanotic, heart fibrillating, systolic murmur at apex, moist râles at base, marked enlargement of liver, edema of the extremities. Urine showed albumin and hyalin and granular casts. High creatinin in blood. Blood pressure about 118:90. Quinidine given for three days. No change in condition. Digitalis was restored.

Case IV.—L. L., had had mild attacks of rheumatism recently. There was present chronic bronchitis and emphysema, auricular fibrillation, marked edema of extremities, liver slightly enlarged. Urine showed casts and albumin. Blood pressure about 170:100. X ray showed large cardiac shadow, increase of hilus markings, especially on left side extending to base. Quinidine was given one day with no change; digitalis given because the patient's condition became very poor.

Case V.—Y. B., aged sixty, complained of weakness, anorexia and dyspnea for four weeks. Palpitation for eight years previously. Orthopnea and edema of lower extremities for past few days. Physical examination showed slight enlargement of heart, irregular, fibrillating, pulse deficient, 56, edema of legs. Urine showed albumin and granular casts. Blood creatinin markedly increased—5.0. Blood pressure about 148:96. Quinidine given for three days produced no change.

Case VI.—R. S., aged forty, complained of palpitation and dyspnea for ten days. Had many attacks of swelling ankles, palpitation, precordial pain and dyspnea. Moist râles were found at the bases, enlarged heart, auricular fibrillation, edema of ankles. X ray showed cardiac shadow enlarged. Blood pressure about 110:85. Quinidine given for two days without relief.

Case VII.—N. L., aged fifty-four, complained of dyspnea and palpitation for twenty years, with increasing edema of lower extremities for six weeks. Occasional hemoptysis. Palpitation increasing past year and a half. Physical examination showed orthopnea, chronic bronchitis and emphysema, auricular fibrillation, presystolic thrill, double mitral murmur and enlarged liver with marked edema of lower extremities. Urine showed much albumin and casts. Blood chemistry figures were high. Blood

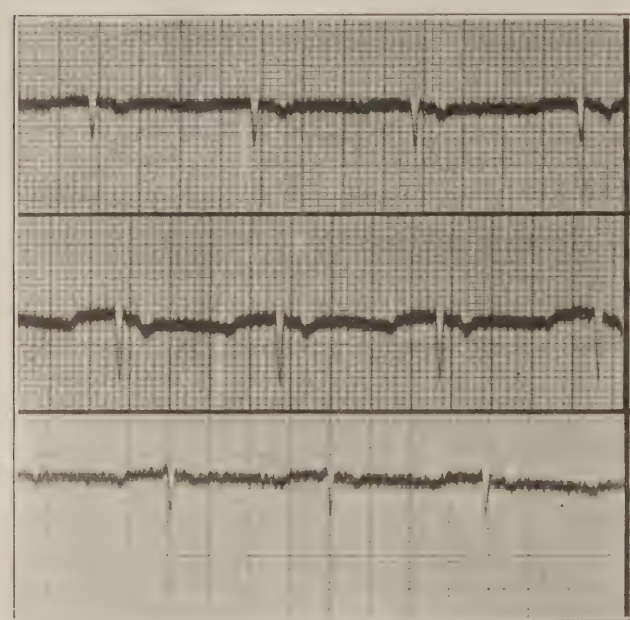

Fig. 1.—Before the administration of quinidine.

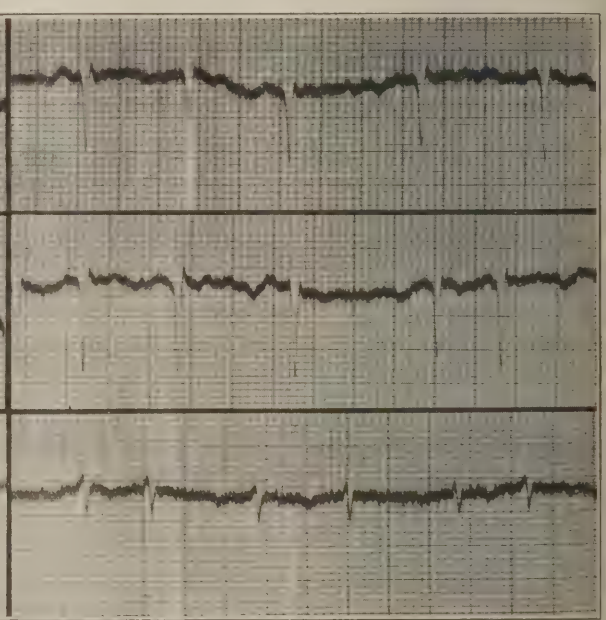

Fig. 2.—After four days of quinidine, in doses of two grains three times a day.

Wassermann test was negative. Blood pressure about 134:60. Quinidine was given for two days produced decided effect and the heart was found to be normal and regular. The edema still remained, but the patient was discharged improved. We have since been informed that two months later the patient died, apparently from heart failure.

We desire to express our thanks to Dr. J. Barsky, Dr. J. Reinthaler and Dr. D. Robinsohn, attending physicians to the medical service, Beth Israel Hospital for the opportunity to observe these cases in their wards and to Mr. Nicholas Opalonick for his technical assistance.

Oral Vaccine Prophylaxis and Treatment of Bacillary Dysentery.—A. Gauthier (*Bulletin de l'Académie de Médecine,* January 15, 1924) reports, in the first place, on prophylactic vaccination by the mouth in 29,880 persons in Greece, mostly refugees. The dose was one mil in individuals over six years of age, one half mil in children of from two to six years, and one quarter mil in children below two years. The vaccine was taken in a little water, on three successive days, at least one hour before a meal. The only untoward effects were occasional slight nausea and brief dizziness two hours after ingestion of the vaccine. The vaccines used contained three billion killed bacilli per mil, consisting of the Shiga, Flexner, Strong and Y varieties. One vaccine consisted of peptone bouillon cultures, including the exotoxins as well as the endotoxins of the germs; the other vaccine was made from agar cultures, washed, heated and suspended in normal saline solution containing a little phenol. These two kinds of vaccine appeared to give equal results, the second, however, having better keeping qualities. From the third to the eighth day after vaccination, positive agglutination occurred regularly to a maximum of 1:250 for Flexner and Shiga germs; this property persisted generally two or three months, diminishing gradually. Among the whole number of persons thus vaccinated, no case of dysentery was observed during the summer or fall, though these persons were living in endemic foci and drinking water of poor quality. A number of local epidemics of dysentery, including one of demonstrated Flexner bacillus origin, were abruptly stopped by oral vaccination. In the Kokinia epidemic among 4,800 refugees, there had been 400 cases and 50 deaths. Oral vaccination was instituted in two thirds of the refugees, the remaining third serving as controls. The epidemic was checked at once in the vaccinated group, while among the others there still occurred 194 cases of diarrhea or dysentery. Elsewhere, 340 vaccinated individuals were moved into a contaminated camp; all remained free of the disease. In the attempts at treatment of established cases of dysentery by the mouth, the dose ranged from one half mil daily in children of six months to two years to two mils on the first day and three mils on succeeding days in adults. The amount taken each day was divided into three or more doses taken at different times. The duration of treatment averaged from three or four days in simple diarrhea to seven or eight days in severe dysentery. The results obtained consisted in rapid disappearance of pain, tenderness, tenesmus and blood, reduction of the frequency of the stools, improved general condition, and markedly shortened course of the disease. The percentage of cures in 660 cases of dysentery was 95.4; in 655 cases of simple acute enteritis, 98.16; in 34 cases of simple chronic enteritis, none; in 84 cases of infantile diarrhea, 57.1, and in 20 cases of diarrhea with green stools, 45. The favorable effect of the vaccine in diarrhea and enteritis with stools bacteriologically negative for the ordinary germs of dysentery proved somewhat of a surprise.

Treatment of Anemia by Intravenous Injections of Sodium Citrate.—Normet (*Bulletin de l'Académie de Médecine,* December 27, 1923) finds that mononuclear leucocytes undergo a transformation into normoblasts and erythrocytes as a result of this procedure. Each treatment consists in injecting forty to sixty mils of a three per cent. solution of sodium citrate—0.02 gram of the citrate per kilogram of body weight—into a vein at the bend of the elbow, in two doses five minutes apart. In the favorable cases, the red cells show an increase by the next day of as much as 600,000 per cubic millimetre, and in the course of a week the increase generally reaches 1,000,000. With the injections repeated weekly, the red cell count continues to ascend, with temporary phases of diminution after some of the injections. The treatment is stopped after this sixth injection, and three weeks the final result of the treatment can be judged. By this method recovery was obtained in severe cases of aplastic pernicious anemia, with the red cells reduced to 900,000 to 1,200,000, which threatened the patients' lives and had resisted the customary treatment by arsenic and iron. The best results are obtained in anemias with a high color index. In three cases, recovery, with the red cells at 5,000,000, has been maintained for over a year. In the two of these that had greatly enlarged spleens, the spleen showed a regular, progressive reduction in size during the treatment. The failures of the treatment, aside from chlorosis, were in the anemias symptomatic of grave organic disturbances such as tuberculosis and cancer. Experiments in dogs and rabbits showed that iron may with advantage be combined with the sodium citrate, 0.1 per cent. of iron and potassium tartrate being added to the three per cent. sodium citrate solution. Intravenous injections of this solution in doses of five mils per kilogram in dogs and three mils in rabbits led to an increase of fifty to eighty per cent. in the red cells after three fortnightly injections. Return of the cells to the normal number did not occur for several weeks. These combined injections are likely to prove of great value in the treatment of pernicious anemia.

Historical Medicine

The History of Bathing

LLEWELLYN JONES LLEWELLYN, M.B. Lond.

London

Member of the Conference (Medical Research Council, Lond.), on Arthritis and Allied Rheumatoid Conditions; Late Senior Physician, Royal Mineral Water Hospital, Bath.

Man's rich restorative; his balmy bath
That supples, lubricates, and keeps in play
The various movements of this nice machine
Which asks such frequent periods of repair,
When tired with vain rotations of the day.
YOUNG.

THE ANTIQUITY OF BATHING

The writings not only of physicians, but also of historians, poets and lawgivers, bear witness that the practice of bathing is of extreme antiquity. Thus the restorative power of warm baths was recognized even in the days of Homer, who, indeed, tells us that Diomedes and Ulysses had recourse to them on their return from one of their expeditions, and again in the *Odyssey* observes that Telemachus and Pisistratus on their arrival at Menelaus's palace enjoyed their soothing influence. Here we have probably the first recorded instance of the recognition of the therapeutic advantages of warm bathing.

BATHING RITUALS

Grecian mythology abounds with similar allusions; thus, Pindar in his *Olympic Odes,* refers to the warm baths of the Cicilian nymphs, while both Aristophanes and Herodotus allude to the special veneration accorded to "natural" warm springs, all such being dedicated to the god Hercules. Leaving this region of myths and legends, we must not omit to refer briefly *en passant* to the ritual ablutions so scrupulously observed by the followers of the ancient Egyptian, Jewish, Mohammedan and other faiths.

THERAPEUTIC VALUE OF BATHING

That these ceremonial cleansings performed with such meticulous care had not, however, blinded the ancients to the therapeutic virtues of bathing, is evident from the writings of Josephus. This celebrated historian, in his monumental work, asserts that the warm baths of Emmaus were even in his day famed for their healing qualities, and from its pages we further glean the interesting fact that Herod, during his last illness, at the behest of his physicians, immersed himself in the hot springs of Callirhoe. The researches of antiquarians have indeed shown that hydrotherapeutic practice had attained to a high degree of excellence, even amongst primitive civilizations.

The splendor of the far famed baths of Darius, for example, bear eloquent, though silent, witness to the prominent part bathing exercises played in the everyday life of the ancient Persians, while amongst the Lacedæmonians, they were regarded as an essential part of an athlete's training. Again, that the Phoenicians were alive to the special advantages of the hot air bath may be fairly deduced from the remarkable discovery by Urquhart of a hot air chamber in the ruins of Baalbec.

HYDROTHERAPY IN GREECE

But while granting to these pioneer efforts their due meed of admiration, it must be admitted that they but dimly foreshadow the still more splendid achievements of the Greeks and Romans. The citizens of Athens enjoyed the luxury of both private and public bathing establishments, which indeed were attached to the gymnasia so highly prized by the Grecian youth. Nor was the therapeutic aspect of bathing overlooked, for turning to the writings of Hippocrates we learn that the Father of Medicine advocated the use of cold baths of short duration, which should, he thought, be both preceded by and followed by friction, though hot baths, he opined, might with advantage be more prolonged.

Again, as the following passage from the works of Aetius, the renowned Greek physician shows, the ancients were fully aware of the medicinal value of certain mineral springs and the beneficial effects that followed immersion in their waters. Thus he tells us that "Or natural bathes some have saltpeter in them as chief mineral and predominate of saltpeter by itselfe alone, some salt, some alum, some brimstone, some copper and some have earthpitche called bitumen. . . . . And they are good and profitable for all bodies which are moist and colde against nature and for such diseases as have long continued wherefore they are good for all kinds of diseases in the joyntes, the goute in the foote, palseyes, the diseases in the kidneys."

ROMAN BATHS

We must now pass on to that more interesting past of our historical retrospect which deals with the growth of hydrotherapy among the Romans. During the early days of the Empire, i. e., prior to the aedileship of Agrippa, no trace had yet presented itself of the colossal and sumptuously adorned thermæ, which, with the dawn of the Augustan age, were to add so much to the grandeur of the Eternal City. The baths made use of during the infancy of ancient Rome were indeed quite primitive in character, but *pari passu* with the growing prestige of the Roman power, their bathing establishments grew more and more and more pretentious, attaining the zenith of their splendor during the reign of Diocletian and Caracalla.

THE BATHS OF DIOCLETIAN

Though sadly worn by the corroding tooth of Time, the baths of Diocletian, stately even in their ruins, still remain, imperishable monuments of the skill and care bestowed upon them by the builders and sculptors of that brilliant age. Beside their vast magnitude our latter day establishments are dwarfed

to puny size, the baths of Caracalla even transcending those of Diocletian, which latter albeit reached the imposing length of 1,500 feet and were but little less in breadth. Noble and impressive as were the proportions of these historic thermæ their interior was no less magnificent, sculptor and artificer vying with each other to produce an almost barbaric splendor of adornment. Through the gaping mouths of lions fashioned of silver, the warm waters gushed forth continuously into baths, whose sides glistened with the varied hues of marble richly inlaid with mosaics, while the voluptuous patrician, scorning the use of baser metals, rested his enervated frame on seats, forsooth of silver made.

BATHING EXCESSES

That the practice of bathing was indulged in by the Romans to an inordinate extent is undoubted, and both Pliny and Seneca in their writings deplore this voluptuous abuse of an otherwise salutory custom, regarding it as a sign of that oncoming degeneracy in their countrymen, which ultimately culminated in the downfall of the Empire. Nor were they singular in their attitude towards this enervating habit in which Statius, a poet of the Claudian era, found food for one of his *Satires:*

> Nil ibi plebium; nusquam Temesae notabis
> Aera sed argento felix propellitur unda,
> Argentoque cadit, labrisque nitentibus instat
> Delicias mirata suas, et abire recusat.

To such an extent were the Romans enamoured of their baths, that, whenever their conquests led them far afield, they were wont to erect their well known thermæ; hence the ruins of which have been found in the confines of our own island at, for instance, Bath, Chester, Shrewsbury, and Cirencester.

Those ill advised excesses on the part of the Romans are all the more unintelligible when we bear in mind the quite considerable knowledge of hydrotherapy possessed by their physicians. Celsus, to wit, was familiar with not only hot and cold baths but also vapor baths, intelligently enlisting their aid in the treatment of disease. The same may be said of Asclepiades, a Greek physician who practised at Rome, and both of them, as we know, thoroughly appreciated the value of massage, also active and passive exercises.

That they showed discrimination in their "application of hydrotherapeutic procedures is evident from the works of Galen and Horace, in one of his epistles, tells us that he had occasion to consult Antonius Musa, and was advised by him to substitute cold for the warm baths he had been in the habit of taking. This same physician had the weighty responsibility thrown upon him of conducting the first Augustan emperor through a course of hydrotherapy, which happily, so Suetonius tells us, proved highly beneficial.

HYDROTHERAPY IN THE MIDDLE AGES

During the middle ages the science of hydrotherapy received its chief impetus from the Arabian physicians who keenly advocated the use of baths in fevers. Baas in his *History of Medicine* refers to the socalled bathkeepers who enrolled themselves into guilds and erected bath houses all over Europe. Here one may be pardoned a digression, in view of the interesting fact enabling us to refer to the reputed existence of a Chinese record, which asserts that many hundreds of years prior to the advent of Christ, a Chinese physician had employed cold affusions followed by packing in linen sheets, while we may add, on the authority of the *Tokio Medical Journal,* that a Japanese physician, Na Kaganu, wrote a dissertation on the medical use of baths some thirteen hundred years ago. In the fifteenth century a remarkable treatise came from the hands of an Italian physician, Michael Savonarola, advocating the systematic use of baths, and about the same time Barizzi suggested cold vaginal douches in uterine disorders.

HYDROTHERAPY IN ENGLAND

Again, in the early part of the seventeenth century, the value of cold bathing in dysentery and other disorders was insisted upon by Van Helmont and other Belgian physicians, while during the latter half of the same period Sir John Floyer's classical work appeared dealing with the right use and abuse of the hot, cold and temperate baths in England.

In 1747, John Wesley's well known work on primitive physick was forthcoming, to be followed shortly, some fifty years afterwards, by the justly celebrated treatise of Dr. James Currie which may be truly said to mark an epoch in the development of rational hydrotherapy.

Indeed as Dr. Fortesque Fox remarks, in his recent able lecture on hydrology, the remarkable evolution in hydrotherapy that took place in Austria and Germany during the nineteenth century was the direct outcome of Floyer and Currie's researches.

Within five or six years after the publication of Currie's work, his hydrotherapeutic methods were carried into effect in the hospitals of Vienna, and during the epidemics of typhus fever, which raged at that period, the victims were treated by immersion in cool baths.

FOUNDATION OF SCIENTIFIC HYDROTHERAPY

In 1830, a Silesian farmer, Victor Pressnitz by name, introduced his celebrated water cure which achieved amazing success. The systematic methods of bathing and dieting pursued at his establishment proved so salutary that before long similar institutions were erected throughout the Continent and in England at Matlock and Malvern, thus laying the foundation of our modern hydropathic cures.

Shortly afterwards, in Germany a series of experimental researches were undertaken with the object of ascertaining more exactly the effects of bathing at varied temperatures, its influence on the circulatory and nervous systems and metabolism generally. Subsequently, a large number of clinical and experimental studies on the same lines were conducted by workers in different countries especially in Austria, those of Wilhelm Winternitz, of Vienna, being justly and universally admitted to be the foundation of scientific hydrotherapy.

Here our retrospect, all too brief as it is, may fittingly cease, as with the impulse derived from Winternitz's work and labors, hydrotherapy emerged from the misty regions of empiricism into the clearer atmosphere of experimental study in which alone it can develop its immense resources.

Contributors to the Science of Medicine

FRANCOIS RABELAIS

François Rabelais was another of the world's geniuses whose true nature and real claim to greatness have been grossly misinterpreted. For nearly three hundred years, he was looked upon askance as an indecent buffoon. Then, when it was discovered that there was more than mere grossness and licentious humor in his writings, some critics went to the opposite extreme and declared that the laughter only served as a mask for a wholly serious philosophy which he was expounding. All this because it seems almost impossible for human beings to realize that we can laugh heartily and at the same time find life a very serious matter! This Rabelais was able to do; it was one of the deepest and most fundamental traits of his personality. He expressed this when he wrote:

Better is it to write of laughter than of tears,
For laughter is the special gift of man.

Rabelais's fun has been compared to that of Aristophanes It is gay, joyous, exuberant. *Gargantua* and *Pantagruel* is always open and above board, "naked and unashamed"; there is no licentiousness, no perversity, no pruriency exciting the imagination, no half revealing veils, nor innuendoes; vice is not dressed up to be attractive or enticing.

Much controversy has existed as to the date of Rabelais's birth, but most authorities now place it between the years 1490 and 1495. The place was probably the small village of La Devinière, near Chinon, where Jeanne D'Arc had her famous interview with the Dauphin. As the youngest of four children, he was destined for the cloister and probably given the tonsure at the early age of seven. He seems to allude to this, rather bitterly, when he writes in *Pantagruel:* "I do marvel whether the mothers in the other world can bear their children nine months in their womb, seeing that they cannot bear them nor brook them in their houses nine years, nay most often not seven; but by putting only a shirt over their robe and cutting a few hairs on the top of their heads, together with certain expiatory words, they . . . transform them into birds (monks) such as you see before you." He studied theology at Angers, became a Franciscan friar at Fontenay-le-Comte, a Benedictine at Maillezais, studied medicine, probably at Paris, but had degrees from Montpellier, presumably studied law at Bourges and Orléans, was a physician at Lyons, Turin, Rome and Metz. His life was one of constant change from place to place, sometimes in fear of his life, for his satirization of certain aspects of the Roman Catholic belief and practices, of Calvin and predestination, of royalty and the aristocracy, of the law courts, of some of the medical practices, and of many other phases of the life of his day which his broad and humanistic philosophy and common sense could not accept, aroused the enmity of powerful interests that never ceased their persecution during his lifetime. Fortunately he had a remarkable capacity for making warm and loyal friends who were always eager to give succor in time of need. His death probably occurred in 1553 at Paris. His last words were, *"Je vais quérir un grand peutêtre,"* a sentiment in accordance with the Rabelaisian philosophy symbolized by the quest of Pantagruel. He believed that the whole of life must be a seeking after truth and especially demonstrable scientific truth. He included in his studies botany, anatomy, and physiology in this quest of truth. Yet he firmly believed that man must go on this search, always accompanied by the "guidance of God and the company of man." Without "divine grace" and without friendship man is powerless. Yet each must interpret life according to his own imagination. "Imagine, and drink, and you will have the taste of whatever wine you imagine." But this is no lazy man's rule of self indulgence. It is like Nietzsche's stern command: "Be sure ye do whatever ye will—but first of all be such an one as *can will.*" Says Rabelais in describing the reformed education of Gargantua: "In their rule there was but one clause: Do what thou wilt; because that men who are born free, well born, well bred, conversant in honest company, have by nature an instinct and spur which always prompteth them to virtue and withdraweth them from vice; and this they style honour."

Statue of Rabelais in Chinon, France.

As a writer, without doubt Rabelais's rich vocabulary is his most obvious characteristic. This is all the more remarkable when we remember that no dictionaries had ever been published when he lived. His words are culled from all sources—languages, other writers, and his own fancy. He delights in long, rolling lists of them, and, not content with stringing them out in endless array, often draws

hem up in lines, columns, and classes, seeming ometimes to revel in the mere sound of them, irespective of meaning, in a kind of superior Gertrude Stein manner. His management of phrases is perhaps not so obvious, but even more remarkable, for his meaning almost never fails in clarity and his sentences are always cadenced. Other characteristics of his style are variety, precision, eloquence, wit and humor, and a charming naturalness, especially in recording the conversation of his characters. These are, in keeping with the mental attitude and literary practice of the times, typical rather than individual in conception and presentation. Panurge, the faithful, scholarly, rascally follower of Pantagruel, is perhaps the one exception. Throughout the writings of Rabelais are revealed his medical knowledge, his love of travel and geography, his plant lore, his broad acquaintance with the learning, manners and customs of his own times, and with the erudition of former times. He quotes and borrows from all sources, sometimes with, oftener without, any acknowledgment of the original. This, however, was a practice of the times and considered perfectly legitimate. Like Bernard Shaw, he was fond of writing lengthy prologues to his works, in which he frequently lauds to the skies himself and his opinions.

Both *Gargantua* and *Pantagruel* he declared to have been written solely to cheer and amuse his patients. As a physician, he occupied himself chiefly with one of the scourges of the day, syphilis. He followed the method of treatment of the Italian, Gaspard de Torella, by rubbing with mercurial ointment. Once, in doing some translating, he came across the description of an apparatus for fracture of the leg invented by Hippocrates. Rabelais modified and improved this, calling it a glossocomion. Another of his inventions, this time not a reconstruction, was the syringotome for incision of the peritoneum in deep lesions of the abdomen. As has been said, his works are full of medical terms and evidences of medical knowledge. The chapter on the birth of Gargantua contains many obstetrical terms and references. He knows much about hot mineral springs, argues about the possible legitimacy of a child born eleven months after the father's death, lists the anatomical organs of "Lent," comparing them to various objects common in everyday life, describes the blood in its system of arteries and veins, advocates the benefits of sleep, outlines a program of sex hygiene, and jibes at the superstitious cures of the day in the satire of Queen Quintessence. He declares that it is sinful to attribute to God or to the saints the infliction of sickness. He says that madness generally shows itself in the spring, mentions the three kinds of dropsy, and warns the doctor that the cheerfulness of his attitude or the reverse communicates itself to his patient. That the jovial cheer of his personality was a beneficial influence is shown by the large number of poems and epigrams written on the subject by friends and patients. He was well acquainted with the works of the Greek and Arabian physicians and with the pharmacopoeia of Avicenna. He made one of the earliest Latin translations of the aphorisms of Hippocrates, and was the first to lecture on medicine at Montpellier with the Greek text before him.

No sketch of Rabelais would be complete without including a specimen of his humor. One of the most famous passages of this kind is the description of the visit of Epistemon, Pantagruel's tutor, to the other world. He had been killed in battle, but was restored to life by Panurge, a procedure that he somewhat regretted because he was enjoying greatly watching the dead. "They are not treated so badly as you might think," he said. "Only their condition of life is strangely altered. For example, I happened on Alexander the Great mending old trousers, and thus earning a wretched livelihood. . . . In such fashion those who had been great lords earned their poor, wretched, scurvy living there below." Xerxes was peddling mustard, Cyrus tending cows, Nero fiddling for a living, Pope Julius selling tarts, Alexander VI was a rat catcher, Cleopatra sold onions, and Dido mushrooms. Cyrus begged a penny of Epictetus, surrounded by a gay company of singers, dancers and merrymakers, with which to buy onions for his supper. Diogenes was strutting about in a purple mantle, and felt called upon to beat Alexander the Great because he had not mended his trousers properly." George Meredith spoke truly when he characterized this delightful element of Rabelais' genius as "a veritable cataract of laughter."

And so we see the great jester, not as a mere buffoon nor yet as a subtle, ironic philosopher, but perhaps as he is described for us by one of his French biographers: the kindly friar, always joyous, *bon enfant,* holding in his lap the children of his parish and teaching them their catechism, with a sly dig now and then at theology, uncomprehended by the little ones, but for the ears of any adult friends that might be in the background; the beloved physician, who, his patients were wont to declare, could "raise from the dead," cheering the bedside with many a choice tale and anecdote; the prolific writer with remarkable literary talents and keen penetration into human nature; the student and critic, yet always with unfailing good nature and understanding, of the foibles and faults of his times, with practical suggestions for betterment implied if not definitely stated; and finally the jovial yet serious philosopher, the keynote of whose philosophy was the testing and enjoyment to the utmost of life by every human being; for it is only through the understanding and discipline gained through wide experience of the world that we can be of real service and benefit to our fellow men.

Naming Diseases.—In an article on Dr. George Cheyne and the English Malady, which appears in the *Annals of Medical History* for September, 1922, Hon. W. R. Riddell, of Toronto, says that it is an inveterate and almost universal custom to call a disease by a name indicating a foreign origin. It is difficult for the ordinary mind to look upon disease as a phenomenon arising naturally from native causes or to attribute it to anything but the hated foreigner or the act of a malign deity." The Russians call influenza the Chinese catarrh; the Germans call it Russian pestilence; the French call it Spanish catarrh or Italian fever, and also speak of gout as Italian. In the War of 1812, we called a type of influenza Canadian fever, and we have Spanish flu and German measles.

MIND, BODY, AND GOOD HEALTH

Does good health and long life depend most on the mind or the body? In this materialistic age, since the war materialism has increased, the question would be answered at once by the majority of people that health and longevity depend chiefly upon the body. At the same time, those who think deeply are becoming convinced that there is a much closer relationship between mind and body with regard to the maintenance of good health than is generally believed. Moreover, is it not possible or even probable that disease comes because mind and body are not working in harmony as they ought to work, and that in the production of disease or in its prevention, the mind plays a more important rôle than the body?

The belief which has been promulgated during recent years that diseases of the mind, that is, certain forms of mental disorder, have their origin in a bodily ailment, is receiving a great deal of attention. In fact, some clinical investigators say they have proved the point. In perfect health, it may be assumed that mind and body work in complete unison, and in disease this unison is broken. Longevity may be as much a mental and spiritual question as a physical one.

As Mr. James Douglas, a well known English writer, put it a short time ago, the secret of health may be found to reside, not in the arteries, the heart, the colon, the intestines, the kidneys, the spleen, the pancreas, the lymphatic or ductless glands, the nerves, nor indeed in any of the organs or nerves of the body, but in the spirit which controls all these organs and all the other energies and activities of the body. He points out that the atomic theory, which was made the subject of the presidential address of the British Association for the Advancement of Science this year by Sir Ernest Rutherford, a main originator of the atomic theory, has brought us closer to the secret of life. It has revealed to us the fact that in ourselves there is a universe of whirling energy which flows through our blood stream.

The secret of good health and long life, according to Mr. Douglas, lies in the coordination of the spirit and the body, and the harmony of both with the spirit of the universe. Mr. Douglas thinks that good health is to be brought about by means beyond our ken, and it is gained more by faith than reason. While medical men will hardly go so far as the English writer in believing that health and disease are dependent on the spirit alone, or rather on the coordination of the spirit and the body, few wi deny that faith goes a long way both in bringin about and preserving health.

The object of this article is to draw attention t the intimate relationship of mind and body an their influence on the health. If the mind and bod act in harmony and the ordinary rational rules o health are followed, long life is likely to be th sequence, at least, much more frequently than if th contrary is the case. The mind is probably the arb ter of health and long life as much as is the bod Optimism and the will to live will often pull a pe son through a serious illness, and of course th converse is true. And yet so far as long life i concerned, heredity plays a leading part. Many o those who have reached a green old age have bee frail and sometimes puny individuals, whose cond tions of life have not been ideal, but generally i their ancestry be probed into, it will be found tha they come of a longlived stock. Perhaps, and th is a question which might be investigated with son profit, they come from forbears who were possesse of stout courage, with the will to live. Psycholog is making great progress, and many moot points i this direction are likely to be cleared up soon. It i not well to be too sceptical of what we do not under stand. There are many things yet of which ou knowledge is elementary. It may be stated wit conviction that the influence of the mind on th body is very great, and that good health and lon life depend considerably on the state of mind.

MUSIC AS A THERAPEUTIC AGENT

Music soothes, charms and amuses some peopl but by no means all. On certain persons it has a annoying, irritating effect, while others are quit unmusical and can hardly distinguish one tune fro another. Curious to relate, many great artists an literary men of high renown are indifferent to musi or merely tolerate it. Poets even are sometime averse to music, Dante Gabriel Rossetti, for instance thought music positively offensive and Balzac an Victor Hugo hated it. Dr. Samuel Johnson was cer tainly more reasonable than these, as when Dr Burney encouraged him to believe that he migh in the course of time and with patience, learn some thing of music he replied, "Sir, I shall be glad t have a new sense given to me."

Dr. Agnes Savill, the widow of a well know London nerve specialist and herself a nerve specia ist of no small ability, has written recently a boo

entitled *Music, Health and Character.* The main object of the book is to endeavor to convince the unmusical that the sense they lack is well within their reach. And the fact which gives the book its special significance is that until Dr. Savill had passed the age of thirty she was entirely unsusceptible to the charm and influence of music and derived from listening to it only a sense of boredom. She tells the tale of her slow conversion, by way of curiosity and growing interest, to a deep love for that which had for long failed to arouse emotion and had left her soul untouched. So complete has been her conversion, indeed, that she is now able to write in the dual characters of a convert to the delight and glory of music and a physician who has convinced herself of the value of music as a healing agent. Her conversion was brought about at a concert at which she heard Busoni interpret, in his own masterly way, the études of Chopin and others of his works. In religion such a change is called sudden conversion.

The second part of Dr. Savill's book is devoted to a consideration of the effects of music on the human organism. She deals with the subject under the three heads, Physical Effects, Psychic Effects and Analogies and Practical Considerations and Applications. Dr. Savill argues and states from experience that cases of nervous troubles, known generally as neurasthenia, are frequently immensely benefited by music and, moreover, she contends that a love of music, rightly directed, can strengthen the whole character. In the words of the author, under the spell of great music a man finds that the obsession of sordid cares and anxiety fades into the background. Their true insignificance is revealed in the presence of the high emotion which raises him above his own limited personality. He loses his troubled individual self in a larger whole, and emerges strengthened, capable to cope with and overcome what had previously threatened to engulf him. He reaches out to a greater and deeper consciousness; the realization of the strength dormant within him tides him over the present obstacles and infuses fresh energy for the future. The armor of cynicism drops from the hardened man of the world; he knows, at last, that reality is as fair as the dream.

In short, Dr. Savill asserts, and draws instances from her own experience to prove, that music acts as a healing agent of which the possibilities have not yet been nearly gauged. Especially from the psychological point of view this statement can be easily believed. In certain nervous cases the effect of music is said to be almost magical, and, in any event, music is a therapeutic agent of value to those who love it, in that it takes one out of oneself and relieves the monotony of existence which sometimes in highly strung individuals threatens to be unbearable. Dr. Agnes Savill has done a great service in pointing out the value of music as a healing agent which in some cases soothes, and in others stirs the imagination and emotions.

SPORTS AND BREATHLESSNESS

For some years past, in all countries and in all classes of society, a return to Spartan customs has been highly in vogue. Muscular exercise enjoys marked favor, irrespective of age and sex. It can be rightly said that training has become a somewhat tyrannical custom everywhere. Nobody can underestimate the advantages of sports when judiciously indulged in. Not only do they develop the musculature, resistance to fatigue, and physical strength, but they also exercise a beneficial action over digestion and appetite, while at the same time they maintain the equilibrium of the nervous system.

One of the great obstacles to training is breathlessness, a form of fatigue impossible to overcome. It is dependent upon two factors, one inherent to the individual himself and resulting from defective functioning of one of the principal systems of the economy. Almost all subjects in a state of health and not too advanced in years can overcome this breathlessness by proper training. In point of fact, training is the evaluation of an ensemble of procedures which produce in the human body the maximum of work with the minimum of fatigue. The state of the health, strength, and resistance in which training places the body is termed the form. Hence the form is the object to be attained by training, which brings into play not only muscular exercise, but also that of the heart, lungs, brain, spinal cord, liver, kidneys, skin, and other organs. On the other hand, it is known that the functions of the striped muscles are subjected to the domination of the will, hence the psychic influence of training. Physical education, therefore, tends to place each subject in form by rational training.

Form is acquired by regular, progressive exercise, which must be sustained by an energetic will and daily effort. Certain rules, unnecessary to mention, preside over the development of form. In the first place, all the bodily functions must possess complete integrity and training should never be carried to the point of fatigue. A too intensive exercise produces autointoxication ending in fever from overwork, which occasionally may be a very serious matter. Integrity of these functions—respiration, circulation, and innervation—is essential for carrying out proper training, the cardiac functions being all-important.

All things being equal, and in a healthy subject, training will give rise to fatigue. In these circum-

stances, it is essential to have recourse to therapeutic measures which sustain the organism and prevent any useless organic loss, at the same time favoring the elimination of toxic products accumulated by physical exercise.

ON THE WRITING OF MEDICAL REVIEWS

No one who reads understandingly the medical magazines can help but be struck with the amount of loose thinking, sloppy construction and half baked ideas which they contain. No other type of trade journal could meet the overhead expenses and printing bills if they were conducted in the same way. Yet there exists today a superfluity of magazines bearing the imprimature of the medical profession which seem to get along someway, somehow.

As a matter of fact, medical journalism has not been standardized and at present its rewards for the most part are not sufficient to attract stable, well trained men who will make of it their life profession. As a rule the medical editor is a creation of circumstances. Too frequently he is a misfit in the medical profession and is obliged to eke out a half existence as an underpaid compiler of medical thought with which in its broad sense he is relatively unfamiliar. There are, of course, a few high class medical publications which are run as business institutions. There is also a group which caters exclusively to certain narrow specialties and looks for its support to the societies of which it is the exponent. There are also certain types of publications which are sales magazines for various chemical and instrument corporations and then too there is that wide and unclassified conglomeration of publications which have to do with various "isms and pathies." There are relatively few medical journals of the general type which really aim to be leaders of medical thought, which have a definite program to which they are committed. For the most part they are a spineless lot of pastepot and scissors followers which overload the second class mail and influence nobody.

In no other particular are they weaker than in the department of reviews. For example, the publishers send some new book which represents the work and the thought of some medical writer's lifetime. Such a publication merits careful, understanding scrutiny. Seldom does it receive this. Instead the book is handed to some medical fledgling or some office assistant who has no idea what the author is trying to say and the result is a wishy-washy review which does not tell anyone whether the book has any real value or not. There is a certain definite formula which is always followed. This is best illustrated by the following entirely imaginary book review:

A Manual of Automotive Medicine. For Physicians a other Automotivists. By Francois Patrick Kadutze fatzor, M.D., P.D.Q., A.S.S., Associate in Industr Automotivism, Johns Jeffersons Medical School; Surge to the Caduceus Garage. With an Introduction by Fo Henry, Oscar II Professor of History and Author *Out of the Trenches by November 11.* One volume 1012 pages, with 545 illustrations. New York and Pari P. Lippinston's Sons. Price $10.00 nit.

The distinguished author of this manual is t modest, since his work will compare favorably wi any other with which the writer is familiar. Th field of automotism would appear to be so well co ered that a new book would appear to be witho demand, but this is a new kind of a book, treatin the various diseases, ailments and eccentricities the automobile from a new angle and describing an classifying them. From the chapters on the prot zoal forms of the late nineties, the reader is carrie logically forward into the intricacies of subluxatio of the wrist pins, aphonia of the Klaxon and re gurgitation of the intake. The chapters on explosiv flatus of the muffler and impermeable stricture the gas feed are realistic and stimulating to though while that on stridor dentium of the gears has positive value of its own. The chapters on syno vitis of the universal joint and cylinderhead anthra cosis deserve special mention and those on generato cataplexy, engine dyslalia and tail lamp coccydyni are suggestive of Freud's more sweeping tenet The prevention of automotive presenility receive considerable attention. While the author and pub lisher have combined to present a volume of unusua excellence, both as to text matter and appearance the writer must take issue with the author's theor that enuresis of the carbureter is caused by tittila tion of the float valve. This may be *one* cause, bu others, such as nystagmus of the vacuum feed an ptosis of the butterfly valve, at least deserve men tion.

Is it not about time that medical journalism took stock of itself with a full realization of its respon sibilities, its opportunities and its necessities to th end that it may be purified, revivified and placed o the dignified plane of genuine usefulness?

TRAUMATIC HERNIA

Reference was made in a recent editorial to the subject of traumatic hernia in connection with in dustrial surgery. The New England Surgical So ciety in 1922 appointed a special committee to consider this subject and its report and recommenda tions, published recently, should be of interest:

We feel that the presentday attitude of making someone, other than the disabled individual, pay for disabilities for which no one is responsible, has been carried rather farther in the case of hernia than with most other alleged injuries.

The consensus of surgical opinion points very definitely to the conclusion that hernia as the result of a single injury or strain is of extreme rarity.

In view of the chaotic state of opinion respecting the etiology of hernia which obtains not only with the laity, but with a considerable proportion of the

profession as well as with courts and compensation boards, it seems wise to lay down certain criteria for determining what constitutes true traumatic hernia. We believe these to be essentially as follows:

1. Immediate descent of the hernia following the alleged cause, be it injury or strain.
2. Severe pain in the hernial region.
3. Marked prostration.
4. Symptoms of such severity that the individual calls attention to his condition within the first twenty-four hours.
5. No previously existing hernia at present site.
6. Trauma or strain must be adequate.

Where two or more of these criteria are lacking the case cannot be justly maintained to be one of traumatic origin. Where three or more are present, the question of a preexistent peritoneal pouch is immaterial.

Whether or not hernia in the main is or is not a disease of occupation and therefore compensable on economic or humanitarian grounds does not come within the realms of this discussion.

We, therefore, report that in our opinion this society should place itself on record as subscribing to the following:

1. True traumatic hernia is extremely rare, that is, most hernias are of very gradual development.
2. An individual presenting a claim for hernia in order to have his claim upheld must be able to furnish proof of having had at least four of the six criteria above laid down.
3. All other cases may be classed as disease either of congenital or occupational origin and are not the results of an individual injury or strain.

ARTERIAL PRESSURE IN RELATION TO LIFE INSURANCE

High blood pressure in this country at the present time is a matter with which the medical profession and also the lay members of the community concern themselves intensely. Perhaps the significance of high blood pressure has been exaggerated. It is a symptom and not a disease in itself, and yet when unduly high it is the red flag of danger hoisted to show that unless steps are taken to relieve the situation disaster will follow.

In this country and in Canada the medical examiners of the big life insurance companies are alive to this state of affairs. Many of them have realized the value of sphygmomanometry as applied to life insurance, and some of them even require all their medical officers to furnish records of blood pressure as a routine measure, irrespective of the age of the applicant or the amount of protection needed.

There has been brought out recently in Great Britain by Dr. J. F. Halls Dally, of London, a book on high blood pressure, a chapter of which is devoted to a consideration of arterial pressure in relation to life insurance. The author is of the opinion that the position of blood pressure in relation to life insurance cannot at present be regarded as satisfactorily established. He holds that a record of blood pressure in all examinations for life insurance is desirable, and by this he means a complete record, not only of systolic, but of diastolic and pulse pressures as well, in conjunction with pulse rate. He points out that in Great Britain, it is felt that not all blood pressure records are of equal value by reason of variations in personal equation of the examiners and in types of instrument, and there is considerable doubt as to the individual and statistical worth of figures furnished by large numbers of outside examiners.

To many practitioners the study of blood pressure is still a sealed book. Hence, the author suggests that in order to insure accuracy both for statistical tables as well as for separate reports, it would appear essential either for estimations to be made only by capable examiners at head and branch offices or for the companies to circulate to each of their medical referees a definite scheme of examination so as to regularize and render comparable the results, since otherwise it is too much to expect that practitioners throughout the country will universally take postgraduate courses of instruction in technic and instruments to be employed. It is certainly a reasonable stand to take, granted that blood pressure is a valuable signpost to the medical man when examining for life insurance, that the examiner should be able to take the blood pressure skilfully and correctly. While the companies in this country are more advanced in this direction than in Great Britain, it is doubtful if our country practitioners are better versed in the methods of taking blood pressure properly than their brethren in Great Britain. Then there is another point as to what weight should be attached to the results of a single examination. In some cases several examinations may be required, and, of course, one of the difficulties in life insurance work is to find sufficient opportunity for these.

As for the significance of high blood pressure there is no space in an editorial to deal with that phase of the matter. As said before, if very high it is a danger signal which should not be ignored, but in all cases the individual that is the personal equation, must be considered and this must be left to the examining physician. As Dr. Halls Dally says: Given rather more opportunity of examination in doubtful cases than is at present afforded, in proportion as diagnosis, and therefore prognosis, is rendered more certain, the protective value of medical examination is likely to be enhanced.

The really good examiner for life insurance is, perhaps, like the poet born and not made. On the other hand, another old Latin proverb is equally

applicable, namely, experience teaches. He should be a first class clinician and combined with his medical skill it is of advantage that he should be a good psychologist and business man, so as to be able to assess, with more or less accuracy, the relationship to insurance of the interwoven and complex individual, environmental, and financial considerations which directly or indirectly affect each proposal. With respect to the subject of this article the importance of arterial pressure in relation to life insurance it may be reiterated that it is a factor of moment, but that its signifiance must be left to the examiner or examiners. The point which it is desired to drive home is that the examiner should be skilful and the examination careful and of sufficient length when necessary to come to a satisfactory conclusion on the case. Also, as Dr. Halls Dally remarks, diastolic and pulse pressure should be taken as carefully as the systolic pressure.

ROYAL FREE HOSPITAL, LONDON

One of the deplorable results of the economic difficulties consequent to the World War has been, especially in Europe, inadequate provision of the upkeep of hospitals. One of the many institutions of this kind that have had such difficulties is the Royal Free Hospital of London. This hospital with a bed capacity of 240 treated last year 34,014 patients in its outpatient and casuality departments and 4,475 in its wards. It is a general hospital for the treatment of men, women and children, many of whom come from the poorer districts of London and its suburbs. Only patients who have some financial standing pay for their treatment; the poorer ones are treated free of charge, so the financing of the institution and its work must come largely from outside sources. Another method of obtaining the requisite funds is from the naming of cots and beds. It costs annually to name a cot £25, a bed £50, and to name each in perpetuity £400 and £1,000, respectively. The hospital contains a ward called Washington, after George Washington, at the request of the American Women's Club in London. The members of the club are greatly interested in this ward which contains twelve beds and twelve cots. It is their desire to name these beds and cots after famous American women, colleges or towns. It has been suggested that, since Dr. Elizabeth Blackwell was the pioneer medical woman in America, it would be most appropriate to name a bed or beds in the Washington Ward after her, especially since the Royal Free Hospital was the first hospital in England to open its doors to women medical students. Dr. May Thorne, a member of the teaching staff of the hospital, has been in this country in the interests of the cause and will establish a committee with the power to receive gifts and forward them to the Sir Francis Leyland-Barrett, Bart., honorary treasurer of the British Appeal Fund Committee. Until the American committee shall have been established, donations may be forwarded direct to Sir Leyland-Barrett.

PREVENTION OF MENTAL DISEASE

Helping to prevent mental disease through proper home care for mild cases and through free clinics was one of the most important lines of work undertaken during 1923 by the Mental Hygiene Committee of the State Charities Aid Association of New York. An outline of this work is given in their latest annual report. Such endeavors were begun several years ago, with the result that at the time of the report 3,300 patients for whom this was considered a safe procedure were paroled and are living at their homes, and many of them are selfsupporting. They are under continuous supervision, however.

Perhaps the most important step in the preventive program, however, has been the establishment of some forty free clinics for mental disease at all important population centres throughout New York State. At these clinics, persons who suspect the onset of mental disturbances in themselves, in members of their family, or in others whom them know, and patients on parole may receive medical consultation and advice, and, if necessary, assistance and social service from field agents attached to the staff of State hospitals. Last year, the report states, 13,329 visits were made to these clinics. Of these, 4,311 were made by persons who had had no connection with the State hospitals. Paroled patients made 8,587 visits. Of the total number of visits to clinics, 4,870 were first visits and 8,459 return visits. New State hospital clinics were opened during the year at Syracuse by the Utica State Hospital, and at Batavia by the Rochester State Hospital.

New clinics for mental defectives were established by the New York State Commission for Mental Defectives in Troy, Herkimer, Dunkirk, and Jamestown.

SCIENTIFIC PROGRESS IN 1923

The science of medicine bears so definite and significant a relation to general science that progress in both branches is oftentimes interdependent. Prof. Julian Huxley, of Oxford, author of *Essays of a Biologist,* has an article in a recent issue of the London *Daily Herald* in which he summarizes the scientific progress of the past year. Two lines of biological research were of particular importance in 1923 both giving increased evidence of inheritance of acquired characteristics. These studies were carried on by Dr. Paul Kammerer, of Vienna, who was recently in this country, through experimental work with newts; and by the Russian physiologist, Pavlov, who is said to have produced in one generation of mice a mental characteristic which is transmissible through several succeeding generations. Other achievements mentioned by Huxley are progress in the theory of the chromosomes, the Edinburgh studies in changes in sex, the experiments made in Paris in prolonging life by Dr. Voronoff, and the discovery in Mongolia by the American Museum of Natural History of the fossil dinosaur eggs.

Professor Huxley includes among medical achievements the placing of insulin treatment on a practical basis, the Dreyer treatment of tuberculosis, the studies of the effects on health of light, the discovery of the socalled Bayer 205, a cure for sleeping sickness, and the great progress of the year in cancer research.

News Items

Dr. Holt's Bequests.—Under the will of the late Dr. Luther Emmett Holt, $25,000 is left to the Babies' Hospital, New York, and $25,000 to the Columbia University for a fellowship in the medical department.

Memorial Meeting for the Late Dr. Biggs.—The Fellows of the New York Academy of Medicine will hold a memorial meeting for the late Dr. Hermann M. Biggs on Tuesday evening, April 29th.

New Clinic for Children.—A clinic for the treatment of kidney diseases in children has been opened at the New York Hospital under the auspices of the James Buchanan Brady Foundation. Dr. Oswald S. Lowsley, director of the urological department of the hospital, is in charge.

Personal.—Dr. Edward C. Titus has been appointed consultant in physiotherapy to the Reconstruction Hospital.

Dr. Chester F. S. Whitney has been awarded the Vermeil Medal of Honor by the French Government.

Dr. C. B. Goddard, of Johns Hopkins Hospital, succeeds Dr. George H. Bigelow as superintendent of the Cornell Bay Clinic.

Six Weeks' Course of Lectures at the Postgraduate.—The faculty of the New York Polyclinic Medical School and Hospital has organized a six weeks' course of coordinated, intensive, full time instruction, in an endeavor to cover in a comprehensive way the essential points in diagnosis and treatment in conformity with the present status of general medicine, surgery and the specialties. The object of this course is to assist the general practitioner in acquiring a practical knowledge of the more recent advances in medicine and surgery.

Harvey Lectures.—Dr. Herbert M. Evans, professor of anatomy, University of California, Berkeley, will deliver the seventh Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, April 26, 1924. His subject will be The Function of the Anterior Hypophysis. The sixth lecture was delivered by Dr. John J. Abel, professor of pharmacology, Johns Hopkins University Medical School, on Saturday evening, April 12, 1924, his subject being Physiological, Chemical and Clinical Studies in Pituitary Principles.

Postgraduate Course in Dermatology and Venerology.—A practical course in cutaneous and venereal diseases has been arranged by the Faculty of Medicine of Strasbourg, under the direction of Professor L. M. Pautrier and Dr. Jenklen. The course will be held from Monday, September 2d, to Saturday, November 8th, every day except Sundays and holidays. Further information concerning the course and a complete program of lectures and demonstrations may be obtained from Professor L. M. Pautrier, Clinique des Maladies Cutantees, Faculte de Medicine, Strasbourg.

Alien Insane in New York State.—More than ten thousand aliens were included in the 41,302 patients on the books of the State civil hospitals during the last year, according to a statistical report of the State Hospital Commission. In addition, there were 7,370 naturalized citizens among the patients, bringing the total of foreign born patients during 1923 up to 43.1 per cent. of the entire hospital population of the year. The actual expenditure of the State for its alien patients amounted to more than $5,000,000. The majority of aliens now in the State hospitals have been in the State more than five years and therefore are not deportable under the Federal laws.

February Death Rate Low.—The death rate for February, 1924, was 9.9 in 1,000, the lowest ever recorded for that month among industrial policy holders of the Metropolitan Life Insurance Company. Comparison of the month's tuberculosis death rate with that of February, 1923, shows a drop of thirteen per cent. Organic heart disease and pneumonia rates declined twenty-two per cent., and those for cerebral hemorrhage and Bright's disease, eleven per cent. and fourteen per cent., respectively. Mortality from influenza in February was approximately one fourth of last year's figure for the same month, which brought the peak of the influenza epidemic of 1923. The mortality data strongly support the belief, according to the bulletin, that mental derangement is an important factor in causing suicide. Among 1,081 suicides recorded in 1923, mental disease was definitely specified as a contributory factor in 212 cases, or in one case out of every five.

Washington Psychological Society.—The last meeting of this society for the season will be held on Friday, April 25th. The speaker of the evening will be Professor Leuba, of Bryn Mawr, whose subject will be mysticism.

Medicine and Pharmacy in a Combined Curriculum.—The University of Michigan has combined medicine and pharmacy in a seven year course leading to the degree of Bachelor of the Science of Pharmacy and Doctor of Medicine.

Insulin to Be Manufactured by Squibb.—The insulin committee of the University of Toronto, after a personal inspection of the laboratories of a number of firms in the United States, has licensed the research and biological laboratories of E. R. Squibb & Sons to make and market insulin.

Physiotherapy Aides Wanted.—Civil Service examinations will be held on May 7th and June 18th for physiotherapy aides in the United States Public Health Service. Full information and application blanks may be obtained from the U. S. Civil Service Commission, Washington.

Friday Afternoon Lectures at the Post-Graduate.—The series of Friday afternoon lectures at the New York Post-Graduate Medical School and Hospital will be brought to a close on May 2d by a lecture by Dr. Edward W. Peterson on A General Consideration of Surgery in Children With Special Reference to the Most Important Abdominal Affections.

Master Dermatologists.—Dr. Herman Goodman is scheduled to deliver a talk on Master Dermatologists, Based on Diseases Named After Them, illustrated by original contributions and a series of lantern slides, before the Section in Historical Medicine of the New York Academy of Medicine, Thursday evening, April 24th. Visitors are invited, and discussion will be open.

Cancer Death Rate.—New York has the highest cancer death rate in seven States, according to a report of Dr. George A. Soper, managing director of the American Society for Control of Cancer. While the average mortality rate is 83.4 in 100,000 population, New York's rate is 101. Albany has the highest city rate, with 144, and Yonkers the lowest, 86.9. New York City's is 94.3.

Hospital Equipped With Radio Facilities. — The Bergen County, N. J., Masonic Institutional Association has offered to build an entrance arc to the County Tuberculosis Hospital grounds, to give radio equipment to the hospital and to wire and equip the 100 rooms in the proposed new addition, so that each patient can plug in and get the radio entertainments while in bed.

Age no Guarantee of Immunity to Diphtheria.—That diphtheria may be contracted even by the aged was illustrated by a case recently reported to the Department of Health. The patient was eighty-four years of age and presented marked clinical symptoms with positive findings, on throat culture. Antitoxin was administered and in twenty-four hours the patient seemed to be on the road to recovery when facial erysipelas suddenly developed and the patient died.

Conference of Industrial Physicians.—The tenth anniversary meeting of the Conference Board of Physicians in Industry was held in New York last week. Addresses were delivered by Surgeon General H. S. Cummings, of the United States Public Health Service, and President Samuel Gompers of the American Federation of Labor. Others who addressed the convention were Dr. J. J. Moorehead, chairman of the organization; Dr. W. H. Park, president of the American Public Health Association; Dr. E. Livingston Hunt, professor of clinical neurology at Columbia University; Dr. O. P. Geier of Cincinnati, and Dr. W. Gilman Thompson of New York.

Quinine Needed to Fight Malaria in Europe.—Estimates received by the Health Section of the League of Nations here indicate that Russia needs over 660,000 pounds of quinine to fight malaria this year. Only 110,000 pounds will be available, and this acute shortage is hampering the systematic efforts of the Ceneral Health Department to check the epidemic. In the district of Orechovo-Zujewo eighty per cent. of the children are said to be infected, in the governments of Voronege and Briansk, thirty per cent., and in the government of Rostov, fifteen per cent. Nearly 350 out of every 10,000 people in Russia had malaria last year. In one district, the German Commune on the Volga, 44,600 out of every 100,000 of the population were infected. Malaria is also rapidly spreading in Greece where it is estimated 40,000 pounds of quinine will be required before the end of spring.

Saint Elizabeth's Hospital

WILLIAM A. WHITE, M.D.,
Washington, D. C.

The recent history of the care of the socalled insane and of the development of hospitals for the insane is an interesting one and is rapidly becoming of significance and importance to general medicine.

Following the period when the "insane" were entirely misunderstood and cruelly treated or neglected there came the philanthropic period, during which an attempt was made to rescue them from this cruelty and neglect and during which the great public institutions for their care grew up in this country. This movement occupied the larger part of the nineteenth century and in fact is still going forward. The institutions fulfilled their rescue function admirably and developed great public usefulness. They were, for the most part, built in country districts on large tracts of land and were advantageously located for providing plenty of outdoor life and farming activities for their patients. They were conducted largely along domiciliary lines and incidentally developed a fair degree of therapeutic efficiency. The whole movement, however, had little scientific background and because of the peculiar character of the problem and the isolation of the institutions those who were engaged in the work had few contacts with the general medical profession.

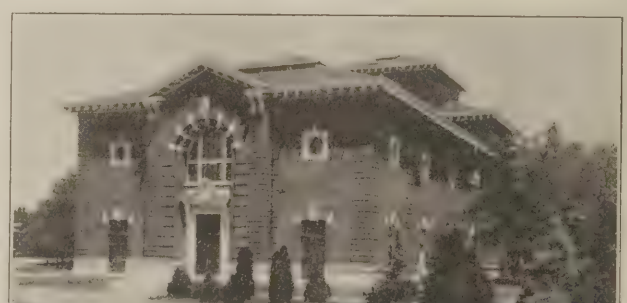

FIG. 1.—Hitchcock Amusement Hall

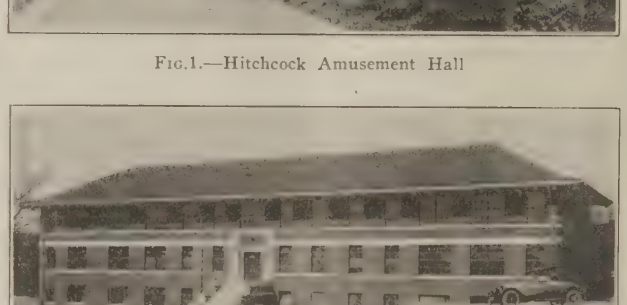

FIG. 2.—The New Blackburn Laboratory. Just being completed. Will house general pathology, neuropathology, serology, psychology, röntgenology, bacteriology, chemistry and metabolism laboratories, and is equipped with amphitheatre, lecture rooms and laboratories for student instruction.

Following this period there developed, in the last portion of the century, a movement to pattern the hospitals for the insane after the general hospitals. The armamentarium of the general hospital was therefore installed—operating rooms, consulting surgeons, dispensary service for eye, ear, nose and throat conditions, dentists, training schools for nurses, and the like. The real impetus that was back of this movement was a feeling that if the patient's physical condition were adequately known, if the state of his organs and their functions could be sufficiently investigated, the riddle of mental disease might be solved. There had been a similar attempt twenty-five years before, when as a result of similar motives, searching investigations were instituted into the pathology of the brain, particularly the cortex, in the hope that systematic serial sections of the brains of the insane would somehow discover the secret.

Making the old State hospital over into a general hospital, however, no more solved the problems of mental disease than did increasing refinements of microscopic examination insure the discovery of the physical basis of a delusion, and these movements expended themselves in producing considerable improvement in the care and the treatment of patients, particularly by bringing a more intelligent caretaker, namely, the trained nurse, to the task, and by insuring a more scientific care of the definitely physically ill in these institutions.

And now comes the next movement in the care of the insane which it is my purpose to illustrate by Saint Elizabeth's Hospital.[1] This movement had its inception in the appreciation, for the first time, of the real nature of mental disease, of its relation on the one hand to physical disease, and at the other extreme its social manifestations—its relation to the comunity—and in between, the importance of understanding the psychological factors, not only descriptively but interpretatively—the importance of psychogenesis. A real appreciation of what mental disease means, not only as it applies to the individual patient, but as a social problem, has resulted in the realization that its treatment is not confined to any one particular method—that in fact the machinery for the treatment of mental disease must needs be the most extensive machinery in the practice of medicine and must include not only all of the ordinary resources of medicine and surgery as such, but in addition all the resources of psychotherapy and the social psychologist.

The tremendous extent of the problem, and the very great cost of bringing to bear, in any one institution, all of the agencies that are now regarded as essential or desirable for the treatment of this class of patients, makes it a condition precedent that the institution should be a large one. Saint Elizabeth's Hospital is an institution with somewhat in excess of four thousand beds and from my experience I very much doubt if an institution materially smaller could command all of these resources. I mean this state

[1]St. Elizabeth's Hospital is a Federal institution, a Bureau of the Department of the Interior, of which Dr. Hubert Work is Secretary

FIG. 3.—Airplane view of the main body of Saint Elizabeth's Hospital. To the right centre the building with the clock tower is the Administration Building. Just over the top of this tower is the Amusement Hall. To the left can be seen the stack of the power plant, which bisects the prison building, beyond which is the aviation field. In the foreground, to the left, are the semipermanent buildings, constructed for the war emergency.

nent in a very concrete and practical way. Inasmuch s of necessity the largest percentage of our patients re chronic patients who are cared for on the domiiliary plan, we are able to give our acute patients nd the acutely ill care in what might be called highowered departments of the institution where the er capita per diem cost is comparable to that in a eneral medical and surgical hospital running all the ay from five to seven dollars a day. Because of the rge number of domiciliary patients, however, a cost f this sort is so distributed that the per capita of he whole institution can be kept within the bounds at will reasonably insure sufficient appropriations. A much smaller institution, without such a large ackground over which to distribute the cost of inensive therapeutics, would develop an average per apita that would make the obtaining of adequate ppropriations practically impossible.

With this brief introduction I will now give a tatement, also briefly, of the makeup of the imortant departments of the hospital and follow with ome pictures of the more important types of ctivity which will largely speak for themselves. The organization chart shows these activities more n detail.

In the first place it will be noted that the hospital s divided into two administrative functioning arts. The one represented at the left of the chart, nd which is presided over by the first assistant phyician, contains all the strictly medical and scientific activities, while the one at the right, presided over by the administrative assistant to the superintendent, contains all of the business and financial activities, including the physical upkeep of the institution.

It will be noted further that the main features of this organization are, aside from its separation into various specific activities, first, that the medical administration as such is, as far as possible, separated from the highly specialized medical and scientific activities, and that the several activities, professional and scientific, instead of being diffused indefinitely, are concentrated in special departments.

In regard to the medical administration, the hospital is divided into several services, each one of which is presided over by a senior assistant physician, whose main qualifications are his administrative ability and his psychiatric experience. These services are correlated and integrated by the clinical directors, one male and one female, each one of which, through the service heads, supervises the care of all of the patients on his or her side of the house respectively.

The strictly professional and scientific activities are grouped as follows: All of the intensive work addressed to the mental condition is handled by the department of clinical psychiatry, with a chief and associates. The psychiatrists, who have specialized in psychotherapeutic procedures, being relieved, as is not usual in institutions of this sort, from the large burden of administrative duties involving numerous letters, notes and discussions with rela-

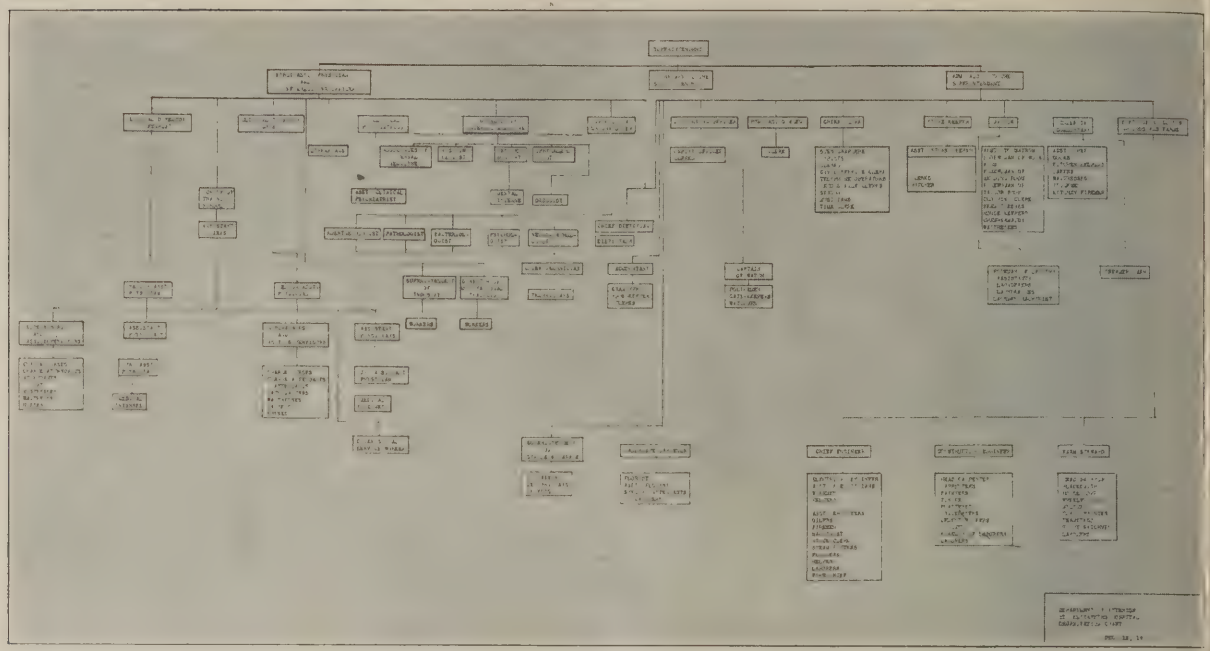

FIG. 4.—Organization Chart of Saint Elizabeth's Hospital.

tives, are thus able to devote themselves intensively to the problems of therapy.

The problems of physical illness are grouped in the department of internal medicine, which is headed by a chief and associates. This department is centrally housed in a building of 140 beds capacity, which is equipped and run precisely as a general hospital. To this building everyone who is physically ill and requires medical or surgical attention is transferred. The department of internal medicine has also the responsibility of the care of the tuberculous and its activities are being extended to cover the improvement of the care of what have in the past been called infirmary cases.

The laboratory activities are grouped together under a director of laboratories.

An outpatient department with headquarters in the city looks after patients on parole or for whom parole is contemplated and assists directly and through its contacts with other social agencies in the return of the patient to his family and in his necessary social readjustments.

In addition to the above and to the training school for nurses, which is similar in its organization and activities to training schools in state hospitals, there is a special school of instruction for attendants, and last year there was organized, with the cooperation of the Veterans' Bureau, a course of instruction in neuropsychiatry for equipping the physicians who are to be stationed in the Veterans' Bureau neuropsychiatric hospitals. At this date forty-four physicians have finished the course. In addition to this, the hospital has trained, during the past year, some thirty nurses and the same number of social workers, also for the Veterans' Bureau.

In addition to all of the features mentioned above there is a special department addressed to the care of the Veterans' Bureau patients and which is at present being financed by the Veterans' Bureau, although under the control and management of the hospital. The reason for this is that the immense influx of Veterans' Bureau patients, approximately one thousand, was too great to be wholly cared for by the hospital on the basis of its usual appropriations.

There is also maintained at the Hospital a Red Cross unit, which functions largely as a social and recreational centre and has attached to its personnel an athletic director who trains the patients in various athletic pursuits, games, etc. The Red Cross unit serves the hospital in addition through its home service section in contacting with patients and their relatives outside the District of Columbia.

The hospital publishes a monthly journal of about sixteen pages called the *Sun Dial,* which is distributed to the patients, containing information and reading matter considered appropriate and helpful and inviting contributions from them. In addition to this there is a circulating library which maintains in constant circulation approximately 2500 volumes among the patient population. This is in addition to the medical library which is composed, in the main of reference works and the current journals of neurology and psychiatry but which also contains the entire catalogue of the Surgeon General's Library and the medical section of the Library of Congress both of which are accessible to the medical staff.

As will be seen by the chart there is a fairly extensive occupational department which employs occupational therapists and undertakes gradually to project the patient into progressively more useful work which can ultimately be utilized after his discharge from the hospital. This includes definite instruction in a number of branches and there is a division in the library devoted to books on the various vocations.

At this date the hospital has 4,136 patients and 1,285 employes, including some fifty physicians. It maintains active liaisons, through medical officers with the Army, the Navy, the Public Health Service and the Veterans' Bureau. It has arrangements for an exchange service of nurses and is making ar-

angements for exchange of interns. Approximately 725 of the employes, including nurses, ttendants, psychiatric aids, occupational aids, and ietitians are employed in the direct care of the atients on the wards. The other 560 employes nclude engineers, electricians, carpenters, plumbers, abinet makers, wheelwrights, bricklayers, firemen, teamfitters, machinists, gardeners, farmers, laborers, tc., to look after the general upkeep of the hospital, he making of repairs and improvements, and the are of the roadways and grounds. The hospital xpends two and a half million dollars a year, and ast year cared for 4,927 patients, at approximately ive hundred dollars per annum per patient.

Foreign Correspondence.

PARIS LETTER

(From our own correspondent)

PARIS, *March 17, 1924.*

MEDICAL ETIQUETTE

Questions concerning the etiquette of the medical rofession are to the fore at present. They relate nore particularly to the contribution of articles to nonscientific publications and to whether it is derogtory to ask Parliament to liken physicians and surgeons to butchers and bakers. The latter matter is f more immediate importance, as a bill is under onsideration which enumerates the trades and industries that are to be protected against eviction by ndlords. The bill is a consequence of the housing risis brought about by the war. Since 1914 virtually o houses have been built in Paris, while the population has increased enormously. Since the Armistice any bills have been introduced to prevent the orcible eviction during a term of years of tenants ho, if turned out into the streets, would have been nable to find shelter. The bill at present before arliament seeks to safeguard the interests of merants and manufacturers who rent their business remises. The Syndicat des Médecins de la Seine, ie medical defence association, has voted unanilously, and has transmitted to the Senate, a resolution asking that such security of tenure should be xtended to physicians and surgeons. The old school f doctors tends to decry comparison with grocers nd plumbers, but the younger school merely shrugs s shoulders. It points out that considerations of iquette must go to the wall in this instance, and that e question is not merely professional but has a ociological bearing. If a doctor, after building up practice during ten or fifteen years, can be evicted mmarily because his landlord refuses to renew his ase in order to rent the apartment or surgery to a erson offering higher rental, he must face ruin. In e first place, it is materially impossible to find her premises; in the second, should a miracle hapen and an apartment turn up, it would be situated another section of the city where a new practice ould have to be built up. Some sections might main indefinitely without a medical practitioner. onsequently, it is to the general interest that a physician should be looked upon as a merchant and a surgeon as a manufacturer.

SIGMA VANQUISHED

Dr. Maurice de Fleury, member of the Académie de Médecine, has raised the other point, is it proper to announce in a lay review or magazine the discovery of a new remedy, thereby raising certain hopes among certain patients? He replies in the affirmative in this specific instance, and in the *Revue de France,* under the title Sigma Vanquished, he publishes an article setting forth the latest progress in combating syphilis. Because of the prevalence and social importance of venereal diseases, Dr. Maurice de Fleury holds the opinion that articles such as the one he has contributed to a review of standing—the *Revue de France* may be compared with the *North Atlantic Review*—have an important educational value. In his contribution he deals principally with the researches of Professor Ernest Fourneau, of the Pasteur Institute and his colleague at the Académie de Médecine, well known for his discovery of stovaine. For years Professor Fourneau has taken up the task of the systematic revision of the researches of Ehrlich and the Frankfort Institute. He devoted particular attention to atoxyl, which Ehrlich had set aside as causing nervous and other troubles. Professor Fourneau and his pupils first ascertained that these troubles were due to impurities in atoxyl, after which they proceeded to a systematic study of phenylarsenic acid and its derivatives. The outcome of years of research, controlled by chemical, physiological and clinical experimentation, was acetyloxyaminophenylarsenic acid, known also as 190 or stovarsol. Fourneau in English means stove, and the professor translates his name to label his discoveries.

It is claimed for stovarsol that it has a curative effect similar to that of arsenobenzol and that its value is more particularly preventive. For this reason Dr. Maurice de Fleury holds that the general public should be immediately advised of its existence. All the more so, he argues, because stovarsol is introduced by the mouth, in the form of tablets or pills, usually of 0.25 grams. In the laboratory hundreds of animals have been inoculated and all those which were not given stovarsol showed symptoms of the malady in full development. Those to which stovarsol was applied soon after inoculation were completely preserved. Two young doctors volunteered to be inoculated by scarification. The same evening and the next day they took stovarsol (the normal dose is four tablets before a meal). Simultaneously two apes were inoculated in the same manner but were not given stovarsol. The apes became syphilitic; the doctors show no symptoms of the disease. Other experiments with human subjects have been made, notably at the Cochin Hospital with thirty-three women. In conclusion, Dr. Maurice de Fleury asserts that "the prophylaxis of syphilis is an accomplished fact."

SOME STATISTICS

Coinciding with the publication of this article, statistics have been printed here relative to the prevalence of syphilis. It is generally conceded that since the World War the rural districts of Europe

are as infected as the cities, which was not the case before. M. Bayet, a Belgian authority, estimates that in his country ten per cent. of the population is affected. At the beginning of the century the proportion was five per cent; it is admitted, however, that improved methods of diagnosis have had their influence in doubling the figure. In Germany the statistics available are still those dating from before the war—eight per cent. of merchants, seven per cent. of laborers, twenty-five per cent. of students. In France Dr. Leredde calculates eighty thousand deaths a year; the number of children born with the taint and who survive is one hundred thousand, while forty thousand die before the age of five years.

SURGEONS FIGHT DUEL

For some little time after the war, duelling was looked upon with disfavor in France. Gradually the practice has been resumed. A surgeon always attends an encounter in his professional capacity, but it is rare that surgeons should themselves fight. There was an exception recently when Professors Broca and Cunéo, armed with swords, faced each other on a lawn at Chantilly, some distance from the capital. Both men are leaders in their profession in Paris and both are past middle age. Professor Cunéo, in the seventh bout, received a slight wound in the forearm and the duel ended. The motive was kept secret, but it is understood that it related to the selection by Professor Broca of his son-in-law as house surgeon of a new hospital. Nepotism is freely charged in the medical profession in this country, where it is the custom to marry "in the profession," as one might say. There are innumerable instances of the favorite pupil of a professor marrying his teacher's daughter. There is a feeling that, in addition to winning a wife, the pupil has the advantage of his father-in-law's influence in his future career.

LONDON LETTER

(*From our own correspondent*)

LONDON, *February 17, 1924.*

MIMICRY OF DEATH

In continuing her series of lectures to women students on Respiratory Exchanges at the London School of Medicine, Professor Winnifred Cullis showed how nature adjusted balance by such methods as yawning, which supplemented the lack of oxygen requisite to the tissues. Professor Cullis drew attention to the need of increased oxygen for all bodies in a state of work. Violent shivering was the automatic response to this incessant demand of the tissues for oxygen. The human body was really similar to a motor car engine, and it was quite possible to calculate the amounts of energy required to be delivered so that a man could be able to remain in perfect health and do work. The absence of oxygen had been found again and again, in animals, to produce a slowing of breathing that was very similar to the state of death. At times a hibernating animal did not take a single breath for a period of fifteen minutes, and it seemed that death had intervened, but warmth had brought the animal back to life.

ALCOHOLISM AMONG PROFESSIONAL CLASSES

According to the tabulation of the Registrar General for England and Wales, "the upper and middl classes" consist chiefly of professional men an clerks. Their comparative mortality figure range from 506 to 863, and has a distinctly lower averag than that of the other social classes. In spite o this, their alcohol mortality is nearly twice as grea as that of the skilled industrial workers. Whil the alcohol mortality of the first three divisions o skilled workmen was seven, ten and thirteen, tha of the corresponding divisions of professional me and clerks was fifteen, twenty-four and twenty-two The three groups with a general mortality of les than six hundred consist of schoolmasters, bank offi cials and of civil service officials and clerks. Thei alcohol mortality is twelve, seventeen and seventeen respectively, so that the schoolmasters alone are com parable in alcoholic restraint, to the average skille industrial worker. Best of all is the group of clergy with a general mortality of 443 and an alcohol mor tality of four.

The division which has a comparative mortal ity of 600 to 699 comprises railway officials, build ers, doctors, lawyers and artists, and their alcoho mortality is sixteen, twenty, twenty-seven, twenty eight and thirty-one, respectively. That is to say, th lawyers and doctors, whose professional duties teac them daily the evils of alcoholism, are themselve among the greatest sinners. Dr. H. M. Vernon, wh read a paper on the subject at a meeting of the So ciety for the Study of Inebriety on January 8th las an abstract of which was published in the *Medica Press and Circular,* February 13th, notes that th percentages of alcohol mortality and general mor tality have an average value of 3.2 for the shop keepers, or the same as that observed in the pro fessional classes. It is twice the percentage alcoho mortality observed in the skilled workman and al most twice that in the unskilled workmen.

What, then, are the causes of these great differ ences? First, the workmen have to pursue occupa tions which are chiefly of a muscular character, an are often carried on in the open air. On that accoun they maintain themselves in a better physical condi tion than the professional men and shopkeepers, an can less readily afford expenditure on alcoholi liquors. But the main reason, Dr. Vernon believes for the difference between the alcoholic mortality o workmen and of the other two classes is due to th form of intoxicants indulged in. The workma takes his alcohol in the form of beer for the mos part, while the professional classes and the shop keepers take theirs in the form of spirits. As spirit contain eight to ten times as much alcohol as coo beer, it is much easier to introduce excess of alcoho into the system. Again spirit drinking is easily in dulged in at all times of the day by those who ca afford to keep a supply of spirits.

RESEARCH IN ANIMAL DISEASES

It is proposed that chairs of comparative patho logy be established in the medical schools in th country in order that medical research workers ma cooperate with veterinary research workers to th benefit of the community at large. The recent costl epidemic of foot and mouth disease has brought t

he front again and emphasized the need for such ooperation. The great stumbling block to effective nedical research here is the lack of funds to prose- ute it with fair hope of success. Investigations in his direction were undertaken by Professors Muir nd Beattie some years ago, but they were discon- inued not because satisfactory results were not being ttained but because the government would not sup- ly sufficient money to continue the work in a proper nanner. Another example of the indifference of overnmental departments to medical scientific re- earch is that of Johne's disease of cattle and sheep, disease which may also affect goats and other orned animals. Up to 1910, in spite of official in- estigations carried out, no success had been reached n cultivating the specific bacillus causing the disease, r of producing a vaccine by which the disease might e diagnosed in its early stages. In 1910, however, n investigation was begun at the Brown Institution, Jniversity of London, and successful results were oon obtained. The causative bacillus was cultivated n a specially prepared artificial medium, and a re- iable diagnostic vaccine made for testing suspected nimals. The Brown being a poor institution all vailable funds were quickly exhausted and an ap- eal was made to the Development Fund Commis- ioners for a grant to enable the work to be properly ompleted. The commissioners, however, declined o make any grant and Dr. Frederick W. Iwort, uperintendent of the institution, applied to the board f agriculture with a view of obtaining a grant from he development fund, as the board acted as advisors o fund commissioners. Again the reply was un- avorable. The vice-chancellor of the University of ondon then made a further application through the oard of agriculture for a grant from the fund in id of research work in animal diseases carried on t the Brown Institution. This was refused, as well s a later application made by a deputation from the Jniversity of London. As a result of these refusals was impossible for the investigations on Johne's isease to be completed in every detail.

Work on other animal diseases has had to be rtailed through lack of funds, and according to r. Iwort it is not now possible for an independent orker to carry out an investigation entailing con- derable expense and he goes on to point out that comparison with this treatment it should be noted at the official workers of the board of agriculture, ho had taken no part in the successful experiments Brown's Institution, received considerable grants r investigating the disease. It appears from replies ven to questions on the subject in the House of ommons that the board of agriculture has no de- re to encourage independent investigations. It ands to reason that if the government desires to sist in the solution of the problems of foot and outh disease they must be prepared to give sub- antial financial support to independent investiga- ons, and in the opinion of Dr. Iwort this can be st done by endowing the posts of competent bac- riologists attached to a university or failing a finite endowment, it is essential that the worker all be assured of a regular annual grant for not ss than ten years and that he shall be left undis- rbed during that time, so that he may give all his oughts and energy to his experimental work.

This latest epidemic of foot and mouth disease has cost in the neighborhood of three million pounds paid in compensation for slaughtered animals, slaughter being the only means known at present for stamping out the disease. This is obviously a penny wise and pound foolish policy and it would certainly pay the government better by far to expend money freely in research work. It has been suggested, perhaps proposed, the writer is not certain, that either the sum of £50,000 shall be offered as a prize for the discovery of the germ or virus of foot and mouth disease or that an island should be set aside for research and that ample funds for equipment and remuneration of workers should be supplied. The problems connected with foot and mouth disease and a host of other human and animal diseases which are, or believed to be, caused by a minute filterable virus, poliomyelitis is caused by such a one, are among the most difficult problems that now confront the bacteriologist. Of course, these problems will take long to solve, but if success were to attend these efforts, the greatest advance in the control and perhaps wiping out of contagious disease will have been made. The establishment of chairs of comparative pathology is an encouraging forward movement, but these chairs must be well endowed and for this much money is required.

VOLUNTARY AND STATE HOSPITALS

The death of Sir Napier Burnett has been a blow to the voluntary hospital system. He was one of its chief supporters and being an excellent organizer his position as director of the Hospital Service of the British Red Cross Society gave him opportunities for making use of his organizing capabilities which it may be said he employed with good effect. His last report on the provincial hospitals of England and Wales—he had nothing to do with the London institutions—showed that they were improving greatly from the financial viewpoint. However, with the advent of a Labor Government, it is expected that a great deal will be heard of state controlled hospitals. In Norwich, a provincial city with a population of 130,000, there has been held recently a meeting to discuss voluntary and state hospitals. The arguments in favor of state hospitals were advanced most strongly by Dr. Cooper Pattin, medical officer of health for Norwich. He contended that it was the duty of the whole community to look after its ailing members. This duty ought to be taught in the schools and in the homes. He thought it was very good of people to subscribe to voluntary hospitals, but the number who did so was limited and their subscriptions constituted an unfair taxation of the few. He was in favor of hospitals being run by the state in conjunction with the local authorities and thought a perfectly satisfactory solution of the problem might be arrived at on that basis. The method, of course, would be to form a hospital committee of the local authority with the power to coapt members having specific knowledge or special interest. From his experience he believed as efficient and economical management could be obtained under a combination of state and municipal authorities as under the voluntary system. For the voluntary hospitals it may be said that schemes put into force to raise money have been as a rule successful. The

contributory scheme has been quite successful. Better methods of organization suggested by the late Sir Napier Burnett have effected great improvements. But the chief point to be urged in support of a continuance of the voluntary system is that state control, according to its opponents, generally means dry rot, brought about by too much red tape. The results obtained by independent investigators, as mentioned in a previous part of this letter, are better than those obtained by state officials. It is argued that state control tends to destroy initiative and it would certainly seem from the medical man's point of view that such control is undesirable. While it has been obvious for long that the voluntary system unchanged cannot continue, there appear to be no valid reasons why this system modified and with the best features retained should not be continued. Paying wards might be introduced everywhere, as it must be understood that hospitals are no longer for the indigent alone but for almost all classes of society. Why should not patients pay according to their means and then the rate burdened inhabitants of cities would not have an added burden for the up keep of hospitals from which they derive no direct benefit. The working man is not the poor man as he was when hospitals were founded. If a person paid for hospital treatment it would help to foster that feeling of independence which is too little in evidence at the present time.

WASHINGTON LETTER

(*From our own correspondent*)

WASHINGTON, D. C., *March 24, 1924.*

Somebody said the other day that Washington has a highly developed sense of rumor, and just now what has hitherto been an endemic in the larval stage has suddenly blazed forth as an acute epidemic. A physician commenting on this condition, said, "It's so bad that it's safer to give out a whiskey prescription than to order mineral oil!" All joking aside, the entire political situation has little interest for the average citizen, and the medical profession is quite untouched. It should be a credit and source of gratification to us that in the investigation of the Veterans' Bureau, whose function is nine-tenths medical, the finger of suspicion never even wavered in the direction of the Medical Division.

All of this by way of making our bow to the other letter writers of the MEDICAL JOURNAL AND RECORD and to the readers thereof, and assure them that so far as the medical world of Washington is concerned, there are no investigations.

CAUSTIC LEGISLATION

To safeguard the distribution and sale of certain dangerous caustic or corrosive acids, alkalies, and other substances in interstate and foreign commerce, Mr. Griest introduced, on March 11, 1924, a bill (H. R. 7822) to be known as the Federal Caustic Alkali or Acid Act 1924. After defining "dangerous caustic or corrosive substance" and "misbranded parcel, package or container," the bill requires labelling with the name of the article, the name and address of the manufacturer, seller or distributer, the word "Poison" in twenty-four point size, uncondensed gothic letters and directions for treatment in case of accidental personal injury by any dangerou caustic or corrosive substance. Penalties are pro vided for infractions of the act which is to b enforced by the Secretary of Agriculture.

CHILD WELFARE PROGRAM

After several months of research and publi hearings, the District Commissioner on public wel fare legislation has completed the draft of the firs of several measures dealing with social welfare wor in the District of Columbia. This first bill create a department of public welfare to supplant existin boards governing welfare agencies and, if approve by the Commissioners of the District of Columbia will be forwarded to Congress for action. It is ex pected that it will be followed by a bill providin for aid for dependent children in their own home and another making school attendance compulsory These three, if enacted into law, will form the firs section of a model child welfare code for the Distric The chairman of the Subcommittee on Social Wel fare of the District of Columbia Committee of th House of Representatives has promised prompt con sideration of the bills.

SURGEON GENERAL CUMMING DECORATED

On March 18, 1924, Mr. Moore of Virginia in troduced House of Representatives Joint Resolutio 22, providing that Surgeon General Hugh S. Cum ming of the United States Public Health Service b authorized to accept and wear the decorations o Officer of the Legion of Honor of France and th Order of Polonia Restituta, Grade Commander o the Star. The resolution was referred to the Com mittee of Foreign Affairs. A similar bill was intro duced in the Senate by Senator Swanson o Virginia.

TO REGULATE CLINICAL THERMOMETERS

House of Representatives bill 7997 introduced b Mr. Kindred on March 17, 1924, and referred to th Committee on Interstate and Foreign Commerc aims to regulate traffic in the clinical thermomete which it defines as "a maximum selfregistering the mometer intended, designed or suitable for use i determining the temperature of the body of man o other animal." The bill provides for the examina tion by the Bureau of Standards of the Departmen of Commerce of all imported clinical thermometer as well as any others intended for interstate shi ment, and provides penalties for the importatio interstate shipment, counterfeiting, or exportatio of such thermometers in violation of the law or th regulations promulgated thereunder.

PARTICIPATION IN PAN AMERICAN SANITARY CONFERENCE

The Senate on March 11, 1924, passed Sena Joint Resolution authorizing the appointment delegates to represent the United States at th seventh Pan American Sanitary Conference, to held at Havana, Cuba, in November, 1924, a appropriated $3,000 therefor. The measure no goes to the House of Representatives for action.

HOSPITAL FUND CAMPAIGN CONTINUES

In spite of the fact that the time set aside for t campaign to raise $500,000 for the Emergency a Casualty Hospitals ended officially on March 2

924, with $281,123.16 raised, voluntary workers vill continue the drive until April 1st in an endeavor o secure the required balance.

WOULD CEDE QUARANTINE SITE

A bill introduced into the House of Representatives by Mr. Kahn of California, on March 6, 1924 (H. R. 7700), authorizes and directs the Secretary f War to transfer to the Treasury Department for uarantine purposes that portion of La Costa Island, Florida, now occupied by the U. S. Public Health Service as a quarantine station under a revocable icense from the War Department.

DEATH OF DOCTOR CROOK

Dr. Harrison Crook, widely known and deeply eloved, was attended to his grave by fellow members of the Medical Society of the District of Columbia, on March 20, 1924. He was a graduate f the Georgetown University Medical School, in ne Class of 1878, and was engaged in active surgical ractice in the Providence and other hospitals of Vashington until 1922, when he retired.

WATER FOR KEY WEST MARINE HOSPITAL

The President, under date of March 18, 1924, ddressed a letter to the President of the Senate Senate Document 72), transmitting supplmental stimates of appropriation for the Treasury Depart- nent for the fiscal year 1924, for providing a water upply at the Key West, Florida, Marine Hospital, 5,500. He concurred in the comments and obser- ations of the Director of the Bureau of the Budget, ho approved the estimate.

REPRESENTATIVE ADDRESSES MEDICAL SOCIETY

Representative John J. Kindred of New York, ho is a physician, addressed the Medical Society f the District of Columbia at its meeting of March 9, 1924, on Eugenics; Its Relation to Mental Dis- ases. Dr. M. L. Bierman spoke on Congenital iaphragmatic Hernia.

ADDITIONS TO CANCER COMMITTEE

Six additions were made on March 20, 1924, to ne Committee of 100, which will direct actively the mpaign against cancer in the District of Columbia pril 7, 1924. The additions include Senator Royal . Copeland, of New York, and William Tyler age, Clerk of the House of Representatives. A refully worked out plan has ensured the coopera- on of practically all of the business and welfare ganizations of the city.

O NEW MEDICAL BUILDING AT HOWARD UNIVERSITY

The Senate has agreed to the conference report n the Interior Department appropriation bill. This easure carried an amendment for $500,000 for the nstruction and equipment of a new medical build- g at Howard University. Unfortunately, the nendment was eliminated in conference.

ORDERS IN THE MEDICAL SERVICES

Medical Corps, U. S. Army Assignments.—Major Charles . Haverkampf to Washington, D. C.; Colonel Henry A. ebber to Atlanta, Georgia; First Lieutenant Edward D. rkes to New York City; Major A. Edward Sherman to rt Sam Houston, Texas; Major John H. Trinder to ot Springs, Arkansas; Colonel Weston P. Chamberlain Panama Canal Zone; Majors John R. McKnight and ouverneur H. Boyer to Walter Reed General Hospital; ajor Wood S. Woolford to Denver, Colorado; Major George B. Foster to Boston, Massachusetts. *Leave,* Major Charles L. Grandy, one month and fifteen days.

Medical Corps, U. S. Navy Assignments.—Commander John L. Neilson, Lieutenant Commanders Henry McDonald and Edward C. White, Lieutenants Frank W. Ryan and Edgar F. McCall, to Marine Corps Base, N. O. B., San Diego, California; Lieutenant Lyman E. Dockery to Receiving Ship, New York, N. Y.; Lieutenant De Witt T. Hunter to Recruiting Barracks, Hampton Roads, Virginia; Lieutenant (J. G.) Albert H. Faber to Naval Radio Station, San Juan, Porto Rico; Lieutenant Arthur D. Hawkins to Naval Hospital, Great Lakes, Illinois.

U. S. Public Health Service.—Surgeon General Hugh S. Cumming took the Oath of Office as Surgeon General of the United States Public Health Service March 10, 1924.

P. A. Surgeon J. W. Mountin, from Jefferson City, Missouri, to Denver, Colorado, and return.

Surgeon J. F. Worley, from New Haven, Connecticut, to Washington, D. C., and return; from New Haven, Connecticut, to Holyoke, Massachusetts, and return.

P. A. Surgeon (R.) D. C. Burkes, from Western State Hospital, Fort Steilacoom, Washington, to U. S. V. H. No. 94, American Lake, Washington.

Surgeon F. M. Faget, from Ellis Island, New York, to Washington, D. C.

P. A. Surgeon J. E. Faris, from St. Thomas, V. I., to San Juan, P. R.

P. A. Surgeon W. T. Harrison, to inspect establishments engaged in the manufacture of biologic products.

Surgeon R. R. Spencer, from Washington, D. C., to Hamilton, Montana, to assume charge of the P. H. S. investigations of Rocky Mountain Spotted Fever.

P. A. Surgeon (R.) G. E. Marchand, from New London, Connecticut, to Washington, D. C.

Surgeon C. L. Williams, from Quarantine, Louisiana, to New Orleans, Louisiana.

Sr. Surgeon E. K. Sprague, from New York City to points in New England States, New York and New Jersey, in connection with his duties as Regional Director of the North Atlantic District.

Surgeon Grover A. Kempf, from Chicago, Illinois, to places in Illinois, in connection with investigations in child hygiene.

Asst. Surgeon (R.) H. T. Floyd, from Baltimore, Maryland, to Oteen, North Carolina.

Asst. Surgeon M. V. Veldee, from Houston, Texas, to Little Rock, Arkansas.

Sr. Surgeon J. C. Perry, from San Francisco, California, to Alpine, California.

Asst. Surgeon O. M. Spencer, from Quarantine, Louisiana, to New Orleans, Louisiana.

Sr. Surgeon J. O. Cobb, from Chelsea, Massachusetts, to New York City for conference.

Surgeon L. P. H. Bahrenburg, from Cleveland, Ohio, to Cincinnati, Ohio.

Surgeon John McMullen, from Louisville, Kentucky, to Cincinnati, Ohio.

Surgeon Carl Ramus, from Evansville, Indiana, to Cincinnati, Ohio.

Surgeon Joseph Bolten, from Chicago, Illinois, to Hot Springs, Arkansas.

Surgeon Taliaferro Clark, from Washington, D. C., to Baltimore, Maryland.

Surgeon L. D. Fricks, from Memphis, Tennessee, to Washington, D. C.

Surgeon W. H. Frost, from Baltimore, Maryland, to Washington, D. C., and return.

Surgeon L. L. Lumsden, from Washington, D. C., to Harrogate and other places in Tennessee.

Surgeon Joseph Goldberger, from Washington, D. C., to New Haven, Connecticut.

Surgeon C. H. Waring, from Hot Springs, Arkansas, to Ellis Island, New York.

Sr. Surgeon (R.) O. B. Mallow, from Chicago, Illinois, to Edward Hines, Jr., Hospital, Maywood, Illinois.

Surgeon (R.) Jefferson B. Latta, from Edward Hines, Jr., Hospital, Maywood, Illinois, to U. S. V. B. No. 92, Jefferson Barracks, Missouri.

Surgeon H. S. Mathewson, from Portland, Maine, to Washington, D. C.

Appointments.—Gregory J. Van Beeck commissioned as Assistant Surgeon, Regular Corps, U. S. P. H. S., effective March 14, 1924. Franklin J. Halpin commissioned as Assistant Surgeon, Regular Corps, effective March 12, 1924.

Book Reviews

THE EMOTIONS

The Emotions. By Carl George Lang and William James. Baltimore: Williams and Wilkins, 1923.

A real contribution is rendered in Volume I of what promises to be a valuable series of monographs edited by Knight Dunlap. This volume contains the original papers which furnished the basis of the James-Lang theory of the emotions. This is the first English translation of Lang's monograph *The Emotions,* which had previously been translated from the Danish into French and German. It is passing strange but none the less true that so well known a work has not been translated from the time of its first appearance (1885). There should be considerable demand for this conveniently arranged monograph. The papers contained are, What Is an Emotion and The Emotions by James, and The Emotions by Lang.

PSYCHOANALYSIS

Papers on Psychoanalysis. By Ernest Jones, M.D. Third Edition. New York: William Wood and Company, 1923.

This is one of the most fundamental works on the subject of psychoanalysis in English. It is more satisfactory than Freud's books which have been translated in America, for Jones sticks closely to Freud, writes lucidly, and avoids the complexities and ambiguities which so frequently mar Freud's translations made in America. In addition, there are many of Jones's original contributions, which have enriched psychoanalytical literature. This, the third, edition contains papers which did not appear in the earlier editions, and which replace others that have been omitted. Anyone interested in psychopathology or in psychoanalysis would do well to read this latest book by Jones.

SURGERY

Operative Surgery. In Three Volumes. By Warren Stone Bickham. With 6,378 Illustrations. Philadelphia: W. B. Saunders Company, 1924. Pp. 900.

There has been for some time a crying need for a system of operative surgery. The first three volumes of Bickham's Surgery have just appeared. This is a tremendous piece of work and it is hard to realize how one author could have so thoroughly covered the scope of general surgery. In Bickham's original one volume work on operative surgery, his anatomical reviews of each surgical condition were excellent. The anatomical description at the beginning of each section in the new edition, with very beautiful and accurate illustrations, can not be praised too highly. In such a comprehensive work as this it is impossible to review completely all the operative procedures.

The author in his introduction wisely states that he does not attempt to cover the entire operative subject, but he attempts to give the standard operative technic for the surgical lesion.

One is glad to see in the first volume a good description of the Carrel-Dakin technic and of the later methods of local anesthesia, including paravetebral and parasacral. The publishers have been most generous in their allowance of numerous photographs. The chapter on artificial limbs is very illuminating and should be studied by every general surgeon.

It is always easy to criticize the omissions in any large work, and in these volumes one notes certain omissions that are to be regretted. For instance, in his description of tendon suture, there is no notice of the Bonnell clamps, which certainly to the general surgeon are a great aid in preserving tendons. The article on bone cavities makes little mention of the recent methods of sterilization of the cavity by Carrel-Dakin and secondary filling of the cavity with fat transplants or pedicle grafts. Also one observes in the section on bone grafts no mention of the osteoperiosteal grafts of Ollier, and DeLangeniére. The reviewer believes that these subjects should be mentioned as they have proved to be valuable additions in their particular lines and have been used long enough to become standardized.

The reviewer feels that if the succeeding volumes are as satisfactory as the three now at hand, this work will be a very necessary adjunct to every surgeon.

POTT'S DISEASE

La Tuberculose Vertebrale—Mal de Pott. By Dr. Lance, Assistant d'Orthopedie a l'Hôpital des Enfants Malades, Paris: Ernest Flammarion. Pp. 246.

This is a most interesting volume, not only to the orthopedist, but to surgeons in general and even to the general practitioner. In the chapter on etiology the author makes some interesting statements, admitting that tuberculosis of the vertebral column can no longer be considered hereditary, but that it is always an acquired affection and that its origin may be the tubercle bacillus of the bovine or human type. He states that in the bovine race in France from fifteen to twenty per cent. and in certain other countries as high as fifty per cent. are afflicted with tuberculosis. The author sees no danger from the ingestion of meat from tuberculous cattle but great danger from the ingestion of milk from tuberculous cows.

The frequency of Pott's disease as compared with disease in other bony regions of the body, he ascribes to the spongelike structure of the vertebræ. The various deformities resulting from the tuberculous lesions of the vertebræ are well described and illustrated by numerous cuts and photographs. With the aid of a great many x ray pictures the gradual process of destruction in the cervical, dorsal and lumbar regions is shown clearly. In the chapter on diagnosis the author emphasizes the importance of early recognition of the disease and justly calls attention to one of the earliest symptoms, namely, rigidity of the vertebral column. Under differential diagnosis he mentions osteomyelitis, the hysteric and the syphilitic types of Pott's disease, and congenital malformations. He very wisely says that no positive diagnosis should be made without an x ray picture.

Under treatment nothing new is offered. In the chapter on surgical treatment it is gratifying to see that credit is given to the works of our own Hibbs and Albee. A special chapter deals with Pott's disease in infants and Sayer's interesting illustrations showing how the diagnosis should be made, are

reproduced. The method of determining the flexibility of the vertebral column is given.

The remaining chapters deal with Pott's disease in the adult and the aged. Considering the treatment of the former the author deplores the lack of hospitals at the seashore for such cases among the poorer classes, for the lengthy and costly sojourn in a private institution is making a successful treatment for the masses virtually impossible. In the chapter on Pott's disease among the aged, several different types are described. In the classic form, due to the formation of an abscess, the diagnosis is often difficult, because there may be no pain and on account of the age of the patient one seldom thinks of Pott's disease. Secondly, there is the nervous type with its numerous symptoms, pseudoneurology, paraplegia, etc.; thirdly, the rheumatic type, and fourthly, the pulmonary type. Lastly, the author describes Pott's disease in the pregnant woman and makes the statement that repeated confinements and breast feeding of the infant may dispose to tuberculosis of the vertebræ, but he admits the rarity of this as an etiological factor. As to allowing a woman with an old latent Pott's disease to marry and bear children, he thinks that permission can be granted providing there are no cardiac or respiratory complications. On a whole, the book is an excellent and concise exposition of what is known today of the etiology, diversity of types, and treatment of Pott's disease.

MENTAL EVOLUTION

Man's Mental Evolution, Past and Future. By Harry Campbell, M.D., F.R.C.P. London: Baillière, Tindall and Cox, 1924.

In this small volume the author has attempted the ambitious task of discovering the factors which have determined man's mental evolution. Having stated what he believes these factors to be, he discusses the question of how far they are still in operation and he endeavors to forecast man's future destiny. This appears to be the first serious attempt to deal with these fascinating problems.

Campbell contends that mental evolution has to be studied on the same lines as morphological evolution, and that the problems for solution are just as susceptible of solution in the one case as in the other. He falls foul of those biologists who belittle the influence of selection in biological evolution, insisting that without selection organic evolution would be impossible. He repudiates Bergson's assumption that the evolution of species takes places in response to an *élan vital*, arguing that, just as in the evolution of the bicycle, only a few of the many inventions, natural variations, have survived the selective scrutiny of the public, so for every organic variation which has survival value, many are eliminated as harmful, and that organisms have thus at least as great an innate tendency to retrogress as to evolve. The argument appears incontrovertible.

The author lays down the maxim that mental evolution takes place by the natural selection of individuals possessing enhanced mental endowment, but only when this confers survival value. He is, however, careful to point out that enhanced mental endowment does not possess survival value except under certain conditions. These conditions are that the individual possessing it shall be anatomically equipped with the means of giving effect to the added endowment, and that the environment shall afford the necessary scope, or opportunity, for the extra intelligence.

These propositions he illustrates by reference to the fish, the bird, the monkey, the large ape, and man. Heightened intelligence would not benefit the fish, both because the creature lacks the anatomical equipment, in the shape of prehensile digits, necessary to give it effect, and also because the watery medium in which it lives affords no scope for the exercise of superior intelligence. The bird, with superior anatomical equipment and wider scope, has reached a higher mental level, but both these favoring conditions are restricted and thus the survival value is kept to a definite low level. The tailed monkey has attained to a comparatively high level of intelligence, owing to the high survival value which the possession of hands has put upon intelligence. On the other hand, its essential arboreal life affords but limited scope for the exercise of this enhanced intelligence, the survival value of which has been permitted to advance beyond the simian level. In the case of the large anthropoids, the scope for intelligence has been greatly widened by a semiterrestrial life which, however, has limited the survival value of intelligence to the anthropoid level. On the other hand, when the prehuman anthropoid ape abandoned the forest and became a purely terrestrial animal, he was afforded a maximum scope for the exercise of intelligence. Superior intelligence then came to possess a survival value such as it had never possessed before, and this led to the evolution of man such as we know him today.

The author believs that directly man's anthropoid ancestor left the forest, he became a hunter, seeing that the gorilla is now known to hunt small game. He contends that the career of hunting vastly increased the survival value of intelligence, that the prehuman anthropoid, lacking the equipment for slaughter, anatomical and instinctive, of the tiger, he was compelled to rely upon his wits in hunting his prey. For which instinct, he had to substitute strategy; for natural weapons, weapons made by hand. When the tribal stage was reached, polygamy further favored mental evolution. "The chief of a tribe needs courage, promptitude, tact, a nimble intelligence, a quick apprehension. We may be sure that the consistently wise man, the man who uniformly proves himself to be in the right, the clear-seeing, farseeing, resolute brave man, ever ready to take the initiative and to share the common danger, will come to be looked up to, feared, obeyed, in short, to be recognized as a leader. If to these qualities he adds a sense of justice, he will not only be feared but respected, possibly loved. This is the type of man who rises to leadership, kingship; who leads his tribe to victory and extends his dominion and power. It surely cannot be doubted that among normal tribal people such a man tends to leave more than the average number of offspring."

The author advances intertribal law as a third factor in favoring man's mental evolution. Modern warfare is dysgenic, in that it eliminates the physically fittest and bravest, those least careful of their skins. It has also to be observed that the total effect

on the population is much the same for the victor and the vanquished. In intertribal warfare, on the other hand, all or practically all the men of the tribe take part in the fight, but the percentage loss of the vanquished is generally much greater than that of the conquerors. Defeat may mean practical annihilation of the vanquished, and the ceaseless destruction of inferior by superior tribes has favored mental evolution.

As regards racial differences of intelligence, the author points out that we are apt to take our standard of European intelligence from the classes rather than from the masses. "The comparatively high intelligence of the upper classes in Western Europe leads to a selective mating of the most intelligent, thus intermarriage of the most intelligent members of the community is more favorable to the production of exceptionally gifted offspring than unions among primitive people where no such selective influence is at work. The intermarriage of the most intelligent among civilized communities must, one would think, increase the number of exceptionally gifted among them." May it not be "that the average redskin or the negro is as intelligent as our own unskilled workers and more intelligent than our unemployable"?

Campbell applies the same principle of survival value to the evolution of the instincts and the feelings. "As to the mode of evolution of those feelings, dispositions which are adaptive, which constitute the basis of adaptive instincts, there can be no doubt that they have evolved on the same lines as intelligence, that is, by virtue of their survival value, and moreover, that such survival value has implied the evolution of the appropriate anatomical component needful to give effect to their promptings. All the combination of feeling dispositions pertaining to the adaptive instincts of subhuman animals, and the corresponding feeling dispositions in ourselves have arisen by the selection of feeling disposition possessing survival. It is unconceivable that they can have come into being as the result of a prophetically endowed *élan vital,* acting independently of selection." The supposition, e. g., that the slaughtering instinct of the tiger has evolved in response to an *élan vital,* an innate 'urge,' implies prophetic vision, the ability to look into, and make provision for, an unknown future. Does it follow, asks the author, that because man has advanced mentally in the past, he will continue to advance in the future, that a veritable superman will emerge? It is, he maintains, just a question of the survival value of superior mental endowment, intellectual or moral. Intellectual superiority, no longer having any survival value, the least intelligent section of the community being the most prolific, has for the time being at least come to a standstill. If, however, superior intelligence continued to possess survival value for a sufficiently long period, a race of supermen would evolve. While the intellectual future of man gives little promise of advance, the author is more hopeful of man's moral future. The monograph ends with the notable pronouncement, "I have sought to lift the problem of man's mental evolution out of the region of vague surmise, and to show that it comes well within the province of science, and that it can be reduced to simple terms. There is, it seems to me, but one problem which transcends it in interest, that stupendous problem whether our brief career here is the beginning or end of us, or whether we are to live forever under other conditions. There we seem to pass beyond the realm of the knowable and to stand at the gate of the unknown and the unknowable."

Dr. Campbell has compressed into somewhat over seventy pages of printed matter, a most thoughtful consideration of one of the most fascinating problems of life, a problem it may be said, that Darwin himself did not attempt to solve. No one is better equipped than the author for placing the subject before the reader in clear terms and with complete knowledge, as it is a subject he has almost made his own. As said before, it is the first serious attempt to grapple with the question of man's mental evolution and to endeavor to lift the veil which covers or obscures man's future destiny. The arguments brought forward carry great weight, as the deductions formulated are founded upon a sound basis and the explanations are satisfactory. The book gives one to think and is written in a highly attractive philosophically scientific manner. In fact it is eminently readable, unlike many scientific works of less real value. It is to be hoped that this review and the exposition given of the author's salient points may lead to the wide reading of a book which will well repay a close study.

DIAGNOSTIC TECHNIC

Diagnostische Technik für die ärztliche Praxis. Ein Handbuch für Arzte und Studierende. By various authors. Herausgegeben von Professor Dr. Julius Schwalbe, Geh. San.-Rat. Mit 380 Abbildungen. Leipzig: Verlag von Georg Thieme, 1923. Pp. xv-851.

This work on diagnostic technic, written under the collaboration of a number of the greatest specialists in their respective fields and the editorship of Schwalbe, is a companion book to the similarly planned book on therapeutic technic also edited by Schwalbe. It is unique in that it covers the entire field of medicine and it appeals especially to the general practitioner and the medical student, as well as to specialists and workers on scientific problems in hospitals. The diagnostic problems of the general practitioner are given special attention but other features, with which he should be acquainted but which are too elaborate and technical for routine practice, are also discussed and described. Wherever the diagnosis and differential diagnosis are important the necessary technic of the required tests is also given. An up to date bibliography is appended to each chapter. The first portion of the book deals with the general technic of examination of the patient and the various procedures used, such as physical examination, röntgenography, microscopy and bacteriological and immunological examinations. The special portion of the book is concerned with hematology, endocrinology, the examination of the respiratory, circulatory and digestive systems, metabolic studies, the study of the kidney, male sexual functions, the nervous system, surgery, gynecology obstetrics, ophthalmology, otology, the upper respiratory tract, the teeth, dermatology, venereal diseases, acute infectious diseases, chronic tuberculosis, intoxications, and the examination of children. This work may very satisfactorily be used as an aid in diagnostic technic.

Medicoliterary Notes.

A bibliography on social and industrial psychology has recently been compiled and published by the Russell Sage Foundation.

* * *

In his book entitled The Minds and Manners of Wild Animals, Dr. William T. Hornaday, director of the New York Zoological Park, tabulates the relative intelligence of wild animals as he has observed it. The chimpanzee scores 925, the lion 725, the tiger 575. A lion raised in captivity is the most good natured and amenable of all the beasts.

The teachers of physical education of Mexico have formed an alliance for better education and for the general development of sports in the republic.—*Nation's Health.*

* * *

Incompatibility in Prescriptions and How to Avoid It is the title of a pamphlet by Thomas Stephenson, D.Sc., editor of the *Prescriber* (Edinburgh). He quotes a definition of incompatibility as "any intentional change which notably interferes with the elegance, usefulness, or safety of the prescription"; and divides his discussion of such changes into the chemical, physical or pharmaceutical, and therapeutic phases.

* * *

A recent report of the New York City Sanitary Bureau for 1922 gives some interesting data. One would not suppose it possible that among dead animals removed from the streets could be three elephants, two camels, three seals, and one alligator, one bear, one lion and one deer. The total of dead animals removed was 307,603. Dog bites to the number of 4,538 were reported and 165 cat bites. Another section of the report states that samples of air were collected from subway cars during July and August for estimating carbon dioxide content. No report is made of what was found.

National Safety News for October, 1923, contains a full and valuable list with description and other information of approved safety devices for that year.

* * *

Pneumonia and its prevention is the subject of the *Illinois Health News* for January. This issue of the bulletin makes a very practical little guide for popular use.

* * *

Even New Zealand, which now has the longest life span of the world, has its health problems. A recent report states that ordinary inspection of school children has revealed that ninety per cent. of them have carious teeth. Thorough examination would probably have shown a much larger proportion. The ratio of schools near sweet shops to those remote was 100 to 73.5.

* * *

In 1923 the Pennsylvania State Department of Health inaugurated a campaign for the immunization of children against diphtheria. This resulted up to June 1st in administering toxin antitoxin to 42,519 children.

* * *

Crazy Man, the title of a recent novel by Maxwell Bodenheim, is reputed to tell the story of an actual person who lived in New York City a few years ago, who won the interest and respect of many, and who is now in an institution for the mentally diseased. The book tells the story of a reformed thief who tries to impress upon the world his fantastic visions, sometimes with truth underlying them, and of a girl who is a professional hostess at a dance hall of rather ill repute.

* * *

A recent issue of the *New Republic* reprints from Julian Huxley's *Essays of a Biologist*, published by Knopf, a discussion of sexual sublimation from the biologist's point of view. Psychoanalysis and its results are considered and criticized as of doubtful value as a part of education in sex matters. "Analysis," writes Huxley, "constitutes a serious surgical operation for the mind . . . and we do not want to perform this operation on healthy people any more than we want to open their abdomen to see that their viscera are normal."

* * *

A French government report gives the estimated number of cripples resulting from the World War as more than ten million. The country with the largest number is Germany, with 1,537,000. The number in the United States is given as 157,000. France ranks second with 1,500,000, and Great Britain third with 1,170,000.

* * *

Salaries and tenure of office of city health officers is the subject of an enlightening study by State Commissioner of Health Matthias Nicoll, Jr., of New York in the *Nation's Health* for January. Commissioner Nicoll shows that the smallness of the usual salary of such officials means that they cannot long make so great a financial sacrifice, with the result that nearly one third have held office for one year only, and more than one half for five years or less. This is a labor turnover that costs both money and efficiency.

* * *

The first annual Safety Night for professional auto drivers was held recently at one of the New York theatres under the auspices of the Bureau of Public Safety of the Police Department. There were addresses on various phases of the subject of safety by prominent men and an all star vaudeville bill.

The *National Health Series* is a set of twenty volumes on various health topics and problems published by Funk & Wagnalls under the editorship of the National Health Council, with headquarters in New York City.

* * *

Professor Bourget of the Paris Academy of Medicine is reported to have addressed that august body lately on the subject of the relation of personal ugliness or disfigurement to neurasthenia and other mental disorders. He emphasized the great importance from the medical point of view of socalled beauty surgery and presented some remarkable cases to illustrate his opinions.

* * *

The *Living Age* tells us that in Turkey, contrary to common belief, it has become too expensive to maintain a harem, so a ban on polygamy has recently been pronounced in Angora. A town in Anatolia has gone further and limited the expense of the marriage ceremony. There must be no music except a drummer, and he must obtain a legal permit; only three vehicles may be sent to transport the bride, and the fees for these are strictly fixed; tips are forbidden, the bride cannot be adorned with gold coins, carriages must not be decorated, and the bride must not be given more than two suits of clothes and one set of furniture, and wedding presents from relatives are taboo.

* * *

The *Nation's Health* for January has an article of unusual interest on the public school clinics of North Carolina. Probably the most important are the dental clinics because much of the population of that region have notably poor and defective teeth, the result of long neglect through ignorance of care.

* * *

The U. S. Department of Commerce has announced that 1,101,863 deaths occurred in 1922 within the death registration area of continental United States. This represents a death rate of 11.8 per 1,000 population as compared with 11.6 in 1921. The slight increase in the rate is attributed to the increase in the rate for influenza and pneumonia from 99.8 per 1,000,000 population in 1921 to 133.5 in 1922. Some of the other diseases for which the rates increased were cancer, diabetes, diseases of the heart, nephritis, cerebral hemorrhage, automobile accidents, falls and burns. A marked decrease appeared for diarrhea and enteritis, under two years of age, all forms of tuberculosis, typhoid fever, puerperal septicemia, whooping cough, scarlet fever, drowning and suicides.

Organized play, theory and practice, is the subject of a work in two volumes by Wilbur P. Bowen and Elmer D. Mitchell, published by Barnes, New York. Volume I deals with the history of the play conception, and the psychology and philosophy of play; Volume II is purely practical, containing lists and directions for games.

Abstracts from Current Literature

RADIOLOGY

Light in the Treatment of Cutaneous Tuberculosis.—J. H. Sequeira (*British Medical Journal,* September 22, 1923) draws the following conclusions: 1. We must carefully distinguish between the local application of concentrated light to lesions and the light bath. 2. The best results in the treatment of lupus vulgaris are obtained by a combination of local and general treatment. The former requires the application of concentrated actinic light to the lesions. The light bath is the exposure of the nude body and limbs to the rays of a large arc lamp. 3. The best illuminant is a large carbon arc working at fifty amperes, which is not enclosed as an envelope cuts out some portions of the rays. 4. The amount of pigmentation is an index of the reaction to the radiation, and nothing more. 5. As a general rule the greater the pigmentation the better the results. 6. Ninety per cent of all cases can be cured by a combination of the light bath with local phototherapy. The efficacy of local treatment is intensified by the application of light to the whole surface. 7. In addition to the healing of tuberculous skin lesions, sinuses, etc., the patients increase in weight, their general health improves to a remarkable degree and their mentality is most favorably influenced. 8. It appears likely that in certain subjects the treatment may require repetition at intervals. 9. Apart from tuberculosis the light bath can be recommended as a general tonic.

Thorium X in the Treatment of Myeloid Leukemia.—C. Aubertin (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris,* January 17, 1924) had noticed that in cases of chronic rheumatism treated with thorium X a marked fall in the leucocyte count, to a minimum of 1500, took place, with polymorphonuclear leucocytosis and eosinophilia. He reports a case of myeloid leucemia in which seven weekly subcutaneous injections of from two hundred to four hundred micrograms of thorium X were given, with the result that the leucocytes dropped from 22,500 to 2,700. The erythrocytes meanwhile also dropped from 2,850,000 to 1,890,000. Three x ray treatments were given later. After cessation of treatment the leucocytes continued to fall, down to 1,500, which figure still obtained five months after the last injection of thorium X. The percentage of neutrophile myelocytes was then 5.5 per cent., against 29.75 per cent. before treatment. The spleen began to subside only after a long interval after cessation of treatment, then became much reduced in size. Ten months after the beginning of treatment the leucocytes were still at 3,300, while the erythrocytes had returned to their original level. Like doses of thorium X had been given in rheumatic cases without causing any special anemia; apparently the erythrocytes in leucemics are more vulnerable to thorium X than in subjects with normal blood. The thorium X treatment of leucemia is a simple one; although the preparation deteriorates, a physician in an out of the way place could easily receive it regularly by mail. The treatment seems easier to manage than benzol treatment.

Advantages of the "Loading Slot" in Radium Emanation Implantation.—Joseph Muir (*Journal of Urology,* March, 1924) says that the implantation of radium emanation seeds in connection with cystoscopy, and otherwise, has been practised for a period of about ten years. The technic employed is stated briefly as follows:

First, the fixing of the seed in the point of the needle with vaseline; second, the introduction of the needle itself through the cystoscope; third, the implantation of the seed by means of the plunger.

Using the method outlined above, a considerable amount of time is consumed, as the implanter had to be completely withdrawn for each implantation. Because of this, visual observation was continually interrupted, and consequently the location of successive implantations was not only a matter of uncertainty, but the implantation of successive seeds in the same puncture channel was practically an impossibility; in other words, the exact distribution of seeds, and the size of the dose was a matter of guesswork.

All these shortcomings may be obviated by the use of the author's flexible radium seed implanter, with the loading slot. Using this instrument, a large number of seeds may be implanted in a much shorter space of time, with less traumatism, and with few portals of entrance. The field of implantation may be mapped out with accuracy under constant visual observation, and successive seeds can be imbedded in the same puncture channel, to any depth, and at any interval with mathematical accuracy. Therefore, it is obvious that the flexible radium seed implanter provides the highly desirable factor of uniform distribution of radium emanation seeds, i. e., radiation, and in addition avoids the former necessity of surface radiation. This latter supplemental radiation formerly had to be resorted to because of the possibility of imperfect distribution.

The Influence of Radiant Energy upon the Development of Xerophthalmia in Rats.—G. F. Powers, E. A. Park, and Nina Simmonds (*Journal of Biological Chemistry,* April, 1923) presented a remarkable demonstration of the beneficial influence of sunlight and out of door air upon the organism. They fed rats on diets which under ordinary conditions of room light would bring about the development of both rickets and xerophthalmia, and of xerophthalmia alone. Animals so treated, when exposed to the quartz mercury vapor lamp for thirty to sixty minutes, though they were not prevented from the development of xerophthalmia, were improved in bodily vigor to a very limited degree. In rats exposed to direct sunlight, xerophthalmia did not develop, with one exception, until the rats in the other groups had contracted the disease and died. None of these rats had rickets. These experiments emphasize that sunlight with such factors as may be closely linked with it, has wonderful power to promote health, bodily vigor, and longevity in animals otherwise unable to adapt themselves to markedly adverse environmental conditions.

Artificial Light Treatment of Lupus and Other Forms of Tuberculosis.—Axel Reyn (*British Medical Journal,* September 22, 1923) summarizes his conclusions as follows: 1. The nonoperative treatment is the principal one in cases of surgical tuberculosis, not only in children but also in adults. 2. Light baths (sun or artificial) are indispensable in the nonoperative treatment of surgical tuberculosis. 3. The carbon arc light can fully replace sunlight, and is much superior to the mercury arc light. 4. Sanatoria in mountain heights, as well as at the seaside, should have artificial light baths at their disposal. 5. In the treatment of lupus vulgaris concentrated chemical light is absolutely indispensable, and it is of the greatest value to combine local treatment with light baths.

Silhouette Radiogram.—A. P. Bertwistle (*Lancet,* October 6, 1923) prepares röntgenographic silhouettes by scratching the negative with a pin, following carefully the skin outline. From this a print is made and the background is blocked out with India ink. The negatives usually show a clear outline. This procedure results in röntgenographic silhouette, which has the properties of a röntgen plate and a clean cut silhouette, which brings out clearly the deformity or otherwise of the soft parts. The advantages claimed for this procedure are the following: 1, a more striking clinical picture, often rendering a photograph unnecessary; 2, the ease with which it may be obtained; 3, the position in which the limb is photographed is indicated and 4, the cause of the whole deformity may be analyzed at a glance.

Effect of X Rays of Different Wave Lengths upon Some Animal Tissues. Proof of Differential Action.—S. Russ (*Lancet,* September 29, 1923), by means of experiments, in which a comparison was made of the amounts of energy liberated in the tissues by hard and soft rays, showed that when equal amounts of x ray energy are absorbed from beams of different wave lengths by animal tissues, the reactions of these tissues may differ considerably in degree and possibly to some extent in nature. The experiments show that a bigger differential effect between hard and soft x rays exists for the skin of the rat than for the tumor cells. Provided this also holds for the human subject it is one argument for the use of very hard x rays or gamma rays when tumors at a considerable depth below the skin have to be irradiated. The conclusion would perhaps be just the reverse in superficial conditions not involving the irradiation of normal skin. The result also raises the question whether the specification which has been adopted

by Seitz and Wintz for expressing the carcinoma dose in terms of the skin dose is sufficiently rigorous, for this may be a function of the wave length. The two main results obtained are that about six times as much short wave length energy as long wave length energy must be expended in a layer of skin in order to produce equal reactions and that this factor falls to about 2.6 in the case of the tumor.

Diagnostic Findings in Pyelography and Pneumoradiography.—A. Ritter and R. Allemann (*Schweizerische medizinische Wochenschrift,* October 4 and 11, 1923) applied the Rosenstein procedure of pneumoradiography of the kidney bed at times in addition to pyelography in thirty cases in which the differential diagnosis was difficult. In a series of cases of nephroptosis, malformation and dystopia, tumors, tuberculosis of the kidney and hydronephrosis, in which the clinical diagnosis was uncertain, it was readily made after the use of these procedures. The latter were useful in the differential diagnosis of tumor and constriction of the liver, tumors and hydrops of the gallbladder, tumors of the stomach and intestine, and of the mesentery, torsion of the pedicle of an ovarian tumor, etc., and in the differential diagnosis of renal affections themselves, such as hydronephrosis, pyonephrosis, tumor, solitary cyst, and tuberculosis. This technic is superior to pneumoperitoneum, especially in marked formations of adhesions in the abdominal cavity. Air and carbonic acid gas embolism did not occur. The contraindications include large and infected hydronephroses, paranephritic abscesses, extensive cavernous phthisis and neuroses.

Röntgen Ray Treatment of Eczema.—William J. Macdonald (*Boston Medical and Surgical Journal,* December 6, 1923) says that acute eczema will clear up on suitable local treatment, diet and rest, but it is best to supplement this with the x ray, which offers a rapid, clean, and tolerably certain cure in most cases. The diet must always be corrected, excess of carbohydrates and eczema are mutually related.

Phototherapy of Migraine.—Leopold Freund (*Wiener klinische Wochenschrift,* October 18, 1923) obtained such excellent results with phototherapy in migraine that he believes its use to be justified. He believes in the use of long wave rays of light. Naturally, this form of treatment is indicated only in the spastic form of hemicrania, but not in the angioparalytic form nor in those patients who cannot bear the action of the light during the attacks.

OPHTHALMOLOGY

Glaucoma.—G. P. Hawker (*Lancet,* October 13, 1923) states that there is no disease more difficult to diagnose than chronic glaucoma, and only by weighing all the signs can a decision be made between it and early optic atrophy and retrobulbar neuritis. The field of vision in early glaucoma shows contraction of the nasal side, while in optic atrophy it is concentric. The tension should be taken if possible with a tonometer. In shallow glaucomatous cups the disc is pinkish, while in optic atrophy it is pale. There is, however, always some atrophy of the nerve with a cupped disc, and between this atrophy and simply atrophy with a slight depression there is much scope for error in diagnosis. The author has seen a fairly advanced case of glaucoma without any visible change in the disc. Chronic glaucoma is almost as common a cause of loss of sight as cataract and if this fact is borne in mind many cases can be treated while there is yet time. Acute glaucoma is comparatively rare.

Oxycephaly in Eye Disturbances.—A. Léri (*Presse médicale,* January 19, 1924) asserts that the ocular disturbances in oxycephaly appear to be due to at least three causes: 1, collapse of the floor of the middle fossa at the base of the skull, with disappearance of the sphenoidal sinus and tilting of the sphenoid bone, making pressure at the bottom of the orbit and thus causing protrusion of the eyeballs and sometimes compression of the optic and oculomotor nerves. 2. Intracranial hypertension, proved to exist by x ray evidences, such as disappearance of various bone sinuses, "digital" impressions in the frontal and parietal regions and impressions of the large venous sinuses in the cranial bones, as well as clinically by increased pressure of the cerebrospinal fluid and disappearance of brain tumors in certain cases. 3. Cranial deformity, apparently the result of premature synostosis of the coronal and sagittal sutures, the latter ascribed, in turn, either to a basal meningitis or to rachitic osteitis. The evidences of meningitis or rickets do not explain all the cases. On the other hand, adenoid growths, and in a general way, the nasopharyngeal infections which are common in infancy, seem to be one of the essential causes of the disorder. In the newborn child the nasopharynx communicates extensively and directly with the middle section of the base of the skull. These infections are thus capable of causing by direct extension either the basal meningitis or osteitis which lead to the premature synostosis and which have hitherto been erroneously considered as primary. There is thus produced a selective collapse of the middle section of the base of the skull which contrary to prevailing opinion, is not due to intracranial hypertension, for such a collapse does not occur in any other variety of intracranial hypertension, including brain tumors, hydrocephalus, and Paget's disease. There occur, furthermore, cases of optic neuritis similarly caused and featured radiographically by exclusive collapse of the middle section of the base of the skull without any of the other osseous deformities of oxycephaly. The meningitis and osteitis following nasopharyngeal infections add a third inflammatory cause to the two mechanical causes, viz., collapse of the base and intracranial hypertension, which induce the ocular disturbances of oxycephaly. The knowledge of these causes leads to certain definite therapeutic indications: Decompression or callosal puncture to combat the hypertension, and disinfection and curettage of nasopharynx and adenoid vegetations. The excellent results obtained through operation on the adenoids, even at a late stage, by Gradenigo show how much may be expected from these procedures.

Purtschner's Indirect Injury of the Retina.—A. Vogt (*Schweizerische medizinische Wochenschrift,* October 11, 1923) states that Purtschner's injury of the eye, associated with retinal hemorrhages and typical white, cloudy superficial foci, is due to a fall or a blow on the head as a result of an acute increase in blood pressure within the skull. There is no sign of a direct injury to the bulb of the eye. The author describes two cases and discusses the differential diagnosis of retinal hemorrhages from compression of the body and of the Berlin cloudiness of the retina due to contusion, the picture of which is entirely different. The cloudiness is not superficial and does not cover the blood vessels as in Purtschner's indirect injury and it disappears after several hours.

Curability of Trachoma by Injections of Copper Sulphate.—W. Nicati (*Bulletin de l'Académie de médecine,* January 8, 1924) states that sterilization of conjunctival trachoma is feasible by injections of copper sulphate, which should rank as a specific in this condition to the same extent as mercury or arsenic in syphilis. Solutions of 0.1 to 1 per cent. strength are used—the former put up in ampoules of two mils and the latter in ampoules of one mil, with stovaine added for local anesthetic purposes. The injections are made into the conjunctival cul de sac immediately behind the tarsus, and are repeated until recovery is obtained, every eight, ten or fifteen days. Each successive injection is given shortly after the disappearance of the intense edema produced by the preceding injection. The maximum number of injections in each eye was six. Recovery is marked by a *cicatrix pallida* or pale, smooth, flat scar, without ulceration nor contraction. The injection treatment in no wise excludes the customary treatment by applications and instillations.

Complications Following 1322 Consecutive Cases of Cataract Extraction.—M. M. Cruikshank (*Indian Medical Gazette,* October, 1923), a member of the staff of Dr. Holland at Shikarpur, says that though a strong advocate of the intracapsular method, Holland is convinced that it is not necessarily the operation of choice in every case. To the three classes, juvenile, congenital and secondary cataracts, which Smith considers as unsuitable for the intracapsular operation, Holland adds five more, as follows:

1. The socalled oxeye type—the very prominent eye found in full blooded plethoric individuals, in whom vitreous prolapse is apt to occur. It is difficult to ascribe a reason for the prolapse in these cases. Routine use of the tonometer, however, might throw some light on this point.
2. Those cases of double cataract in black haired, healthy men of from thirty-five to fifty years of age, in whom the zonular fibres are still very resistant and require a pressure for their rupture which leads to vitreous loss.
3. Those cases of cataract in glaucoma and of glaucomatous cataract, in which a preliminary iridectomy is advised; the lens being extracted with capsulotomy three weeks to twelve months later, to avoid if possible the danger

of choroidal hemorrhage. In these cases Holland stresses the point that the incision must be made slowly, the aqueous being allowed to escape slowly and to balloon out the conjunctiva.

4. Cases of traumatic cataract. In these cases prolapse of vitreous is very likely to occur, probably owing to the fact that the trauma has already ruptured the hyaloid membrane and the pressure exerted in extraction in the capsule is therefore more liable to cause vitreous loss.

5. Those cases in which ordinary, legitimate pressure fails to dislocate the lens. It is very difficult to persuade oneself that the lens which is just refusing to present belongs to this class, and the inexperienced operator is tempted to try that little more pressure which ends in escape of vitreous before the lens presents.

GYNECOLOGY AND OBSTETRICS.

Febrile Abortion.—G. Winter (*Zentralblatt für Gynäkologie*, September 22, 1923) sums up the twelve year old discussion on the treatment of febrile abortion as follows: 1. Whoever cannot or will not make bacteriological examinations of the secretions should not attempt evacution of the uterus in the febrile stage, but only after about four to five days following the defervescence; the defervescence should not be waited for longer than five days. 2. The spontaneous expulsion should be aided in every case by quinine. 3. Hemorrhages are no indication for a hasty evacution. 5. Complicated abortions should not be subjected to evacution. 6. The dull curette seems to possess advantages over the manual evacution.

Sex Papillæ in the Female.—B. Lipschütz (*Wiener klinische Wochenschrift*, September 27, 1923) describes a symmetrical zone of papillæ situated on the inner surfaces of the labia minora, which consist of embryonal connective tissue with thickened or narrowed epithelial coverings and contain abundant terminal corpuscles resembling the fungiform papillæ of the tongue. Their development during the period of puberty and their retrogression during the period of senility seem to point to the fact that these papillæ have an important function in libido, which is not due to the sensory apparatus of the clitoris alone.

Experiments with the Tubal Inflator.—Hugo Sellheim (*Zentralblatt für Gynäkologie*, September 15, 1923) reports some additional efforts at inflating the fallopian tubes with his apparatus for the purpose of testing the patency of the tubes. The air is forced through the tubes under normal conditions at a pressure of fifty to one hundred millimetres, and at the most at a pressure of two hundred to two hundred and fifty millimetres; at a pressure of three hundred millimetres the tube is likely to rupture. This procedure is applicable not only for diagnostic purposes but also for therapeutic purposes, inasmuch as the pressure is able to set aside slight obstructions. However, in the presence of infection in the uterine cavity, this procedure may lead to difficulties.

Use, Effect and Dangers of Hypophysis Medication in Obstetrics.—J. Mennet (*Schweizerische medizinische Wochenschrift*, June 7, 1923) states that hypophysis medication, both when used in the usual manner and intravenously, gives excellent results in obstetrics. Nevertheless, it should be borne in mind that this treatment is subject to a great number of dangers, which should be well understood in order to avoid severe mishaps. The injection of pituitrin and pituglandol, without indication, cannot be too severely condemned, as it injures the reputation of actually good preparations. The injection of extract of hypophysis by a midwife without distinct supervision of a physician must be opposed most energetically.

Middle Course in the Treatment of Eclampsia.—Paul Zweifel (*Schweizerische medizinische Wochenschrift*, September 29, 1923) shows that the middle course of treatment in eclampsia, as conceived by Engelmann, has caused considerable confusion. Some feel justified in doing an occasional Cæsarean section, while others believe in inducing a premature delivery in pregnancy in the absence of labor pains. The author found that the blood in eclampsia shows an abnormally excessive specific gravity and that venesection is not followed by any mortality. The withdrawal of blood in amounts of 1400 to 1800 c.c. was borne without any harmful results. Narcotics may be given but no morphine should be given if the child is living. As soon as the spontaneous delivery is in progress delivery is begun, but Cæsarean section is contraindicated.

Applicability of the Meinicke Flocculation Reaction with Cholesterinized and Cholesterin Free Extract in Obstetrics.—H. Thaler and E. Klaften (*Zentralblatt für Gynäkologie*, October 6, 1923) maintain that the most recent clouding reaction of Meinicke with cholesterin free extracts may well be recommended as an exceedingly simple complementary reaction to the Wassermann reaction as a control of syphilis. The cholesterin free extract of very weak dilution (eight fold) was found to be particularly useful in the study of obstetrical material. The simultaneous application of the Wassermann reaction and the Meinicke clouding reaction afford a more reliable conclusion in pregnancy, in labor and in the puerperium, both in the evaluation of the serological findings in syphilitic women and in that of the nonspecific cases. At the present time the following recommendations are made in regard to the technic: Active serum, a two per cent. sodium chloride solution for the dilution of the extract and room temperature; it is also necessary previously to heat the utensils and reagents, as well as to make accurate readings, which are to be considered as clouding after one and after four hours and as flocculation after twenty-four hours.

Acetonuria in Pregnancy. — Pritzi and Lichtmann (*Wiener klinische Wochenschrift*, August 23, 1923) observed the acetone test to be positive in forty-four cases of pregnancy; in seven control cases it was positive only once. The authors come to the conclusion that the tendency to acetonuria, provided the pregnant woman is carefully watched, may be successfully utilized in the diagnosis of pregnancy. A positive reaction certainly points to pregnancy; a negative reaction does not definitely exclude pregnancy, but makes it unlikely. However, the conclusion should not be drawn that this test is applicable in the diagnosis of indefinite gynecological cases, especially in febrile conditions and where there is a reduced state of nutrition. Additional investigation should be made to determine whether or not this test is applicable in the differential diagnosis between adnexal tumors and ectopic pregnancy.

Prognosis of Cardiac Disease in Pregnancy.—Walter Frey (*Zentralblatt für Gynäkologie*, October 6, 1923) believes that pregnancy does not as a rule aggravate cardiac disease during pregnancy any more than any other intercurrent diseases. The prognosis of heart disease is therefore not particularly bad. Mitral stenosis does not take up any unusual position in this respect, and it is compensated for a long time just as well as mitral insufficiency. Cardiac sufficiency is dependent in the first place, not upon the location of the valvular lesion, but upon the condition of the musculature. Just like other cardiacs, pregnant women afflicted with cardiac disease die only exceptionally from mechanical factors, but always from a freshly occurring inflammatory process on the valves or myocardium.

The following are the guiding principles in the therapy of these conditions: In cases of acute endocarditis it is advisable to interrupt the pregnancy in every stage. In cases with decompensation, without demonstrable inflammatory changes in the heart, a conservative attitude is advisable, even in mitral stenosis. Women with valvular lesions without decompensation and without inflammatory changes in the myocardium or endocardium, provide no indication for the interruption of pregnancy.

Five Years' Experience with the Kielland Forceps.—S. Spitzer (*Zentralblatt für Gynäkologie*, June 2, 1923) applied the Kielland forceps in all those cases where the axis traction for the classical forceps had to be applied heretofore when the head was in the transverse position. One hundred and thirty-two cases are reported and the results were very satisfactory. In a high forceps application this new model reduces the transverse diameter by compressing the head from two sides and thereby facilitates the passage of the head when it is in the transverse position. Rupture of the uterus from turning the anterior spoon in the uterus need not be feared, provided the spoon is pushed up sufficiently high. Ruptures of the clitoris and the severe tears of the perineum as a result of the slipping of the forceps do not occur with this model. The springiness of the handles is a decided advantage and consequently the use of excessive force is eliminated. Injuries of the eyes from biparietal application is almost impossible. The completion of labor, which is almost impossible or can be accomplished only with great difficulty and with great danger for both the mother and child with the ordinary or axis traction forceps, is made possible with the Kielland

forceps. In spite of the wide field of its application, it is much less dangerous than both of the other types of forceps. However, it should be used only by those who are practically able to take care of difficult cases. In the cases of the head being rotated in the pelvic outlet, the classical forceps is more suitable.

Experiences with the Kielland Forceps.—Hans Hirschberg (*Zentralblatt für Gynäkologie,* June 2, 1923) finds that the use of the Kielland forceps frequently facilitates labor and is more sparing for the mother and child because the great dead space between the approximating blades of the forceps, which is not present in the classical forceps. Specially good results are obtained in the application of high forceps, if this is indicated. The delicacy of the handles is also a great advantage. The author warns against forceful rotation and advises the following of the rotation impulse of the head and to proceed with a gentle and searching hand as a mistake may be made in regard to the position of the head.

Sensation of Pressure on the Rectum, as Sign of Completed Expulsion of the Placenta from the Body of the Uterus.—F. v. Mikulicz-Radecki (*Zentralblatt für Gynäkologie,* July 7, 1923) asserts that in addition to the most important signs of the expulsion of the placenta from the uterus, namely, the rise of the uterus beyond the level of the umbilicus, the reduction in size and the angulation of the uterus and the advance of the umbilical cord, must be mentioned the sensation of pressure on the rectum, which the woman feels when the separated placenta lies in the canal of the cervix or in the vagina. Immediately after the appearance of this sign, slight pressure is sufficient to express the placenta. With the aid of this sign the frequent uncovering of the woman and the control of the abdomen are rendered unnecessary. However, the woman in labor must be instructed as to the occurrence of this sign.

Primary Lesions on the Internal Female Genitals.—Karl Herold (*Zentralblatt für Gynäkologie,* August 18, 1923) calls attention to the importance of recognizing the nature of the ulcerations on the vaginal portion of the cervix of the uterus. Gynecologists do not think of the possibility of a syphilitic primary lesion often enough. The epithelial defects in the vaginal portion of the cervix are a site of predilection for the spirochetes. The symptoms complained of were pains in the hips, groins and in the abdomen. On histological examination the danger of mistaking the lesion for carcinoma and sarcoma must be thought of.

Behavior of Thrombocytes in Climacteric Hemorrhages and Their Influence as a Result of Calcium Medication.—R. Hornung (*Zentralblatt für Gynäkologie,* August 11, 1923) endeavored to determine whether the changes in the mechanism of coagulation resulting from the dysfunctioning of the ovaries is due to climacteric changes. He injected ten c.c of a ten per cent. solution of calcium chloride intravenously and frequently found, no later than twenty-four hours at the most, a pronounced reduction in the number of blood platelets in every one of his cases. The hemorrhages were entirely checked after the first or second injection of calcium in eighty per cent of the cases. The hemorrhages were not controlled in eight per cent. of the cases.

Value and Limitations of Rectal Examination During Labor.—v. Mikulicz-Radecki (*Zentralblatt für Gynäkologie,* August 4, 1923) asserts that the vaginal examination during labor is and remains a more delicate, but also a more dangerous, method than rectal examination; the latter can never completely replace the vaginal examination. It requires a certain amount of experience. The student should be taught first the vaginal method because it is the most informatory in critical cases. It is possible to recognize the cervix of the uterus through the rectum provided it is still present, but a thin rim of the cervix is not palpable. The recognition of the bladder through the rectum is often difficult, as the feeling of the hairs is possible through the vagina after the bag has ruptured. It is almost always possible to determine the presenting part, even of the sacrum, except when it is still high over the pelvis. The diagnosis of placenta previa is very difficult. The pelvis can be easily palpated. Normal labors can therefore be easily conducted by rectal examination and in difficult cases the attempt may be made to do so. The mucous membrane of the rectum does not suffer from such examination.

Placental Transmission.—L. Jean Bogert and E. D. Plass (*Journal of Biological Chemistry,* June, 1923) made calcium determinations on the maternal and fetal serum by the direct method of Kramer and Tisdall. The calcium content of the fetal serum was found to be substantially higher than that of the maternal serum in every case investigated, the average difference being 1.8 mg. per cent. Magnesium was usually present in the same concentration in fetal and maternal serum, although in a few instances the fetal values were higher. No constant relationship between the calcium or magnesium content of the serum and the age or parity of the mother was observable. The serum calcium of the mother at the end of labor was usually below the physiological range for normal nonpregnant women, while the average maternal serum calcium is distinctly lower than the average value for normal women. The serum calcium of the child at birth is usually higher than the normal physiological range for adults.

Basal Metabolism and the Menstrual Cycle.—Glen Wakeham (*Journal of Biological Chemistry,* June, 1923) gives the results of ninety-eight basal metabolism determinations on twenty-four subjects under unusually favorable conditions for observation. The following facts were brought out by this study: There is a distinct fall in basal metabolism about the beginning of the menstrual period, a rise within the week or ten days prior to menstruation, and a gradual return to normality within seven or ten days following it. The following tentative suggestions are offered: That basal metabolism is considerably higher on the average in those engaged in strenuous labor than in those of sedentary occupations; that fluctuations in basal metabolism are less in those living under uniform conditions than in those whose mode of life is more varied; that the basal metabolism variation due to the menstrual cycle, while in every case less than the average daily fluctuations, is greater in active individuals than in sedentary individuals; that causes which produce too frequent menstruation are likely to be accompanied by high basal metabolism, and those which delay or suppress menstruation by low basal metabolism.

How Does Increased Intraabdominal Pressure Affect the Kidneys and to What Extent May This Effect Be Utilized Therapeutically? W. Gessner (*Zentralblatt für Gynäkologie,* September 22, 1923) asserts that it has been shown experimentally that circulatory disturbances may be produced in the kidneys by raising the intraabdominal pressure, the clinical picture of which absolutely resembles that of the kidney of pregnancy. This requires, not the socalled toxins of pregnancy, but only a fatty, pasty habitus, which constitutes the prerequisite for the increase in the abdominal pressure and for the ischemia of the abdominal viscera and particularly that of the kidneys. In case of postpartum hemorrhage, the author recommends the application of an enlarged Recklinghausen cuff, which is made to surround the abdomen and inflated as a pneumatic aortic compressor, and also the application of a marked pneumoperitoneum, which act as a hemostatic through the increased intraabdominal pressure. If necessary, this pressure may still further be increased by pressing the inflated rubber tube of the Recklinghausen cuff firmly against the vertebral column with the hand. In this manner the author was always enabled to control hemorrhage from the pelvic organs.

Pathological Anatomy of Corpus Luteum.—Emil Novak and R. W. TeLinde (*Bulletin of the Johns Hopkins Hospital,* September, 1923) in summarizing their study of the corpus luteum, state that it shows individual variations within physiological limits, the most important of these being cystic distension of the corpus and an excessive degree of hemorrhage. Corpus luteum abscesses are very frequent. Corpus luteum cysts may be subdivided into the recent type and an old type, and the same classification holds good for corpus luteum hematomas. These are commonly due to excessive hemorrhage into the lumen during the stage of vascularization. The authors state that there is no reason why ovarian tumors of supposedly lutein origin which have been described should not occur, and growths, chiefly carcinomas, have been observed by them in which such an origin was suggested morphologically. The condition spoken of as multiple lutein cysts of the ovary, found with some cases of hydatidiform mole and chorioepithelioma and sometimes erroneously designated as multiple corpus luteum cysts, is due to a widespread luteinlike transformation of the theca cells in the atretic follicles.

Medicolegal Notes.

TESTIMONY TO FACTS NOT OBJECTIONABLE AS OPINION OF PHYSICIAN IN ANOTHER SCHOOL OF PRACTICE

In an action against a sanipractor, or drugless doctor, for negligent diagnosis and improper treatment of plaintiff's minor son, the Washington Supreme Court holds, Wilcox v. Carroll, 219 Pac. 34, that the testimony of allopaths, employed by the plaintiff after defendant had abandoned the case, and who performed an operation for appendicitis, as to their diagnosis of the disease, their operation, and various other matters in connection with their treatment of the case, was admissible as testimony of facts found by the operation as well as by their preliminary examination, and was not objectionable as expert testimony by physicians belonging to another school of practice.

DIFFERENCE OF OPINION AS TO ADMINISTRATION OF ANESTHETICS.

In an action against two physicians and surgeons for malpractice in the administration of an anesthetic, in which negligence was alleged in administering ether or chloroform instead of a local anesthetic, and without first giving the patient a heart stimulant, the testimony showed a difference of medical opinion, expressed by physicians and surgeons of unquestioned standing and reputation in the neighborhood, the majority testifying that everything done by the defendants had been in accord with the best modern surgical practice. It was held, Remley v. Plummer, 79 Pa. Superior Ct., 117, that the defendants were not negligent for having adopted the view held by the majority of their brethren who testified. "In cases where authorities differ or 'doctors disagree' the competent physician is only bound to exercise his best judgment in determining which course is on the whole best."

NEW YORK DOCTRINE AS TO LIABILITY OF CHARITABLE HOSPITALS.

After much discussion, the New York Appellate Division says, in Phillips v. Buffalo General Hospital, 202 N. Y. Supp., 572, that the law has been settled in the State of New York that a charitable corporation is not totally exempt from liability for the negligent acts of its employees committed within the line of their employment. It is equally well settled that a hospital maintained as a charitable institution is exempt from liability for the negligent acts of physicians and nurses in the treatment of patients. Such exemption from liability has finally been placed squarely upon the ground that the patient, upon becoming an inmate of such charitable institution, waives all claims of liability growing out of the negligent acts of physicians and nurses which occur during treatment. This is true, even though the patient injured by the negligent act of a physician or nurse is a paying patient. Such a payment is regarded as a contribution to the income of the hospital, to be devoted, like its other funds, to the maintenance of the charity.

In the present case the plaintiff was a paying patient, the defendant a charitable corporation, maintaining a hospital. The plaintiff, while being treated, was burned by a hot water bottle negligently placed in the bed with her, while she was unconscious, by an orderly. It was conceded that the defendant would not be liable in an action for negligence if the hot water bottle had been placed in the bed by the nurse in charge of the case. A recovery was permitted in the court below, however, upon the theory that the orderly was a servant of the defendant, occupying the same relation to it as the superintendent or assistant superintendent, and that for his negligent act the defendant was responsible, under the doctrine of respondeat superior.

Reversing this judgment, and dismissing the complaint, the Appellate Division says: "It is true that the defendant might be held liable for the negligent act of one of its servants, committed within the scope of his employment, which resulted in an injury to a third person not a beneficiary of its charity. To hold, however, that the plaintiff, upon becoming a patient in the defendant's hospital, impliedly waived all right of action for damages growing out of injuries which might be caused by negligent acts of a nurse, but did not waive such rights of action if the injury should be caused by an orderly, seems illogical and unjustified. There is no reasonable basis for such distinction."

PHYSICIAN'S ACCOUNT BOOKS AS EVIDENCE

Where a physician presented a claim against his father's estate for professional services rendered during a period of five years, the Pennsylvania Superior Court, Croushore's Estate, 79 Pa. Superior Ct., 286, held that, although the question whether a physician's account book can be received in evidence as a book of original entries seems to be still in doubt in the State of Pennsylvania, where the doctor, who kept the books, testified, and use was freely made of the books without objection, the books were competent to serve as a memorandum, used by the witness to refresh his memory and in corroboration of his testimony.

The deceased in his will directed that his son should receive credit for all professional services rendered to him, and it was held that the son should not, in the circumstances, be hampered in proof of his claim by his relationship.

INSUFFICIENT EVIDENCE TO PROVE PRESENCE OF PATIENT WITH SMALLPOX IN HOSPITAL.

In an action against a hospital for negligence of its employees in permitting a patient to contract smallpox from another patient, the hospital claimed that there was no case of smallpox in the hospital while the patient was there. Evidence of the presence of a man in the hospital whose face looked is if he might have smallpox was held too conjectural, in view of the fact that expert physicians could not make a reliable diagnosis of the disease from such an appearance alone, without continued observation, because of its baffling resemblance to several other common diseases of the skin. Such an inference would not support the conclusion that any of the employees of the hospital, including the nurses, knew of the existence of any case of smallpox in the hospital. Gadsden General Hospital v. Bishop, Alabama Supreme Court, 96 So. 145.

HOSPITAL INTERN'S RIGHT TO COMPENSATION UNDER WORKMEN'S COMPENSATION ACT.

The New York Court of Appeals, Bernstein v. Beth Israel Hospital, 236 N. Y., 268, 140 N. E., 694, affirming 205 App. Div., 419, 199 N. Y. Supp. 740 (of which an abstract appeared in the Medical Journal and Record of January 16, 1924, p. 128) holds that the fact that interns in this hospital (unlike those in many others) receive no money for their services, but only lodging, board and uniforms, does not defeat their right to an award of compensation under the New York statute, such recompense being wages, as defined by section 3, subd. 9.

The hospital does not carry on its business for pecuniary gain. It elected, however, to insure. The insurance carrier, having accepted its premium, is by section 55 of the compensation statute, added in 1922, bound to the same extent as if gain rather than benevolence had inspired the activities of the hospital.

The Treatment of Deafness*

Brief Review of Current Theories and Methods. Suggested Modifications More Logically Based on the Problems Involved.

PHILIP D. KERRISON, M.D.,
New York City

Probably at no previous time have deaf people in larger numbers been in the hands of untrained and irregular practitioners than today. Are we as practical otologists in any way responsible for this fact?

It has seemed to me that we are less logical in our treatment of deafness than in our treatment of any other otological problem; that we have accorded to certain measures a position of importance entirely unjustified by their results; in other words, that we have got into a rut, which has to some extent discouraged constructive effort and thereby limited our advance.

That, as I see it, is one side of the picture. On the other hand, there are encouraging signs in a tendency toward a broader concept of deafness and the treatment problem. The question of extraaural foci of infection as an underlying factor in deafness is studied more widely and intensively than ever before. There is a growing willingness among progressive students of deafness to condemn openly whatever agency in treatment, however timehonored, has not yielded results of definite value. The possibilities of advance along lines or pathways not heretofore traveled are in men's minds. New agencies as applied to the perceptive mechanism are under investigation by groups of young and competent observers. In short, there is a salutary awakening to the need of a restudy of the whole difficult problem of treatment from new, or at least from different, angles or viewpoints.

This paper is divided into three parts, which represent efforts in three directions: 1. To review current theories of local treatment; 2, to suggest a modified plan of treatment more logically based on the mechanical problems involved; and 3, to consider briefly the problem of treatment from other viewpoints.

PART I: CURRENT THEORIES OF LOCAL TREATMENT

Excluding all cases of chronic deafness due primarily to auditory nerve or labyrinthine defect or disorder, the classical treatment is based for the most part on one or other of two timehonored theories of the mechanics of sound obstruction:

1. *That of the occluded tube.*—It is assumed that this condition, causing retraction of the drum membrane and venous congestion of the tympanic mucosa, is in large measure responsible for the deafness present. Undoubtedly tubal disease has an important etiological relation to the incipient stage of most tympanic lesions. But that in advanced or long standing deafness tubal obstruction is more than a minor factor in the actual obstruction of sound waves, is disproved by the fact that its restoration to normal patency or condition *never brings even an approximate return of normal hearing.*

2. *That the drum membrane has become thickened, rigid, or in some way less mobile than in the normal ear,* and therefore does not respond as normally to sound waves. It is assumed that any agency, e. g., inflation or pneumatic massage, which causes forcible passive movements of the drum membrane, will improve sound transmission. This, I believe, is a particularly unfortunate popular misapprehension which in the past has to some extent beclouded the whole question of treatment. I am convinced that exactly the reverse is true in the vast majority of cases.

There is, of course, a third and major factor in the pathology of obstructive deafness, i. e., ankylosis or rigidity of the ossicular joints, and particularly, as in otosclerosis, fixation of the stapes within the oval window. Such changes, however, are so clearly beyond correction by any of the usual treatment measures as to have little bearing on their value.

The local measures in common use are so few in number as to be easily listed. Measures to relieve nasopharyngeal congestion; the use of bougies for tubal obstruction; medicated bougies for tubal congestion; Politzerization or catheter inflation to restore air pressure equilibrium; pneumatic massage, supposed to "exercise" both drum membrane and ossicles, practically complete the list. A moment's reflection will convince one that, with the possible exception of inflation, not one of these measures has any logical basis in the treatment of deafness except as based on one or other of the two hypotheses stated above.

If the commoner types of deafness were associated

*Read in part before the Section on Otology of the New York Academy of Medicine, January 11, 1924.

Copyright, 1924, by A. R. Elliott Publishing Company.

with increased rigidity or stiffening of the drum membrane, the treatment, so far as it concerned this pathological feature, would be comparatively simple; for it would not be difficult by inflation or some form of pneumatic massage to lessen this rigidity. But experience has abundantly shown that treatment along these lines does not relieve deafness; and it would seem that this failure should have *per se* considerable weight as evidence that this theory of the mechanics of deafness is unsound.

The relaxed membrane.—This argument is based on the proposition that relaxation of the drumhead is one of the commonest of pathological changes in obstructive deafness. By relaxed membrane I do not necessarily mean the exaggerated forms in which the membrane in whole or part is seen to balloon out into the canal during Valsalva inflation, nor do I refer particularly to the cases of extreme atrophy in which the entire membrane is seen so plastered against the tympanic wall as to be hardly recognizable. I include under this term the far more numerous but less conspicuous forms in which the entire membrane or parts of it suffer a loss of normal tonicity not easily measured by inspection, but which counts nevertheless as a potent factor in the retrograde processes leading to deafness.

Every experienced aurist will admit that, barring the purest types of otosclerosis, retraction of the membrane is present in some degree in the vast majority of cases of tympanic deafness; also that the retraction in these cases is not a temporary condition, but usually of long standing. It is impossible to believe that a comparatively rigid and inelastic membrane can be stretched into an abnormal position and there retained over a period of months or years without undergoing some degree of structural change, i. e., relaxation. Furthermore, if such relaxation did not exist, the drum membrane, when released by inflation or cocainization of the tube, would spring back into a perfectly normal position. As a matter of fact, such complete correction of position does not as a rule take place. If, from a consideration of these more or less obvious facts, we conceive of prolonged retraction and relaxation as being in a sense equivalent terms, we shall have little difficulty in accepting the theory of a relaxed drumhead as a common factor in the mechanics of sound obstruction.

Let us accept for the moment as a working hypothesis the theory that relaxation of the drumhead is almost invariably present in obstructive deafness, and consider just how this influences the process of sound transmission.

Drumhead relaxation as part of a vicious circle leading to deafness.—As soon as any portion of the membrana tensa loses any part of its normal tonicity, the effect of sound waves upon the ossicular chain must be reduced; for it is obvious that the relaxed portion of the membrane will be able to move within a certain range, increasing as relaxation progresses, without communicating its motion to the hammer handle and ossicles, and that to this extent sound transmission must be impaired. In other words, it should require no argument to prove that the force of a sound wave must first "take up the slack" of a relaxed drum membrane before it becomes operative upon the ossicular chain. So far we are dealing with facts which are obvious and incontrovertible. But there is another exceedingly important direction in which relaxation may operate to reduce hearing power, i. e., by disturbing the mechanism controlling the passage of sound waves through the labyrinthine fluids. With marked relaxation of the posterior segment, for example, it is conceivable that, under the impact of sound waves, exaggerated inward movements of this portion may cause such abnormal synchronous pressure upon the membrane of the round window as to reduce its compensatory function, and thereby partially block the movements of the cochlear fluids. This is an important factor in the mechanics of sound obstruction which has apparently escaped the attention of students of deafness.

As soon as relaxation of the membrane has reached the point at which ossicular response to sound waves is definitely reduced, it is conceivable that progressive loss of ossicular mobility—i. e., rigidity of the ossicular joints from relative disuse—begins. From this point the pathological process in its effect upon hearing power is a dual one, progressive loss of tonicity in the membrana tensa and progressive increase of ossicular rigidity marking the advance of the disease. Nor is the direct chain of evils yet ended; for there is reason to believe that sooner or later another inevitable factor is added in the condition of the acoustic nerve itself which, no longer receiving its normal stimuli in normal force, undergoes a sort of functional retrogression or torpor. Such a hypothesis, at least, seems necessary to explain the functional status in the later stages even of cases apparently beginning as purely tympanic lesions, when a degree and type of deafness are reached which can hardly be explained except by the assumption of auditory nerve involvement.

It is time for us to think logically of this important factor, and say that in all types of auditory impairment, even in those usually regarded as characteristic of purely tympanic origin, a degree of deafness which our common sense and our acquired knowledge tell us could not be produced by any induced lesion of drum membrane or ossicular chain, must mean also involvement of the acoustic nerve.

To epitomize: In the progress of a chronic obstructive lesion, three consecutive factors in the production of deafness regularity arise: 1, impaired transmission through relaxation of membrana tensa; 2, reduced ossicular mobility through relative ossicular disuse; and 3, slowly progressive acoustic nerve torpor through gradual cutting off of normal sonorous stimuli.

It is not, of course, intended that the above shall be regarded as my conception of the complete picture of the tympanic pathology of obstructive deafness. The three stages there described represent, however, not only usual phases, but most important factors in the mechanical obstruction of sound waves. They supply our best clues to a rational scheme of local treatment.

In the light of the foregoing discussion, let us consider for a moment the effect on hearing of any scheme of local treatment in which routine inflation plays an important rôle. In attempting such an appraisal, one must differentiate between the immediate and the ultimate results.

Initial effects of inflation.—With a patient suffer-

ing from chronic obstructive deafness, the first inflations usually bring a sense of comfort and relief and may result in an appreciable gain in hearing. This is a quite logical result. The retracted position of the membrana tensa has been corrected and air pressure equilibrium restored. The drum membrane, therefore, responds more effectively to sound waves and transmits these impressions, or movements, more effectively to the ossicular chain. The hearing is, therefore, temporarily improved. According to my experience, an apparently progressive gain in hearing is frequently obtained up to the fourth or, more rarely, the fifth or sixth inflation, after which we shall do well if we are able by this method to maintain the maximum limit so far obtained.

Of the ultimate results of inflation one cannot speak so favorably. The patient who is subjected to periods of treatment alternating with periods of rest usually shows quite marked variations in hearing power at different times. After several months without treatment, he may have relapsed to the functional status of the first treatment period, from which, however, a short course of treatment brings substantial recovery.

Finally there comes a time, perhaps in one, two, or more years, when by careful tests the aurist's best efforts fail to bring the hearing up to the maximum limit of the first treatment period. As soon as this point is reached, i. e., when the original peak of functional gain can no longer be reached, the retrograde sequence of events is definitely established. From this point, the functional curve is downward.

Logic of functional changes as based on changes in tension.—Whoever under good illumination has studied the effects of Valsalva inflation or of socalled massage as seen through a Siegel otoscope, cannot fail to have noted the great disparity in cases of deafness between the movements of the membrana tensa and those of the hammer handle. Even with moderate relaxation, the two segments of the membrane are seen to execute quite extensive movements into the canal while the movements of the hammer handle may be so slight as to be difficult to detect. Reasoning from this observation, it is clear that routine catheter inflations, acting in like manner, must sooner or later cause further anomalies of tension. If, therefore, we remember that in whatever degree the normal tonicity of the drumhead is lost in like proportion will the influence of sound waves upon the ossicular chain be reduced, the effects of ill advised, or too forcible, or too frequently repeated inflations will not be difficult to comprehend.

If this sequence of events has been fairly portrayed—if I have not been illogical in my analysis of results—surely there is reason for some modification of current theories or methods.

PART II: LOCAL TREATMENT OF OBSTRUCTIVE DEAFNESS

The following discussion of treatment is based on twenty years' experience, made up in good part of blind following of old paths leading nowhere, and of subsequent eliminations and modifications.

We shall probably all agree that the first step toward a rational scheme of local treatment—of any disease—would be a careful elimination of all useless procedure.

In the following outline of treatment, I shall try, wherever a departure from the usual routine is suggested, to give the basis, or reasons, therefor.

Inflation.—The first treatments should follow the usual routine, i. e., catheter inflation at short intervals, preferably on every second or third day. Rapid hearing tests should be made before and after each inflation and the results accurately noted on the history card. These frequent tests are important and serve two purposes: 1, to determine temporary variations of function; and 2, what is far more important, to gauge any cumulative or progressive gain in hearing which may result. According to my experience, the maximum hearing gain is usually obtained by the fourth, fifth or sixth inflation. As soon as it is clearly demonstrated that no progressive improvement is being made—i. e., that the maximum result by this method has been reached—I believe that inflation as a routine measure should be discontinued. This belief is based on my experience that from this point more can be accomplished in the interest of permanent betterment of hearing by judicious treatment of the pharyngeal, or fibrocartilaginous, portions of the eustachian tubes than by frequent inflations, and that the drum membranes are thereby relieved of a strain which may cause further anomalies of tension and ultimately work quite serious injury to hearing.

Note.—I believe that the real explanation of the persistent routine use of catheter inflation is the universal and very natural desire for immediate results. As a matter of fact, however, the short lived functional gain following inflation is frequently the most direct available evidence of a nonfunctionating tube which, by reason of its resistance to the return air current, maintains for a time a distended tympanum, just as later it leads to negative air pressure and retraction. The logical indication, therefore, is not for inflation, but for careful local treatment of the pharyngeal end of the eustachian canal.

Eustachian canals.—I want to emphasize two points which seem to me established by experience: 1, that catheter inflation *per se* exerts no influence whatever of therapeutic value upon a chronically congested tube. If any influence be exerted, it is purely temporary; 2, the frequent passage of eustachian sounds or bougies does not materially help to restore a diseased tube to a normal condition. On the contrary, with allowance for exceptional cases of actual localized adhesions or constrictions, the frequent passage of even a small bougie through and beyond the isthmus may increase a tubal lesion and do positive harm.

If the foregoing conclusions are well founded, it follows logically that we shall obtain surer and quicker results, and in the final analysis accomplish more of permanent value to the patient, if we limit our treatment of the tube, a, to the application of appropriate drugs; and b, this failing, to direct surgical measures for the reduction of chronic congestion, edema or hypertrophy of the pharyngeal end of the canal.

The choice of drugs is so largely a matter of personal experience as to be inappropriate for discussion before a body of otologists.

As to method of application: it is hardly open to question that tubal disease begins usually or always in the pharyngeal end of the canal. Just as cocaine

or adrenalin, applied to this portion, usually clears the whole canal, so astringents or other drugs, confined to this region, usually exert their influence throughout the entire length of the tube. In my experience, a larger percentage of tangible results is obtained from drugs confined to this restricted field than from the same drugs applied by sounds or applicators throughout the entire canal.

Aside from their convenience in cleansing the nasal passages, nasopharyngeal sprays have little or no value in treatment. On the other hand, periodical irrigation of the nasopharynx with a warm solution of normal salt or of some mild antiseptic solution are of positive value in relieving nasopharyngeal and tubal congestion. Occasional postnasal irrigation with a warm solution of argyrol of two per cent. strength is of unquestionable value in a very considerable proportion of cases.

The treatment mentioned, though exceedingly simple, is rational, theoretically constructive, and should help to stabilize whatever functional gain results from the short course of inflation.

Naturally there are cases in which the results of the treatment above outlined are disappointing. While the nasopharyngeal condition may show obvious improvement, there may be no evidence of any improvement in tubal function. Such cases call for careful reexamination.

Valsalva catheter inflation test.—This test is simply a comparison of the results of Valsalva inflation (or Politzerization) with those of catheter inflation. If, for example, by the Valsalva method the patient finds unusual difficulty, i. e., requires unusual force, to inflate the ear while the otoscopic sounds during catheter inflation show that the tympanum is easily and fully inflated under moderate pressure, one may safely infer that the obstacle to the air current is at the mouth rather than within the depths of the canal.

Direct inspection with an electric pharyngoscope will throw considerable light on certain cases of obstinate tubal insufficiency. One may find, for example, a degree of congestion, edema or hypertrophy of the mouth of the tube easily accounting for practical failure of function in a tube quite open to catheter inflation. When this condition fails to respond to simpler measures, incision through the congested or edematous portion may through withdrawal of blood or subsequent tissue contraction bring about restoration or at least improvement of tubal function.

Surgical treatment.—The accompanying figures represent instruments designed by the writer for use in this field. Fig. 1 shows the probe, and Figs. 2 and 3 two knives for incision of the anterior and posterior lips respectively. When the nasal passage and pharyngeal end of the canal have been cocainized, the knife, whichever is to be used, is passed catheter fashion through the nose and introduced by slight pressure into the tube. If sharp, a clean incision may be made as the knife is withdrawn. A little practice will enable one to pass these knives without injury to turbinates or other intervening structures. Should it seem wise to incise both pillars, some days should intervene to insure against possible adhesions. While the blades of these knives may seem at first glance unnecessarily wide, a moment's reflection will show that this is a provision of safety, since the incisions are intended to be restricted to the mouth of the tube, and not to extend deeply into the lumen of the canal.

In the limited number of cases in which I have used this procedure, the results have seemed favorable. There is sometimes a quite free bleeding for a minute or two, which ceases automatically. I have seen no troublesome inflammatory reaction. It can

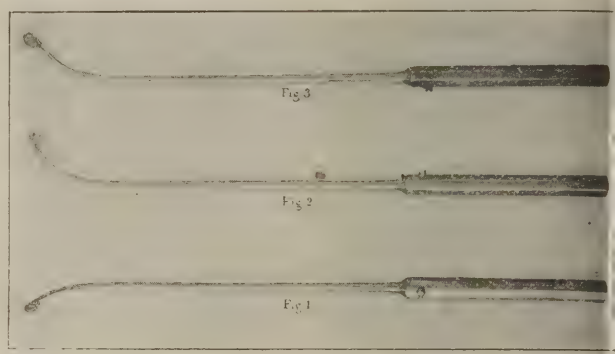

Fig. 1.—Eustachian probe.
Figs. 2 and 3.—Eustachian knives for incising anterior and posterior walls respectively.

be of value only in carefully selected cases. It is mentioned only as supplying a useful link in the chain of treatment measures for certain cases in which an obstructive condition or lesion definitely localized in the pharyngeal mouth of the tube blocks the way to results.

It is clearly illogical to expect any sustained improvement in the position of the drumhead until the tubes are brought into a relatively normal condition; and the treatment above outlined has seemed to me to give in general the most satisfactory results in this direction.

The drum membrane.—I believe that, more than we usually take into account, the drum membrane itself calls for direct attention in the treatment of obstructive deafness. If we inspect the membrana tensa critically, even after we have secured a fairly open and presumably functionating eustachian canal, we are apt to find some degree of retraction. The cause of this may no longer be a condition of negative air pressure within the tympanum, but rather the structural habit or set of the membrane after years of tubal congestion and insufficiency. The membrane, therefore, like any fabric long inured to one position, tends after inflation gradually to lapse into the habitual but abnormal position of retraction.

The paper disc (a digression).—Many of us who have seen some of his patients know that the late Dr. Clarence John Blake made frequent use of paper discs, applied to the drum membrane, in the treatment of certain types of deafness. I have under my care one of his patients, formerly a resident of Boston, who states that the replacement of these discs constituted a regular feature of his treatment. Either he observed favorable results from this procedure, or hypnotized himself into a belief as to its value, or, as seems to me more probable, saw in it a logical step in his effort to rebuild or reestablish the conducting mechanism on more physiologically normal lines.

Writing in 1921, D. Harold Walker described the cases of four patients, all suffering from vertigo of

distressing type and all showing physical signs of relaxed drum membranes. In all of these cases the disturbances of equilibrium were promptly relieved "by the simple application of a rice paper splint."

Apparently Blake's advocacy and Walker's paper fell on otologically deaf ears. Yet there are tympanic conditions which illustrate quite clearly the use of paper discs in the treatment of deafness.

We know, of course, that various measures, e. g., multiple incisions, have at various times been proposed for correcting abnormal relaxations; there is, however, but one rational line of effort at our disposal, i. e., to replace *and retain* the membrane in an approximately normal position, thereby giving nature a chance to restore normal tone. There is no other logical means to this end.

The paper splint is applied as follows: a disc of rice paper is cut to conform to the more relaxed or atrophied portion—i. e., the portion most noticeably defective in structure or tension, and therefore least fitted either to transmit sound waves or to withstand even slight changes in tympanic pressure. After being soaked in alcohol, this is introduced deeply into the canal and placed against the posterosuperior canal wall. It is then slid into position and adjusted with a tightly wound cotton applicator. Such a splint, properly applied, will hold its position for weeks, though tending to move toward the nearest canal wall. Its adherence to the membrana tensa is so close that removal is difficult or impossible without soaking. If, therefore, the disc is applied immediately after inflation, its value in supporting a relaxed membrane in a relatively normal position becomes clear. The hearing may or may not show immediate gain. The purpose, however, is to reestablish more normal position and tension. If we can accomplish this, we can afford to wait upon improvement in hearing, which should logically follow.

Summing up.—If the steps above outlined have been successfully carried out, we should have the following tangible results: 1, A better functionating eustachian canal; 2, a more normally placed drum membrane; and 3, a more normal balance between drum membrane and ossicles. Functionally these changes should be translated into improved hearing —not necessarily of the spectacular type which occasionally follows immediately upon inflation and is as quickly lost. Rather it should be a clearer definition for all sounds which, however moderate in degree, should be better sustained.

The ossicular chain.—We come now to the most difficult problem in local treatment: *how without injury to the drum membrane to exercise or reeducate the ossicular chain to more effective transmission of sound waves.* We cannot expect by any exaggerated or unnatural passive movements of the membrana tensa to improve sound conduction, because the resulting strain upon the membrane will first counterbalance and ultimately far outweigh any advantages from improved ossicular mobility.

Utilization of sound waves.—Many years ago I published a short paper on the utilization of selected sound waves from a specially designed set of large tuning forks for exercising the ossicles in obstructive deafness; and nothing in my subsequent experience has disturbed my belief that such a method provides a logical means to this end. We know that impressions of sound reach the inner ear chiefly through vibrations of the conducting mechanism excited by sound waves from without; that in obstructive deafness loss of tone perception begins at, and extends from, the lower end of the musical scale. Why, then, is it not a logical procedure to make use of selected sound waves of low pitch but relatively great intensity to exercise the ossicles in just those movements (sounds) for which their mobility is known to be impaired? If, for example, it be shown by careful tests with small forks that the hearing is all but lost for a given note, e. g., 128 d. v., why may we not exercise the conducting mechanism for that particular note by means of larger forks of the same and of lower pitch whose greater amplitude of vibration is sufficient to throw the drum membrane into more vigorous vibrations?

My forks were made according to my own specifications. The set consists of twenty-nine forks which without clamps produce every full tone of the musical scale in the four octaves from thirty-two double vibrations to 512 d. v. With clamps the lower forks produce tones one octave lower, or down to 16 d. v.

Method of use.—Let us suppose that the superficial or approximate lower tone limit is shown to be 160 d. v.; then this fork and three or four others immediately below it in the musical scale (144, 128, 120, 107 d. v.) are used as follows: First the highest fork, 160 d. v., is set in maximum vibration and held with the flat surface close to the ear until its tone is no longer heard. This may be repeated once or twice. Then the next lower fork, 144 d. v., is used in the same manner, and so on through the series of successively lower forks until one is reached which is not appreciated as sound. Manipulated in this way, forks two to four notes lower will usually be heard.

Risks inherent in prolonged exposure to sound waves.—That careless or irrational use of sound waves entails some risks goes without saying. We have only to cite the well known experiments of Wittmaack as to the organic changes in the cochlea following prolonged exposure to a single tone, to enforce this observation. The late Dr. Blake, of Boston, recorded the results of experiments in which he assisted Professor Politzer, in which sound waves from electrically activated tuning forks were used. He stated that "these experiments showed apparently an improvement in hearing in cases of rigidity of the articulations of the ossicles." In his experiments, however, the ear was subjected to the continuous influence of a single tone for three to four minutes, and the experiments were discontinued on account of the evidence of auditory fatigue and a peculiar form of continuing or "after" tinnitus. These statements of Blake are of practical significance from two viewpoints: 1, as emphasizing the danger of prolonged exposure to a single sound wave; and 2, as suggesting the possible influence of sound waves in stimulating the acoustic nerve—i. e., since auditory fatigue would seem necessarily to imply a primary period of stimulation.

It will be noted that in the use of tuning forks outlined in these notes, auditory fatigue is eliminated or at least reduced to a minimum by, a, the quick shifting from one tone to another in the descending musical scale; b, by the rapid automatic diminution

of intensity in the vibrating fork; and c, by the fact that the forks used begin with the apparent lower tone limit—i. e., that they represent tones for which the nerve is more or less protected by impaired transmission.

As I wish to discuss briefly the physiological influence of sound waves from another viewpoint, I shall defer for the moment their further consideration.

PART III: THE ACOUSTIC NERVE IN DEAFNESS

Earlier in this paper I ventured upon a definite statement that the acoustic nerve is always involved in cases of advanced deafness. While I have not seen this categorically stated before, I believe that it is a view to which most experienced aurists will subscribe. Whoever has failed to receive this impression, has only to reexamine his deafer patients and try to explain their functional status without this assumption, to be convinced of its truth and importance. If we accept this hypothesis, we are brought at once to a second deduction, i. e., the necessity of more careful consideration of the acoustic nerve in relation to deafness and treatment.

There is evidence from various sources, independent and unrelated, of renewed or awakening interest in the nervous element in deafness—even in deafness of the common type often rather loosely spoken of as catarrhal or tympanic. For some time I have been interested in experimental tests of the reactions of deaf individuals to the galvanic current, only to find recently that similar experiments have been, and probably are being, made by men or groups of men in other centres—Philadelphia, Brooklyn, Iowa City. The influence of the high frequency electrical currents in deafness and their therapeutic value, if any, are being studied by groups of competent observers. The x ray current, an agency bristling with risks and capable of producing coincidently temporary stimulation of the acoustic nerve and structural changes ultimately harmful, is being used and advocated by physicians not otherwise affiliated with otological practice. It is also being used experimentally by certain regularly trained aurists. Powerful industrial corporations, backed by enormous resources of capital and perfectly equipped research laboratories, have embarked upon experimental investigations which seem destined to throw light on the nervous element in deafness. In short, there is apparently a growing appreciation of the need of a much broader view of the nature of deafness and of the difficult and intricate problem of treatment.

It is clear that the treatment of the acoustic nerve in cases of deafness can be considered, if at all, only from the following viewpoints: 1, the possibility of local, or direct, stimulation; 2, administration of drugs; 3, elimination of injurious agencies; and 4, hygiene, or regulation of the patient's life.

Direct stimulation.—If we consider the theoretical potentialities of such agencies as tonal stimulation, galvanism, diathermy, the much disputed x ray, and other methods, in the treatment of deafness it is clear that any value they may possess must be attributed chiefly to their direct influence upon the acoustic nerve.

Tonal stimulation.—By this I mean the tuning fork exercises already described. For directly influencing the acoustic nerve, however, they may with advantage be varied by substituting bone conduction for air conduction. Through this medium, tones some octaves lower than are heard by air conduction will often be heard without difficulty; and with large forks placed against the mastoid or lightly against the tragus (i. e., never with sufficient force to close the meatus), there is an appreciable sense of percussion or mass movement in addition or that of tone perception. By way of illustration, let us suppose a case of obstructive deafness in which the lower tone limit has been found to be 160, 170 or 196 d. v. Presumably the nerve has long since ceased to respond to the lower tones as transmitted through the air. What more logical or physiologically rational form of nerve stimulation can be imagined in such a case than one which will force this nerve to respond for very brief periods to tonal stimuli two or more octaves below those commonly reaching it through the disabled conducting apparatus?

Galvanism.—Theoretically the use of the galvanic current in nerve deafness finds justification on the following grounds: 1. The fact, generally accepted by electrotherapeutists, that application of the cathode, or negative electrode, to the vicinity of a nerve causes excitation, or stimulation, of the nerve in question; whereas application of the anode, or positive electrode, causes the opposite (sedative) effect, i. e., creates a condition of diminished excitability. 2. A galvanic current of sufficient strength regularly causes typical reactions of the vestibular nerve (nystagmus, vertigo, and other disturbances). It seems a logical deduction, therefore, that an electric force known to influence the vestibular branch of the eighth nerve, will also reach and influence the acoustic branch of the same nerve.

It is clear that any agency theoretically capable of stimulating a disabled acoustic nerve to better hearing, may also irritate the same nerve to louder tinnitus. We know that many deaf people suffer also from loud head noises; and that there are others with whom tinnitus is absent or so slight as hardly to attract the patient's attention. It has occurred to me that such differences may perhaps admit of a tentative hypothesis: i. e., of hyperirritability of the end organs of the acoustic nerve as a basis of loud tinnitus, and of hypoirritability of the nerve in cases in which tinnitus is slight or absent. With this hypothesis in mind, it is at least theoretically clear that the galvanic current may be beneficial in certain cases and injurious in others.

With me galvanism has taken its place as an occasionally useful agent in the investigation of obscure types of deafness, in which the reactions may throw light on the condition of the nervous mechanism of hearing. It has seemed beneficial in a certain small proportion of cases and harmful in others. Where unfavorable results occur, they will probably be most often in the direction of increased or induced tinnitus.

With *high frequency electric currents* my experience is as yet too limited to justify more than passing comment. It is a most interesting possibility—in theory filling an important gap in the essentials of treatment. Stripped of technical verbiage, it is an agency which enables one to deliver heat to structures below the surface. As such its theoretic therapeutic possibilities are sufficiently obvious. So also, in care-

less hands, are its potentialities of injury. So far as my observation of results have gone, they have on the whole been favorable and encouraging.

With regard to other possibilities of influencing the acoustic nerve: Drugs, elimination of injurious agencies, hygiene, etc., have been mentioned so frequently in connection with all forms of disease as almost to have ceased to register in the mind of the average reader. It has seemed to me, however, that all these agencies might have a more definite significance in the treatment of deafness if considered solely with reference to their influence upon the acoustic nerve.

Elimination of injurious agencies.—First under this head come the extraaural foci of infection from which the ears may suffer indirectly. Of these the most important are: infected tonsils, dental root infections, chronic infections of the nasal sinuses, gastrointestinal infections. Some comparatively recent papers of considerable interest have been apparently based on the hypotheses that a majority of all cases of chronic deafness have their origin in some extraaural infection from which the poison reaches the ear most often by way of the lymphatics. In some respects these papers have led to erroneous deductions in suggesting results from operations for the elimination of such septic foci, which can not as a rule be obtained. Even more misleading have been the reports of cases of deafness in adults, in whom spectacular improvement of hearing has followed tonsillectomy. Such cases are exceedingly exceptional. It cannot be too positively stated that whoever advises tonsillectomy, removal of infected teeth, and other measures, with the expectation of marked improvement of hearing, is likely to find later that he has deceived both himself and his patient. That is one side of the question, which the correlation of experience in any considerable series of cases will definitely establish.

There is another point of view which must not be overlooked. Naturally the partially deaf person, who is constantly or intermittently absorbing septic matter in amounts however small, will respond less favorably to any treatment, local or constitutional. There are also authentic case histories in which the eighth nerve has borne the brunt of an attack by such poisons. The search for and elimination of such a focus is therefore one of the most positive and logical indications, which in cases of deafness may help to limit its advance, and may in certain cases be followed by some functional gain.

Tobacco.—The question of the tobacco habit is in many cases not an easy problem. So many excessive smokers escape obvious injury, and so many nonsmokers suffer auditory defects, that dogmatism is in most cases out of order. To me the most satisfactory approach to this subject is by a quite frank treatement or discussion, explaining to the patient the fact that tobacco is undoubtedly an acoustic nerve poison in certain cases and that it may also promote abnormal changes within the tympanum; that it is impossible to determine definitely how far tobacco is operative in his case, or to what extent its elimination may help to turn the scale toward functional recovery. On this basis one may enlist an intelligent patient's interest and real cooperation in experiments in partial or total abstinence the results of which, if favorable, may prove to his very great advantage.

Hygiene; regulation of the patient's life.—I have frequently heard the statement that among city men who enjoy camp life, those whose hearing is impaired often experience a definite hearing gain after a week or two in the woods. This, if true as I believe it is, should lead at least to a logical deduction: i. e., as to the important bearing on hearing of any readjustment of the patient's method of existence which will improve his general vitality. It also provides a composite picture of all that might contribute to the end in view—i. e., regular hours, exercise in the open air, plenty of sleep, simple wholesome diet, elimination of all that goes under the name of dissipation, freedom from brain fag, or strain. Impossible of realization as all this may seem in a city environment, we have here all the elements out of which to construct a compromise scheme of existence which would help a large majority of these patients.

SUMMARY

To summarize: whatever increases general vitality or vigor tends to improve audition; and whatever hearing gain accrues from such means must be attributed to a better functionating nerve rather than to improve sound transmission. If we use every safe and rational means of stimulating the endorgans of the acoustic nerve; remove all discoverable sources of infection or of nerve depression or injury, and endeavor to raise the tone or functional activity of the perceptive mechanism by improving general nervous tone and vitality, we do all that in the present state of our knowledge is possible in this direction. If we neglect this phase of the problem as of negligible practicability or importance, we neglect a factor which is logically a part of any rational scheme of treatment.

Only as we take into consideration all the factors in the production of deafness and all the potentialities of treatment logically applicable to their correction, shall we obtain for the average patient a hearing gain of permanence or value.

I personally believe that the most important field in otology in the immediate future will be found in the treatment of deafness; that the acoustic nerve and its reactions must be made the subject of more intensive study; that local treatment must aim less at the immediate subjective relief of the patient and more at the slow building up of more normal conditions of intratympanic tension or balance. Definite progress along these lines is the most urgent demand upon otology today.

CONCLUSIONS

1. The first essential in an attempt to amend any system of treatment is the elimination of all useless or harmful procedure.

2. Routine catheter inflation is dangerous to hearing on account of the pathological changes in the membrana tensa to which it may ultimately give rise.

3. Routine or too frequent use of eustachian bougies or sounds is not without risks on account of the subacute reactions in the tubal mucosa to which it may give rise.

4. The first constructive effort in treatment should be an exhaustive search for possible foci of infection. As a preliminary measure, elimination of such a focus is a most positive indication.

5. Tubal disease begins in the pharyngeal end of the canal, and local treatment confined strictly to this region gives the best average results in restoring tubal function.

6. When tubal function is not reestablished by simpler means, surgical measures may prove effective.

7. Tuning fork exercises, used with care, judgment and moderation, provide a rational means of exercising both drum membrane and ossicles.

8. In most cases of advanced deafness the acoustic nerve, as well as the conducting mechanism, is involved; therefore both must be taken into account in treatment.

9. Treatment of the acoustic nerve can be considered, if at all, only from the following viewpoints: 1. Direct or local stimulation; 2, administration of drugs; 3, elimination of injurious agencies; 4, hygiene, or regulation of the patient's mode of life.

10. As there are many factors in the etiology of deafness, so is the pathology one of complexity. No inelastic, rule of thumb routine of treatment will yield the best average results.

Early Hanot's Disease

EDWARD STEINFIELD, M.D.,
and SAMUEL H. KOHLMAN, M.D.,
Philadelphia.

The classification of cases presenting enlarged cirrhotic livers associated with jaundice presents difficulties to both pathologist and clinician. This pertains particularly to certain types of cases which on clinical grounds greatly resemble Hanot's *cirrhose hypertrophique avec ictere chronique,* though under the microscope do not reveal the fine intralobular and intercellular scarring and other changes considered by pathologists as essential to the diagnosis of Hanot's disease. Though this disease had been noted as early as 1846 by Requin (1) and later described by Todd (2) and also by Hayem (3), its authoritative presentation is accredited to Hanot (4) who designated the following features as characteristic: a, youthful, usually male patient; b, chronicity and fluctuation of the jaundice; c, fever, especially in the early stages; d, painless enlargement of the liver and a fairly large spleen; e, the liver on inspection was fairly smooth or slightly granular. Under the microscope could be noted fibrous tissue perilobular and intralobular in distribution, radicular cholangeitis and pseudobiliary canaliculi in and about the periphery of the lobule. The liver cells were usually free from degenerative changes and in this way differed from sections of livers from cases of atrophic or Laennec's cirrhosis. The fibrous tissue had little tendency to contract in the degree noted in atrophic cirrhosis.

This categorical description was from time to time modified by various observers and several groups were designated especially by the French authors with reference to the degree and priority of hepatic and splenic enlargement. A comprehensive volume on the subject was issued by Lereboullet (5) in 1902 in which a large number of collected cases are grouped according to this plan. Reproductions of sections indicate in a number of instances that minor or atypical changes are sufficient in placing the case under the category of Hanot's disease. A number of English observers denied the existence of any characteristic microscopic feature in hypertrophic cirrhosis. Saundby (6) and also F. Taylor (7) stated that pseudobiliary canaliculi existed in cases of atrophic cirrhosis, whereas in some cases of Hanot's disease, it was not prominent. Cheadle (8) asserted that he had not observed a case which corresponded completely with the French descriptions.

The objection to the dogma of a distinct unvaried pathology in hypertrophic biliary cirrhosis is well supported by the recent experiments of Rous (9) and of Rous and Larimore (10). These observations indicate that the diversity of lesions in Hanot's disease is referable to differences in the duct levels at which the injurious agent is active. This contention is supported by the appearance of livers of rabbits in which intralobular cirrhosis has been produced. The case which is here reported contains many characteristic features of Hanot's disease though microscopically the lesions are of minor or early degree.

CASE REPORT

Case.—L. S., a white single girl aged twenty-two and born in the United States, was admitted with the complaint of persistent but fluctuating jaundice. No history of icterus in parents, brothers, sister nor other relatives. The patient had had measles, chickenpox and diphtheria in childhood. She had been a silk winder for eight years; did not use alcoholic beverages.

The patient had been perfectly well until two years before present observation, when she first noticed her skin had a muddy to yellowish appearance and that her urine was highly colored. She also noticed an oppression in the abdomen. With the exception of gaseous eructations, she had no marked digestive symptoms. The icterus increased slowly up to the present time. There were exacerbations of increased jaundice at times associated with feverishness. The skin itched since onset and xanthoma of both eyelids appeared about three weeks before admission.

There was no apparent derangements of hypophysis, pineal, thyroid, suprarenals nor gonads.

The station and gait were normal; no cranial nerve disturbances; deep reflexes normal; eye grounds were normal.

There were 3,530,000 red blood cells, hemoglobin 80 per cent., white blood cells 4,600; differential

blood count normal; blood platelets 250,000; no lymphadenopathy; spleen not definitely enlarged; blood Wassermann reaction, negative.

The teeth were in good condition; stomach and intestines by clinical and röntgenoscopic examinations presented no abnormalities; stools varied from normal to clay color but always gave positive reactions for hydrobilirubin, contained no ova nor parasites and were negative for occult blood. The liver was markedly enlarged particularly in the epigastrium where the lower border was about eight to ten cm. below the normal position. The left lobe was notably enlarged. Röntgenograms were negative for biliary calculi.

The kidneys were not palpable. Urine; specific gravity 1020, acid, faint trace of albumin, no sugar, no casts, a few leucocytes, highly colored but gave only faint or doubtful tests for bile pigments. Pelvic examination was not made, but no abnormality was revealed at laparotomy. There was moderate icterus with jaundiced scleræ; xanthoma of both eyelids; and wide areas of vitiligo on the abdomen.

Certain characteristics of the distribution of the bile pigments may here be emphasized. The blood plasma showed bile staining in dilutions up to 1 to 40. The plasma was dialyzed after the method of Hoover and Blankenhorn (11), but no separate yielding of the bile salts only to the dialysate could be detected. This is in accord with the type of icterus under consideration, though no particular emphasis is placed upon this finding. The urine, despite the apparent bile stained appearance, gave feeble or inconclusive reactions for bile pigments on numerous trials. The stools, though clay colored at times, always gave some reaction for hydrobilirubin.

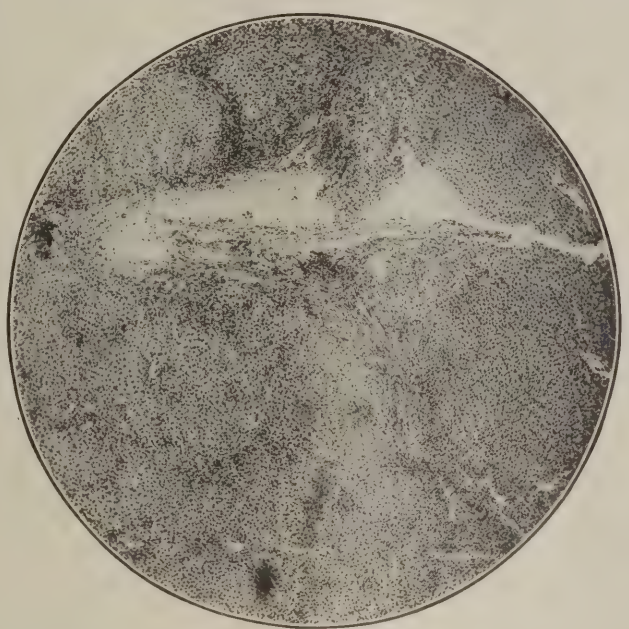

FIG. 1.—Section of liver showing perilobular and intralobular distribution of fibrous tissue.

Because of the vague possibility of hemolytic icterus despite the lack of family history and splenomegaly, the red cells were tested for undue fragility in hypotonic salt solutions. Hemolysis began at .40 per cent., and was complete at 0.30 per cent., indicating normal or slightly increased resistance. Tests for abnormalities in coagulation were done because of the possibility of operation. The figures indicate that despite the persistence of the jaundice, no abnormality could be detected. Coagulation time of blood from the vein was eight minutes; there was good retraction of the clot; bleeding time from the finger was under one minute; prothrombin time was twelve to thirteen minutes.

At operation a large slightly granular liver was noted. No evidence of biliary calculi nor other obstruction to the common bile duct could be detected. A small fragment of liver tissue was excised for examination. Upon miscrscopic study, sections showed the following characteristics: Young fibrous tissue could be noted whose coarser strands were mainly perilobular in distribution with a tendency to intralobular invasion with young fibrous tissue cells and plasma cells. The hepatic cells preserved their integrity to a great extent with here and there slight cloudy swelling. There were small areas of heaped up bile pigments in and about bile capillaries but without any evidence of pseudohypertrophy of biliary canaliculi. Radicular cholangeitis was of minor degree.

In so far as the histopathology is concerned, it could not be said that the findings resemble the categorical description of Hanot unless interpreted as an early process. The absence of splenic enlargement such as in this patient has been noted by Gilbert and Castaigne (12). After operative convalescence, the patient remained in fair health but reported exacerbations of fever and hepatic enlargement at intervals.

SUMMARY

A considerable group of cases of hepatic cirrhosis with jaundice reported in the literature conform to Hanot's clinical description of hypertrophic biliary cirrhosis though the microscopic appearance of the liver is apparently not characteristic.

The evidence of various observers supports the contention that varying histopathology is not inconsistent with Hanot's disease.

The history of a patient with the clinical picture of hypertrophic biliary cirrhosis is cited; microscopic studies show principally early perilobular fibrosis with intralobular invasion of young connective tissue cells and plasma cells.

Head Injuries*

JOHN F. X. JONES, M.D.,
and GEORGE E. PFAHLER, M.D.
Philadelphia

The following cases are reported in the order of their admission to the Misericordia Hospital during February, March and April, 1923.

EXTRADURAL AND SUBDURAL HEMORRHAGE WITH MULTIPLE COMPLICATIONS

CASE I.—Hospital No. 2294. P. S., male, aged forty, white, admitted February 17, 1923, at 9 p. m. He had been crushed beneath a trolley car, was unconscious, and in deep shock which active treatment failed to relieve. There were two brief intervals of consciousness, one at 9.30 p. m. and one at 12.30 a. m. Systolic pressure did not exceed 50. The patient died at 5.22 a. m., February 18, 1923. Autopsy at 11 a. m., February 18, 1923, by Dr. C. B. Brown: Compound fracture of the left frontal bone; depressed fracture of right temporal bone with extensive extradural, subdural and cortical hemorrhage; fracture of the nasal bones; fracture of the mandible; fracture of the right clavicle; fracture of the fourth, fifth, sixth and seventh ribs of the left side with extensive hemorrhage into the left pleura and fracture of the second, third, fourth, fifth, sixth, and seventh ribs on the right side; dislocation of the left hip, and compound fracture of the left tibia and fibula.

In this case injury to the brain played but a part in the production of the regnant condition which was shock.

BASAL COMPRESSION

CASE II.—Hospital No. 2296. J. C., male, aged fifty-six, white, was admitted on February 18, 1923, at 10 a. m. He had fallen from a ladder, was unconscious, temperature 97°, pulse 88, respirations 24. There was a large contusion in the right frontal region. Pupils were irregular and did not react to light. Temperature rose to 103°; pulse rate increased to 120, and respirations became 30. The patient did not regain consciousness, there were general convulsions, stertorous breathing, and he died about three and a half hours after admission.

Necropsy was not performed but this seems to have been a case of subtentorial compression.

EXTRADURAL AND SUBDURAL HEMORRHAGE

CASE III.—Hospital No. 2305. P. J. B., male, aged thirty-two, white, admitted February 18, 1923, at 5.30 p. m. He had been knocked down, striking the back of his head. There were no symptoms for ten hours, when he had convulsions, limited to the left side. Lumbar puncture showed cerebrospinal fluid under tension and containing blood. Right subtemporal decompression was done six hours after admission and twenty-four hours after injury. Blood was found beneath the dura; no extradural hemorrhage. The patient died five hours after operation. Autopsy, February 19, 1923, by Dr. W. S. Wadsworth: "Extradural hemorrhage in the posterior fossa, right side, occipital region with compression of the brain in this region. Also subdural hemorrhage in the temporal region on the right side—anterior fossa—fracture of the skull, extending along suture line from the external occipital protuberance down to but not through the petrous portion of the temporal bone. It is a narrow linear fracture."

The subtemporal operation relieved part only—and not the important part—of the compression.

CONCUSSION

CASE IV.—Hospital No. 2311. J. R., male, aged forty, white, admitted February 19, 1923. He had fallen from a ladder, about twenty feet, striking his head and shoulder. Was unconscious for a few minutes, reacted, vomited, and bled from the nose. Temperature was 97.8°, pulse 60, respirations 20; tenderness in left temporal region. X ray examination revealed no evidence of fracture of the skull. He was discharged in good condition on February 22, 1923.

Nearly all cases of brain injury are complicated in the beginning by a certain degree of shock. If the extent of the shock be slight and the intracranial damage limited to concussion, a patient, who on admission appears to be desperately ill, will often recover sufficiently in two or three days to be discharged from the hospital. Unfortunately, however, it is just as often impossible to tell in the first few hours after admission whether a given case is one of shock plus concussion or one of shock plus concussion and compression.

LINEAR FRACTURE OF THE SKULL WITHOUT INTRACRANIAL INJURY

CASE V.—Hospital No. 2369. F. M., male, aged ten, white, admitted February 25, 1923. He had been struck by an automobile. There was contusion of left temporal region of scalp, with ecchymosis of eyelids, abrasion of nose, and bleeding from nose. The patient was not unconscious. There were no changes in pupils, no convulsions, no paralyses. The x ray report was linear fracture in the left parieto-occipital region.

A linear fracture of the skull may be associated with grave injury to the brain, as in Case III, or it may be associated with no demonstrable intracranial damage.

LACERATION OF THE SCALP

CASE VI.—Hospital No. 2463. S. J., male, aged sixty-one, black, admitted March 8, 1923. A brick fell from an upper story and struck him upon the head. There was active hemorrhage from a deep laceration just above the left eyebrow. The patient was not unconscious and there were no symptoms of concussion of the brain. The scalp wound was sutured with drainage. Röntgenological examination

*Reported to the West Branch of the Philadelphia County Medical Society at Misericordia Hospital, November 20, 1923.

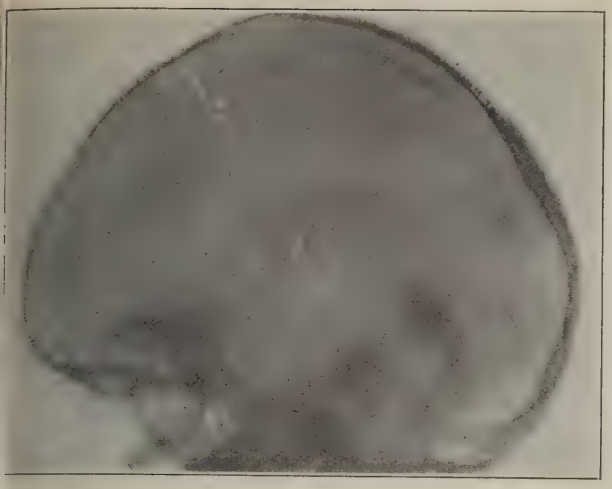

Fig. 1.—Case VIII. Master James C., aged five. Linear fracture ending in a Y extending from the vertex downward to the temporal region just posterior to the coronal suture, ending in a Y with extension backward to the right parietal region.

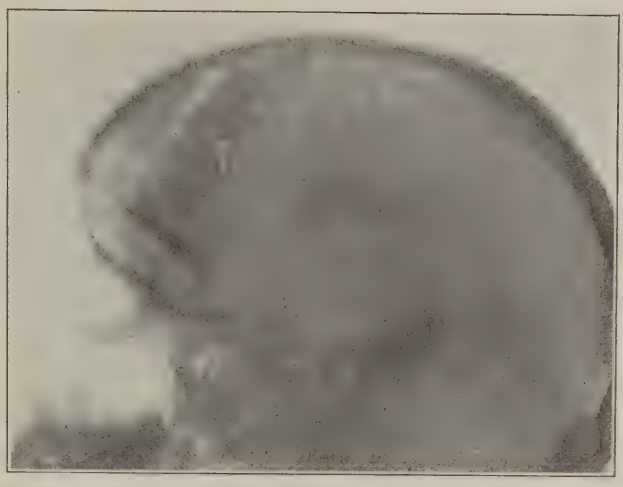

Fig. 2.—Case IX. H. J. W., aged seventeen. A comminuted depressed fracture in the right frontal region located two centimetres in front of the coronal suture and two centimeters to the right of the sagittal suture. The depressed fracture is three centimetres in diameter.

showed no evidence of fracture of the skull. The patient was referred, after three days, to the outpatient department.

The dropping of a stone, or a tile, or a piece of timber or other building material from an elevation upon the top of a workman's head often causes fracture of the vertex. This case demonstrates the well known fact that the history of the accident seldom helps in making a diagnosis of a head injury. Formerly, in cases of head injury we have attempted to elicit from the patient, his relatives, bystanders or other witnesses, on account of the manner in which the violence had been received. If the patient had tumbled or had been thrown in such a manner as to cause his head to come in contact with a hard surface or substance we inquired into the distance of the fall; whether the descent had been abrupt or interrupted, etc. If the head injury had been due to a fist, a stone, a missile, a weapon, or other instrument of trauma, we tried to learn the direction in which the force had been exerted. With no thought of minimizing the possible importance of minute details in history taking, it is merely fair to say that estimations of the extent of cranial or cerebral injury based upon the amount of violence inflicted are not reliable. A fall of but a few feet or a blow of apparently little force has caused serious intracranial hemorrhage. A fall from a great height or a severe blow has resulted in nothing more serious than a contusion of the scalp.

CONCUSSION, SUBDURAL HEMORRHAGE, AND COMPRESSION WITHOUT FRACTURE OF THE SKULL

Case VII.—Hospital No. 2503. J. S., male, aged twenty-one, white, admitted March 12, 1923. He had fallen from an automobile truck, was dazed but not unconscious and vomited. He entered the hospital five hours after the accident. Was drowsy and complained of headache, but there were no other signs or symptoms. Cerebrospinal fluid, secured by lumbar puncture, was under tension and contained blood. March 13, 1923 (about twenty-four hours

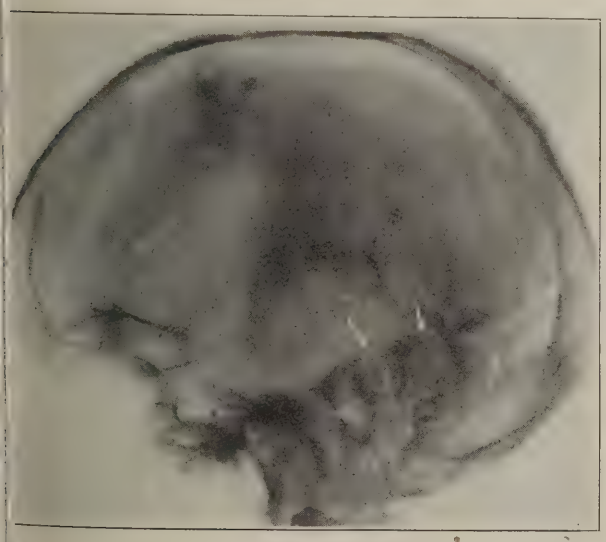

Fig. 3

Fig. 4

Figs. 3 and 4.—Case XIII. James McK., aged sixty-three. Fracture extending through the entire occipital bone beginning just posterior to the right mastoid process and extending over to the left as far as the petrous portion of the left temporal bone. The line of fracture presents a similar curve to that of the occipital suture. It is comminuted, a line of fracture extending into the left parietal bone.

after injury), subtemporal decompression of right side of brain was done and blood clots were removed from the surface of cortex. There was no extradural hemorrhage. Before operation the pulse rate was 60 and after operation it was 90. For the following six days the pulse rate varied between 44 and 48 and the patient during this time was drowsy and slept at frequent intervals. March 20, 1923, the pulse rate was 60. Dr. E. A. Strecker examined the patient, March 30, 1923, and believed his condition might be explained on the basis of severe concussion. His reaction was gradual and he was discharged April 10, 1923, in good condition. Röntgenological examination showed no evidence of fracture of skull.

An uncomplicated fracture of the skull, when the fragments are not depressed and when the line of fracture does not communicate with a wound in the scalp or mucous membrane, is of very little surgical importance. Fractures of the skull cause concern only in so far as they involve the contents of the cranium—the brain, its membranes or bloodvessels. Contrariwise, following trauma to the head, severe intracranial damage may exist without fracture of the skull.

CONCUSSION AND COMPRESSION PROBABLY PREVENTED BY DRAINAGE THROUGH THE LINES OF FRACTURE, OR BY LUMBAR PUNCTURE

CASE VIII.—Hospital No. 2516. J. C., male, aged five, white, admitted March 13, 1923. He fell out of a window and was unconscious for about ten minutes. He reacted, vomited, was drowsy, and resented being disturbed. There was contusion in left temporal region, with tenderness in right parietooccipital region near vertex. Pupils equal and reacted to light; no paralyses, no convulsions. Röntgenological examination showed an extensive fracture of the right side of the skull, as well as a fracture of the external angular process of the left frontal bone. (Fig. 1.) Twenty-five c. c. of cerebrospinal fluid removed by lumbar puncture; fluid under tension but contained no blood. On admission, temperature was 98.8°, pulse rate 140, respiration 30. About twenty-four hours after admission a large swelling appeared in the right parietooccipital region, which at first we thought was merely a hematoma. When, however, the child's drowsiness disappeared shortly after the onset of the swelling, we considered the possibility of the tumor containing cerebrospinal fluid. The patient was observed for seventeen days. On the day of discharge, temperature was 98.4°, pulse rate 96, respirations 23.

The escape of cerebrospinal fluid through the lines of fracture into the subcutaneous tissues in addition to the removal of cerebrospinal fluid by lumbar puncture probably prevented compression of the brain; or the swelling which developed in the right parietooccipital region had no subdural connection and the tension of the cerebrospinal fluid was relieved by spinal puncture alone.

CONCUSSION AND COMPOUND DEPRESSED FRACTURE

CASE IX.—Hospital No. 2585. H. J. W., male, aged seventeen, white, admitted March 21, 1923. He was struck by a street car, was stunned but not unconscious. There was laceration in the right frontal region of the scalp communicating with a depressed fracture. Pupils were equal, slightly dilated, and reacted to light. There was hemorrhage from the right ear and from the nose. Temperature 98°, pulse rate 80, respirations 20. The patient had headache and vomited. Röntgenological examination showed depressed fracture of the right frontal bone. (Fig. 2.) Scalp wound and depressed fragments were excised; dura was not opened. The patient was discharged in good condition fourteen days after admission (April 7, 1923).

Nasal or aural hemorrhage may indicate local injury strictly limited to the nose or ear. It is the presence of cerebrospinal fluid which points to fracture of the skull.

In adults, depressed fractures of the vault, with or without symptoms, should be operated upon and the depressed fragment or fragments elevated or removed. In children, when symptoms of intracranial damage exist, surgeons are united in recommending elevation or removal of the depressed fragments or excision of the hollows made in bones by obstetrical forceps. In children, when no symptoms of intracranial injury accompany these traumatic depressions, some surgeons do not operate at once, believing that the depressed bone, being young and resilient, will often return to its normal level.

FRACTURE OF THE VAULT WITHOUT SYMPTOMS OF INTRACRANIAL INJURY

CASE X.—Hospital No. 2640. W. B., male, aged three, white, admitted March 28, 1923. He had been struck by a trolley car. There were contusions in the occipital region of the scalp and abrasion of forehead and left hand, but absolutely no symptoms of intracranial damage. Skiagraphic examination (done as a matter of routine) showed fracture of the occipital bone extending from a point about three and a half cm. below the vertex downward a distance of about ten cm.—about three cm. to the left side of the midline. The child was discharged in seven days.

SIMPLE FRACTURE OF THE VAULT AND LACERATION OF THE SCALP

CASE XI.—Hospital No. 2660. M. C., female, aged forty-seven, white, admitted March 29, 1923. The patient fell downstairs, lacerating the occipital region of the scalp. No fracture of the skull was visible or palpable through the laceration. No evidence of intracranial injury. Scalp wound was excised and operative wound was sutured. Röentgenographic examination revealed a line of fracture of the right parietooccipital region which extended from a point three cm. behind and three cm. above the external auditory meatus, backward and upward a distance of six cm. There was no evidence of depression of fragments. The fracture was above the level of the scalp laceration. The patient recovered

CONCUSSION AND MULTIPLE LACERATIONS AND CONTUSIONS OF FACE AND SCALP

CASE XII.—Hospital No. 2676. E. H. W., male aged forty-five, white, admitted April 1, 1923. He had been struck by a trolley car, and was unconscious for a few minutes. There was active bleeding from multiple lacerations of scalp and face. Temperature 97°, pulse 98, respirations 26. He reacted from

shock in about three hours. Skiagraphic examination was negative for fracture of the skull.

The appearance of a patient immediately after the accident often tends to give us an exaggerated notion of the gravity of his condition. Unconscious, pale, skin moist and cold, scalp severely lacerated, he often appears to be much worse than he is. We assume, however, that every head injury is serious until we have had time enough to investigate it thoroughly. "Time enough" may mean hours or days.

If, when admitted, the patient is in shock we devote our entire attention to the treatment of shock. The patient will react from shock or die within a few hours. If he reacts from shock, we may be in doubt as to whether we are dealing with a case of pure concussion or with concussion and compression. Here our study of the clinical symptoms is fortified by the information obtained by the use of lumbar puncture, the ophthalmoscope and the röntgen rays.

FRACTURE OF THE SKULL WITHOUT SYMPTOMS OF BRAIN INJURY

CASE XIII.—Hospital No. 2697. J. McK., male, aged sixty-three, white, admitted April 3, 1923. He was struck by an autotruck, but apart from a slight abrasion in the parietooccipital region of the scalp, there were no signs or symptoms of injury. Röntgenological report: "An extensive fracture of the occipital bone involving both sides which are connected by a branch extending transversely, etc." (Figs 3 and 4.)

In this instance, the fracture of the skull did not cause as much inconvenience as the average broken nose.

CONCUSSION OF THE BRAIN AND COMPOUND FRACTURE OF THE SKULL

CASE XIV.—Hospital No. 2705. W. W., male, aged thirty-three, white, admitted April 4, 1923. Fell from a scaffold, sixty feet, striking his head and shoulder. There was laceration of scalp communicating with a fracture of the left frontal bone. The patient was conscious, pulse 60, temperature 100°, respirations 20; pupils equal and reacted to light, no paralyses, no convulsions; blood pressure 130-80. No hemorrhage except from the scalp wound. Röntgenographic report: "Linear fracture branching like a Y into the left frontal sinus and extending upward from the upper brim of the orbit a distance of about two inches." Débridement and suture. Dura not opened. Uncomplicated recovery. Discharged April 15, 1923.

Because of the danger of infection compound fractures of the skull are operated upon early. This fracture was compound via the scalp wound as well as by reason of its opening into the frontal sinus.

COMPOUND FRACTURE OF THE SKULL

CASE XV.—Hospital No. 2815. H. J., male, aged twenty-four, white, admitted April 14, 1923. He fell from a ladder, was not unconscious, and walked to the hospital where his scalp laceration, which communicated with a fracture of the skull, was dressed. He declined to be admitted to a ward and left the hospital. Next day (April 15, 1923) he returned to hospital and permitted examination by x ray, and remained in a ward only one day (until April 16, 1923) and departed, not to return. The röntgenographic examination: "Linear fracture of the left parietal bone, extending downward and forward, etc." There was no evidence of depression.

Occasionally, the victim of a head injury resists the surgeon's efforts to treat him. Whether such conduct be a manifestation of cerebral injury or the natural performance of a normally disagreeable person could be determined in a given case, we fancy, by the family physician who has been acquainted with the patient previous to the head injury.

Grateful acknowledgment is here made to Dr. C. P. O'Boyle for the skiagrams in these cases, and to Dr. Alexander E. Burke who assisted in the preparation of the report.

Extirpation of Cervical Rib Under Local Anesthesia

L. RAY ELLARS, M.D.
Louisville, Ky.
Instructor in Operative Surgery, University of Louisville, Ky., Medical Department

The seventh cervical vertebra differs from the first thoracic in having an opening through the transverse process for the transmission of the vertebral artery and vein. The anterior portion of this transverse process arises by a separate centre of ossification, and and by its abnormal growth and prolongation becomes a cervical or supernumerary rib.

There are true and false cervical ribs. The true cervical ribs have a head, neck and shaft, and articulate as do the thoracic ribs. The false ribs, which consist of only a shaft, articulate with the tip of the transverse process.

About five tenths per cent. of the x ray plates of the neck show evidence of a cervical rib, but only a small proportion (five to ten per cent.) of these give rise to trouble. They are more common in women than men, more often bilateral than unilateral, and if unilateral, occur more frequently on the right side.

The symptoms referable to cervical ribs usually present themselves under one or all of three groups, as follows: first, neurological; second, vascular, and third, tumor formation, either visable or palpable in the supraclavicular region. On account of the anatomical arrangement of the structures in the neck it is easy to understand the sequence of symptomatology. As the tip of the rib comes forward it comes in contact with the brachial plexus and usually the fibres forming the ulnar nerve, causing paresthesia, weakness, numbness, etc., especially to the little

finger, and which is more marked in the morning upon rising. The motor functions of this nerve are next involved, causing a loss of the finer movements of the hand, such as are required in sewing, writing, and piano playing. The next structure pressed upon is the subclavian artery, causing the various vascular phenomena, such as lessening of the pulse pressure in the radial artery on the affected side, sensation of coldness after long use, and slowness in the return of color to the skin after placing the hand in a basin of cold water. The rib pushing the artery upward often causes a pulsation in the supraclavicular region, with at times (twenty per cent.) tumor formation, exhibiting a thrill and leading to the erroneous diagnosis of aneurysm. The rib now in its growth comes in contact with the scalenus anticus muscle, which structure separates the subclavian artery from the subclavian vein. Venous changes, such as congestion and edema, are therefore never present. Verification of the diagnosis of a cervical rib is made by the x ray.

Fig. 1.—True cervical rib, having distinct articulation with the transverse process of the seventh cervical vertebra, and extending in a curved manner downward and forward about three and a half inches.

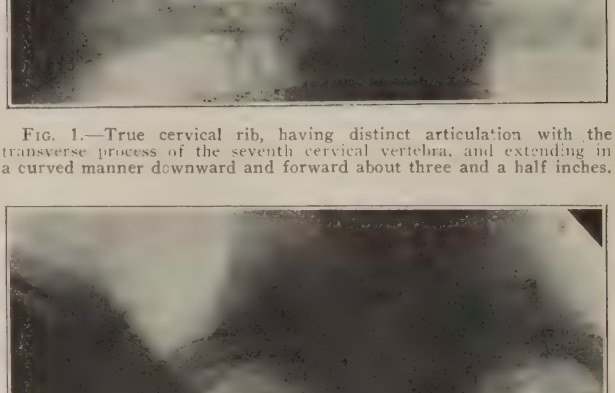

Fig. 2.—End results; all symptoms relieved entirely.

The treatment is entirely surgical, and consists in removing the rib with its periosteum, so it will not regenerate, through an incision parallel to the anterior border of the trapezius and scalenus medius muscles.

Case I.—Male, white, aged twenty-four years, with a negative history except that for several years he had been a morphine habitue, and only prior to operation had taken the cure. He complained of numbness and weakness in the right arm and forearm, a condition which began nine years ago with paresthesia along the structures supplied by the ulnar nerve, especially the little finger. He was unable to hold a pencil in writing for any length of time. These symptoms were always more marked in the morning, so that the patient dreaded to see the morning approach, for fear that his right arm would be completely paralyzed. The symptoms were always more exaggerated after prolonged use of the arm.

Physical examination disclosed a fullness in the supraclavicular fossa, with slight pulsation on palpation. There existed a distinct difference in pulse pressure to palpation of the two radial arteries, the right being distinctly weaker. The patient placing both hands simultaneously into a basin of cold water, it was noted that the natural color returned to the left hand in two minutes, while in the right it required four minutes. The physical examination was otherwise negative, except that the heart showed a marked hypertrophy, the apex beat being in the seventh interspace at the nipple line. On auscultation a harsh murmur was found, which was both systolic and diastolic in time.

The clinical diagnosis was right cervical rib. X ray examination disclosed a true cervical rib, having a distinct articulation with the transverse process of the seventh cervical vertebra, and extending in a curved manner downward and forward about three and a half inches (Fig. 1).

Operation.—The skin was anesthetized with a one per cent. apothesine solution by using a fine needle on a line parallel with the anterior border of the scalenus medius muscle, curving the base slightly toward the clavicle. The deeper structures were next infiltrated with the same solution, and by blunt dissection the scalenus anticus was freed high up, on a level with the upper margin of the seventh cervical rib. By continuing the blunt dissection we came down upon the neck of the cervical rib. The structures around the rib were next infiltrated with the apothesine solution, and then by means of a periosteotome they were pushed forward, exposing the neck of the rib. A curved depressor was then passed beneath the neck of the rib to protect the pleura, and by means of pointed bone cutters the neck of the rib was severed. The shaft was then grasped with bone forceps and by blunt dissection removed in its entirety with the overlying periosteum.

At only one point in the course of the operation was the pain of any consequence, and that was when the tissues were dissected from the shaft of the rib after it had been cut. At this point the patient was given a small amount of ether, just enough for the psychic effect, and the rib was evulsed before he had even reached the primary stage of anesthesia. The mask was then removed and the remainder of the operation completed painlessly. Because of the fact that the patient had been a morphine habitue, no preliminary sedative was administered, anesthesia being produced by apothesine alone. The radiogram in Fig. 2 shows the end results. All symptoms were relieved entirely.

Relation of Cholesterol Metabolism to Surgical Problems of Cholelithiasis and Infection of the Biliary Apparatus*

ABRAHAM O. WILENSKY, M.D.
New York.

Cholesterol is a lipoid body. The metabolism of cholesterol is intimately bound up in the function of the liver. The available evidence, both from experimental animal work and from comparative physiological sources, seems to show conclusively that the cholesterol bodies are primarily derived from the diet and are absorbed from the intestinal tract into the blood stream. On reaching the confines of the liver, the excess of the quantity, which should normally be present in the blood stream, is taken up, is excreted by the liver cells and furnishes an important constituent of the bile. The latter, on reaching the intestinal tract, forms an additional source to the food supply from which cholesterol is also absorbed into the blood. A complete circuit is thus established. It follows from these facts and from many studies made by various workers in different laboratories that: 1, The cholesterol content of the blood of various animals and of different human races depends upon the cholesterol (lipoid) content of the food. 2, The cholesterol content of the bile is dependent upon the cholesterol content of the blood. 3, A marked increase of the cholesterol content of the blood will cause a marked increase of the cholesterol content of the bile. The converse of this is also true.

It has also been empirically established that: 1, The cholesterol content of the blood is lowered by the presence of fever (infection). 2, The cholesterol content of the blood is increased: a, by the presence of other diseased conditions especially atherosclerosis, diabetes and nephritis; b, during pregnancy and the postpartum period; c, by the presence of obstruction in the common bile duct. If the obstruction is not absolute however, as indicated by the degree of the accompanying jaundice, the cholesterol content of the blood may not be increased.

In normal human bile the cholesterol content varies from twenty to eighty mg. to 100 c. c. In normal human blood the cholesterol content varies approximately from 150 to 180 mg. to 100 c. c.

Theories have been developed in regard to gallstone formation. The first of these, sponsored by Naunyn, assumes similarities in the pathological processes of catarrhal inflammations of all mucous membranes, attempts to show that an increased formation of cholesterol accompanies all of these inflammatory conditions, and finds in this conception the chief underlying factor in gallstone formation. The presence of bacteria in the centres of some stones and in the gallbladder wall lends support to this hypothesis.

The facts which I have previously summarized regarding the metabolism of the cholesterol bodies and their physiological and pathological variations form the main support of the theory of an opposing group. Aschoff and Bacmeister were the first to point out that, morphologically, the gallbladders in which pure cholesterol stones are found show practically no inflammatory reaction.

As one meets these conditions on the operating table the various pathological pictures which one encounters are essentially the following:

1. Gallbladders of normal gross and histological structure containing usually a thin bile together with a variable number of stones; bacteriologically, these are frequently sterile. Such gallbladders may be of normal size, or more or less dilated. Stones sometimes coexist in some part of the terminal duct system.

2. Hydrops of the gallbladder due to the presence of a single, large stone impacted, more or less completely, in the neck of the gallbladder. The contained bile is watery and is most frequently sterile.

3. Gallbladders in which infection has occurred, containing a thin pus, or more rarely a thick, creamy pus with stones. The walls of the gallbladder are thickened and edematous and the mucous membrane is very frequently gangrenous. Abscesses may be present in the wall of the gallbladder, between it and the liver bed, or, more rarely, in the substance of the liver a short distance away. Various grades of hepatitis are always present. The stones contained in the gallbladder may be numerous indicating that conditions correspond to the first group plus added infection; or only a single stone is present indicating that a hydrops has become secondarily infected. In all the cystic duct becomes shut off. Stones may coexist in any of the large ducts.

4. Gallbladders which have shrunken to less than their normal size, and the walls of which show a chronic productive inflammation, frequently with areas in which evidence of a more recent inflammatory reaction is discernible. There is a variable amount of pericholecystitis. The contents of the gallbladder may consist of stones and bile, which may or may not be purulent; or thick emulsions of cholesterol containing fragmentary stones are present. When the cystic duct is open the condition represents the end results of groups 1 and 2; when the duct is obliterated it is the end result of group 3.

5. Inflammatory gallbladders varying from catarrhal to suppurative types of inflammation but without the formation of stones.

6. Gallbladders corresponding in structure to those in group 4 but without the formation of stones. These represent the end results of the cases in group 5.

The various forms of calculi which one encounters are the following:

1. Practically pure cholesterol stones containing from seventy-five to ninety-eight per cent. of cholesterin. According to Wilensky and Rothschild these correspond to precipitation stones according to the theory of Aschoff and Bacmeister.

*From the Mount Sinai Hospital, New York. Read by invitation at a regular meeting of the Eastern Medical Society, October 13, 1922.

2. Stones containing from seventy-five to forty per cent. of cholesterin. These stones may have resulted secondarily from those in the first group and are probably due to some extraneous superadded factor.

3. Small faceted stones with nuclei of bile salts and some cholesterin and outer shell consisting almost entirely of cholesterin. These calculi are of an infectious origin and contain from five to forty per cent. of cholesterin.

4. Bilirubin calcium stones. These stones are rarely found in the gallbladder, much more frequently in the intrahepatic ducts and occasionally in the common bile duct. Practically all of the stones found in cases of intrahepatic cholelithiasis are of this nature. These stones usually have an infectious origin. The cholangitis which usually coexists can be considered most commonly as a primary factor.

The laboratory facts which I have just outlined seem to indicate that in clinical medicine both the theory of Naunyn—infection—and the theory of Aschoff and Bacmeister—disturbed metabolism—are equally operative, and that no one occurs to the total exclusion of the other. In certain of the cases the diseased condition of the bile passages are initiated by a bacterial infection. It may remain a purely infective process without stone formation, or it may cause changes in the excreted bile with subsequent stone formation. In other cases there may be a primary disturbance in the cholesterol metabolism leading to a precipitation of stones and finding its inception most frequently during the physiological period of pregnancy.

For any individual case the available knowledge indicates that the biological sequence of events may be one of three:

1. The pure infections. The element of the metabolic disturbance does not enter here unless there is a complicating obstruction of the common duct. The affection begins as a catarrhal cholecystitis, or as a frankly suppurative process and, if no intervention ensue, subsides more or less incompletely; when repeated recrudescences of infection are permitted the lesion terminates in the contracted and shrunken gallbladders previously described.

2. The cases that are due to disturbances of metabolism. For the cases in this group pregnancy plays the most important rôle. As indicated abundantly in clinical medicine, pregnancy is the most frequent precursor of cholelithiasis. During the entire period of pregnancy there is a physiological increase in the cholesterol content of blood and bile and the hypercholesterolemia continues for a variable time after the evacuation of the uterus. There are normal compensatory mechanisms which, under ordinary circumstances, take care properly of this excess and prevent any untoward phenomena from occurring. However, the hypercholesterolemia of pregnancy may reach to such a degree as to make futile the normal compensatory mechanism; then the supersaturation of bile with cholesterol bodies is reduced to the normal by a precipitation of stones in some portion of the biliary apparatus, almost always the gallbladder. If no further hypercholesterolemic crisis occurs, a quiescent period follows and many times this continues without symptoms for the remainder of that particular person's life; or the patients have symptoms (gallstone colic) which are due to the mechanical effects of stones acting as foreign bodies. Repetitions, however, of this physiological increase of cholesterol bodies (pregnancy) are likely to occur —perhaps frequently repeated at regular or irregular intervals, so that there will be new hypercholesterolemic crises with their corresponding production of calculi. This explains the finding of stones in a given gallbladder of various sizes and chemical compositions and apparently of various ages. In these metabolic disturbances the bile passages undergo changes mechanically, owing to the presence of stones acting as foreign bodies.

3. Combinations of infection and disturbed metabolism occur either simultaneously or alternately and with different degrees of severity. Depending on the factor which is paramount, on the intensity of the latter's manifestations, on the stage of the process, or on the presence or absence of the many complicating factors, which now become numerous, the pathological and clinical picture shows the wide variations previously indicated.

It must be conceded that in any given case the diagnostic value of any determination of the cholesterol content of the blood is a variable and dubious one. Wilensky and Rothschild have summarized those gallbladder conditions in which the cholesterol content of the blood can be normal as follows:

1. In the presence of stones in a normal gallbladder, without common duct obstruction and with or without high temperatures.

2. In the presence of a chronically inflamed gallbladder containing stones without common duct obstruction and with or without high temperatures.

3. In the presence of any of these conditions with incomplete obstruction of the common bile duct.

4. In the presence of an empyema of the gallbladder, with or without stones, with fever, and with no obstruction in the common bile duct.

5. In conditions as in the preceding division (4) with partial or complete obstruction in the common bile duct.

The finding of a hypercholesterolemic condition, while usually pointing to some disturbance of the cholesterol metabolism and in the bile passages, is always subject to correction in the presence of any of those complicating factors (atherosclerosis, diabetes, nephritis), mentioned in the earlier part of this communication, which, by themselves, are capable of increasing the cholesterol content of the blood. And when this correction is to be made it becomes difficult, if not impossible, to decide whether the entire excess of the cholesterol content of the blood above the normal is due wholly, or only in part, to these complicating factors. The situation becomes all the more complex when it is known that it is possible to obtain hypercholesterolemic figures in other diseased conditions.

The occurrence of a hypercholesterolemia can be used as a diagnostic factor in only one instance. When a distinction must be made between the jaundice due to cirrhosis of the liver and the jaundice due to common duct obstruction the finding of a hypercholesterolemic condition indicates that obstruction is present. Cirrhotic conditions uniformly give low figures for the cholesterol content of the blood.

A proper interpretation of any blood finding is

only possible after knowledge is obtained of the actual anatomical conditions present.

It is regrettable that for the ordinary case of gallbladder disease these facts and studies in regard to the relationship of the cholesterol metabolism to the demonstrable pathology have furnished or added no decisive aid of a therapeutic nature. One can influence the cholesterol content of the blood and bile by dietary means, but, unfortunately, the pathological changes in the gallbladder, bile passages, liver and associated organs are of a mechanical nature and are only correctible by surgical means. What has surgery to offer?

Cholecystectomy fulfills a double purpose:

1. It removes a local focus of infection. When the latter is strictly limited to the gallbladder this can be done completely and the effect is a permanent one. In the cases, however, in which the focus of infection has spread beyond the gallbladder itself, either into the ducts or, perhaps, into the liver substance, surgical removal of the entire infected area is not feasible or possible, and a complete cure follows only when efficient drainage is carried out.

2. It removes the biliary reservoir with its contained stones and stagnated, infected and changed bile. The latter represents part of the endproducts of any disturbance of metabolism which had antedated the operation; there is no effect upon the metabolic activities themselves. In order to obtain any effect upon the latter it is necessary to institute bile drainage either by leaving the stump of the cystic duct open (an inefficient method) or by making an additional opening into the common or hepatic ducts (a most efficient method).

Cholecystostomy accomplishes the following objects:

1. It affords a surgical method, inferior to cholecystectomy, for draining the infected area. This does not presuppose that the focus of infection in the gallbladder has been removed and apparent healing may take place before this source of infection has completely disappeared. Recrudescences of infection may therefore be expected and do actually occur; they form one of the important causes for the recurrence of symptoms after operation.

2. Bile drainage is a necessary concomitant and sequel of cholecystostomy; and the method permits a better removal of the endproducts of disturbances of metabolism. The effects of bile drainage have been summarized by Wilensky and Rothschild as follows: A. With common duct drainage the system is rapidly depleted of the accumulated products of an abnormal metabolism. B. Gallbladder drainage does not accomplish this extreme effect unless there be a concomitant obstruction in the common bile duct. C. These effects are obtained when the operation is properly done and all obstructions removed.

The good effect of bile drainage upon a disordered metabolism is probably in the nature of a recuperative process, founded upon the removal of abnormal amounts of excretory products; this seems to have marked similarities to the phenomena of fatigue and rest in muscle tissue associated with the accumulation and discharge of excretory bodies produced by cellular activity.

To these effects may be added the following: D. Bile drainage is an invaluable adjuvant in the control of any focus of infection in the intrahepatic biliary apparatus. For this purpose it is necessary to continue the drainage for many months' time.

The continued loss of bile from a biliary fistula has a deleterious effect upon the animal organism. The symptoms that are likely to appear include, a, disturbances of digestion frequently associated with vomiting; b, constipation of varying degrees due to an absence of bile from the intestinal tract; c, depreciation in the general condition of the patient conducive to a lessened general resistance to any kind of mechanical (operative) or bacterial trauma. These effects may be prevented by collecting the escaping bile and feeding it to the patient by the stomach tube. As regards the cholesterol content of blood and bile, our studies (Wilensky and Rothschild) have shown that, 1, In uncomplicated cases the figures do not change appreciably and the variations are within the normal range. This refers especially to cases without bile drainage and to those in which previous to operation the blood content of cholesterol was within the normal range. 2, When obstruction is present before operation the complete removal of this is followed by a fall from the preoperative hypercholesterolemia, the figures reaching a normal level fairly promptly. 3, If the preoperative figure has been low because of the presence of much fever (infection) the drop of temperature following the operation may be accompanied by a rise in the cholesterol content of the blood to the normal level. 4, When the postoperative decrease of the cholesterol content of the blood has been large and there had been no antecedent obstruction the diminution is due to a lipoid free diet.

It appears then from all of these facts that the choice of the proper operation efficiently carried out, combined with the intelligent use of bile drainage, restores the individual patient to that previous condition of life and health when no hypercholesterolemic crisis had yet occurred and when no bacterial infection of the bile passages had yet taken place. When the primary factor at fault is a disturbance of the cholesterol metabolism the essential thing to be accomplished is an adequate and prolonged bile drainage in order to deplete the body of a supersaturation with cholesterol. When the primary factor at fault is infection the removal, or adequate drainage of the infected area is indicated. When, as happens frequently, perhaps most frequently, both of these causative factors are working together, both of these indications must be met in order to obtain the most satisfactory result. The cause of any disturbance of metabolism is influenced in no way. And any repetition of the cause for the disturbance—and I speak especially of pregnancy—is always fraught with the danger that a new hypercholesterolemic condition may follow.

In cases of recurring symptoms after primary gallbladder operations sufficient to warrant secondary explorations a variety of lesions are found. The most frequently demonstrated include, a, adhesions of various kinds; b, stones in the gallbladder or ducts or in both; c, persistence of infection; d, biliary fistulæ; e, common duct obstructions of various kinds including malignancies; and, f, chronic pancreatitis. In some of the cases more than one of the conditions enumerated are found.

Little attention has, however, been placed upon the small number of cases with recurring symptoms in which the underlying disturbance of metabolism continues or recrudesces because of insufficient drainage or because of other reasons over which we have no control or about which we have no knowledge. The symptoms due to this cause may be mild, or most severe, may consist of mild indefinite abdominal pain, or may be marked by attacks of violent pain with jaundice, vomiting and fever; and all of these show on examination a hypercholesterolemia. All of these except, perhaps, the most severe, can be controlled by rigid attention to the diet; this should have excluded from it all lipoid bodies. For the most severe, abdominal exploration and bile drainage are indicated.

Alcohol Taxation and Delirium Tremens in Denmark*

KNUD H. KRABBE, M.D.
Copenhagen

As a rule it is difficult to compile statistics dealing with chronic alcoholism. There exist two reasons for this. On one hand there are no hard and fast lines within which chronic alcoholism can be defined. On the other there is scarcely any field of medicine in which purely personal points of view are so dominant as in the judgment of what must and must not be ascribed to chronic alcoholism.

However, there is one disease consequent to chronic alcoholism in which these difficulties are not so dominant, and that is, delirium tremens. This disease occurs seldom in atypical forms, in which the diagnosis is difficult. Individual opinions play scarcely any rôle in the judgment. The actual number of cases of delirium may not be an index to the number of cases of chronic alcoholism, but a study of the great fluctuations in the number of cases of delirium tremens should afford a rough guide to the fluctuations of the incidence of chronic alcoholism. Taking into consideration the problem of such fluctuations I have examined a number of cases of delirium tremens treated in the Kommunehospital of Copenhagen during the last twenty years.

Copenhagen, which has a population of about half a million, has several municipal hospitals, but only one department for mental diseases. All cases of delirium tremens, which the physicians in Copenhagen want to send to the hospital, are collected in this department, and it must be said that nearly every case of delirium is sent and admitted to the hospital. We have counted the cases according to the summaries of the reports for every month. In these cases are included both the uncomplicated cases and those which are complicated by pneumonia and other diseases, and the abortive cases. The figures are:

Year	Men	Women	Total	Year	Men	Women	Total
1903	325	18	343	1913	248	19	267
1904	240	22	262	1914	246	9	255
1905	296	30	326	1915	239	10	249
1906	340	16	356	1916	293	17	310
1907	430	17	447	1917	78	4	82
1908	388	14	402	1918	9	..	9
1909	316	22	338	1919	11	..	11
1910	319	17	336	1920	18	..	18
1911	317	28	345	1921	26	..	26
1912	239	22	261	1922	11	..	11

If we consider these cases we shall see that they may be divided into two groups: In the period of 1903-1916 the number of cases of delirium tremens ranged from a minimum of 249 in 1915 to a maximum of 447 in 1907, the average for this period being 321. In the period of 1918-1922 the number of these cases ranged from a minimum of 9 in 1918 to a maximum of 26 in 1921, the average being 15 cases every year (the average error is insignificant in these cases). Such a decrease, corresponding to a diminishing of the cases about ninety-five per cent. can not be a casual occurrence. What may be the cause of this enormous decrease?

There was no change in the staff of the hospitals in 1917. In 1919 a new chief physician was appointed for this department, and while such a change might have had some influence on the diagnosis in many cases, it is highly improbable that it would have any influence on the diagnosis of delirium tremens which is so characteristic and typical. The most natural thing would be to consider the decrease in relation to the legislation on alcohol in the year 1917 (partly caused by the German submarine war).

Before mentioning this legislation we shall see in what manner the cases are represented in 1917.

	Total		Total
January	31	July	2
February	19	August	4
March	16	September	0
April	4	October	0
May	3	November	2
June	1	December	0

[1]In March there was one case in a woman, in April one case, in May two cases; all other cases were in men.

It will be seen that the great decrease in 1917 began at the transition from March to April.

We will now discuss the acts which appeared in 1917 concerning the production and sale of alcohol.

On February 27, 1917, a regulation from the Minister of the Interior prohibited the sale and serving of alcoholic drinks. This absolute prohibition lasted only a month; on March 23, 1917, this law on prohibition was repealed, and since that time we have had no prohibition of alcohol in Denmark.

In the same ministerial notice from March 23d maximal prices on aquavit, whiskey and other strong spirits were fixed according to an act of March 17, 1917, to which was added an additional tax on spirit so that the price in retail trade was doubled. The price of aquavit, which before the war had been about seventy ore (twenty cents) a bottle, was now increased to more than two kroner (sixty cents). Finally, December 21, 1917, a law was passed providing for the taxation of spirits, after which the price was increased to about ten kroner (three dollars).

*From the department for nervous and mental diseases in the Kommunehospital in Copenhagen.

The legislation during 1917 concerning alcohol seems not to have had any considerable influence on alcoholism apart from the enormous taxation of the strong spirits. Only on two other points has the legislation concerning alcohol some interest. As there was not sufficient barley it was decided that only eighty per cent. of the amount of barley which had been used in 1916 must be used for brewing in 1917 and succeeding years and the breweries which before brewed Bavarian beer partly with three per cent. partly with four per cent. alcohol could brew only with three per cent. Undoubtedly this moderate restriction has not had any influence in comparison with the enormous taxation on the strong spirit.

Another restriction concerning aquavit would seem to have been more significant, in that it was decided in a ministerial notice of March 6th, that there must be distilled only one quarter of the amount of aquavit that had been distilled before. But this restriction has had no influence, because the high taxation of aquavit has produced such a diminishing of the sale of aquavit that the population has not requested the permitted twenty-five per cent. After 1917 anybody in Denmark at any time could buy a bottle of aquavit if he would pay three dollars for it. My personal impression has confirmed the significance of the high taxes. When I asked hospital patients, who had been drunkards before, what was the cause of their diminishing use of spirits, the answer has constantly been, because aquavit has been so expensive.

It will be seen from the figures that from the year 1917 the cases of delirium have reacted very promptly to the temporary prohibition. But it will also be seen that there has not appeared any reaction since the annulling of prohibition. Further, the figures indicate that the slight increase in the number of cases from 1918 to 1921 is compensated by a decrease in 1922.

What conclusions may be drawn from these figures? We can conclude that a good principle has been followed in Denmark concerning alcohol legislation. It has been possible, without prohibition, merely by the high taxation of strong spirits, to diminish chronic alcoholism in such degree that ninety-five per cent. of the cases of delirium tremens have disappeared.

It is very possible that absolute prohibition would have had the same effect, although the impression from the neighboring countries of Denmark, viz., Norway and Finland, which have alcohol prohibition, does not seem to be so good. At any rate, it seems to be a fact that the phenomena of prescriptions for whiskey from the physicians and homebrewing are very rare in Denmark.

Education Stoops to Conquer

S. DANIEL HOUSE
Los Angeles

How much realism is the modern classroom capable of? That is *the* question for educators—including parents and priests, editors and philosophers of ethics. We undoubtedly fail to accredit children with the shrewdness (shall we call it wisdom?) they actually possess. In relation to "worldly" matters they are wise beyond their years. Is it not so? Children of fourteen, bred in a tenemented environment, habitués of the moving pictures and the musical comedy and the vaudeville and the melodrama, night wanderers amid a varied crude life of suggestion and excitation, are not in truth what fond parents thoughtlessly call innocent and unsophisticated. These alert youngsters understand many of those private details of our hectic life which adults, in their blindness, assume to be the prerogative and property of grownups alone. To this the more observant among our teachers will testify. We must, in behalf of scientific truth and of human welfare, courageously reconsider our familiar attitudes toward children and the Age of Innocence. No duty of educators can be more urgent than such a realistic study of child life as will illuminate the inner life of the young.

No problem in the history of education can be more significant than this: the sincere pursuit of truth, the whole truth, concerning childhood. There are too many evilly wise young children in our midst for us longer to dare to blink the terrifically meaningful facts brought to life by the specialists in sex and the psychopathologists. We must conquer our squeamishness and face the facts. Our school education, to its eternal discredit be it said, has not bothered its feebly virtuous head about the profound problem of sexual truth and candor.

The reasonable, the common sense thing to do is to fetch into the classroom all those blind alley experiences which perturb and perplex and terrify our youthful ones, experiences and imaginings and strange surmises which influence the mind (for good or evil) for the remainder of life. If the schoolroom cannot invent means and methods whereby the miscellaneous vulgarization of the gutter life—to employ a harshly graphic phrase—may be sifted and purged and sublimated and made beautifully valuable for youth's everyday life, the miscarriage of education will be woefully complete. Against that distressful time, what sane measures of prevention may we inaugurate? The first sagacious step toward purification of gutter experience is the frank recognition of the tense vitality, the gripping interest of the thing we would refashion.

What are the juvenile possibilities of selfrealization in a frank world of selfanalysis and of socalled early maturity? May it not be wise for us to encourage children to speak their subconscious minds, without apology or shame or fear, on the vital street corner themes of sweethearting, sex yearning, dreams (day dreams and dreams at dawn), the life of peeps and secrecies and strange familiarities, the romance of gang morality? The psychosexuality of children arrived at puberty must

become a subject of deep informal study in the classroom. And why not? Group analysis, under educational guidance, can effect a transformation of folly into wisdom such as no other guidance can confer. Honest introspection dissipates dirty frivolity and prepares the mind for honor. Not a panacea, but a wise first aid! What worldly wise insights are the young capable of, in our swift and penetrating times, without excessive injury to their physical or intellectual integrity? The modern classroom is not sufficiently experimental (the brave efforts of Huxley and Spencer notwithstanding). It lacks the analytical mode of approach. It lacks the Socratic inspiration. Intellectual honesty is not its conscious goal! Pretense and the solaces of hypocrisy are its abiding sources of high endeavor. The average pedagogue is incredibly timid, a feeble and inadequate vessel of light, a battered fragment of reality. Selfrealization has been in his (and her) life nothing more creative than a traditional symbol of idealism beyond attainment for the common run.

What shattering irony in Dr. Montessori's discovery that the methods she had found successful in dealing with defectives, like idiots, were, most of them, quite applicable to normal children—for example, to the pupils of our ordinary public schools—and that these ordinary schools needed just such a transformation in method and spirit as she had achieved in her own experimental poor school! The profound influence upon modern educational ideals and realizations of medical minded educators is deserving of a large commemorative volume in itself. To enumerate only a great few: John Locke, Rodriguez Pereira, Edouard Seguin, William James, Boris Sidis, Maria Montessori, Havelock Ellis, G. Stanley Hall, Sigmund Freud. The modern medical theory of education was stated and finely illustrated in John Locke's attitude toward educables: "Locke, fortunate in combining the experience of a physician with that of a teacher, hit on the truth, almost by accident, that there can be no true education which does not adapt itself to the nature of the learner." A revolutionary conception in modern education! Continues Boyd, the distinguished English writer on education, "All through his discussion of education he thinks of the pupils as a doctor thinks of his patients—as individual cases to be diagnosed separately and to be dealt with by the methods best suited for their special temper and condition." Profound doctrine, this, with which the vast majority of pedagogues have not yet caught up. That the insights of the medical psychologist should be endowed with a momentous significance for the philosophy of education (and the education of philosophers) need surprise no one even slightly acquainted with the deep probing researches of psychoanalysis and the discoveries of the psychopathology of everyday life.

Herbert Spencer knew the basal importance of the physiology of education, and his pellucid book on *Education* still remains a classic exposition of a sound scientific practice. Today we know the overwhelming importance of the psychopathology of education as process and as ideal. To the sage doctor we humbly look for the sanest educational guidance. For education at its profoundest is a psychotherapeutic art. In sober truth, all of us in our aspirational moments dream of education as the panacea. It might well have been only yesterday that Edouard Seguin wrote his famous criticism of school education, so vastly applicable to the contemporary situation does its prove itself to be. "In the people's schools, thousands of pupils are herded together as in so many barracks, without the least thought being given to their diverse physical aptitudes, or their varied physiological needs, or their different mental dispositions; and day by day four or five rations of intellectual provender are served out to them indiscriminately. Memory is the one faculty called into play; all the other faculties of body and soul are neglected, and their organs are allowed to become atrophied and useless."

In his passionate denunciation of current educational ideas and practices, Professor Boris Sidis admonishes us that "our educators are narrow-minded pedants. They are occupied with the dry bones of textbooks, the sawdust of pedagogics, and the would be scientific experiments of educational psychology." His book, *Philistine and Genius,* is a masterpiece of invective and of critical commentary. In his view there is no redeeming aspect of our school system to which the lover of wisdom can award the smallest merit. He says quite bluntly that our socalled educators "are ignorant of the really vital problems of human interests, a knowledge of which goes to make the truly educated man." (Or woman!) The truth about life—what has education (that congenital hypocrite, pandering so faithfully to the pursuers of profit and prestige) ever revealed concerning it? History is used as apologetics, as a device for spreading distorted propaganda. English is used as a medium for the egotistic inculcation of race pride. Economics is employed as a powerful prop of the reactionary *status quo.* The educational system of our land is nothing more than the advertising and secretarial departments of Big Business. All the vital subjects of youthful inquiry and concern are perverted to the chauvinist uses of an upper class educational bureaucracy. And the truth about life—what has our education done to it?

Every honest fellow knows that no sooner out of school than he has to unlearn the lies and half truths and pseudo truths and disingenuous little truths plastered over his uncritical mentality in the days of his credulity. As we reflect upon the tragic miscarriage of education, we can the better apprehend the nature and quality of the humanist task confronting us if we recall the wise observation of Dr. Ernest Jones, illuminating expositor of psychoanalysis: "We are beginning to see man not as the smooth, selfacting agent he pretends to be, but as he really is—a creature only dimly conscious of the various influences that mold his thought and action *and blindly resisting with all the means at his command the forces that are making for a higher and fuller consciousness.*" (My italics.)

In the light of the new psychology and under the guidance of the new philosophy of education, the query becomes increasingly pertinent: How much realism is the modern classroom capable of?

Practical Therapeutics

TREATMENT OF ENDARTERITIS OBLITERANS SYPHILITICA WITH INTRAVENOUS INJECTION OF COMMINUTED MERCURY

FRANK G. YOUNG, M.D.

Brooklyn, N. Y.

STATUS OF ENDARTERITIS

Endarteritis obliterans has received scant attention in American medical literature. This disease has long been a *bête noire* to practitioners and is generally conceded to be refractory and intractable to treatment in the extreme. It is probable that the comparative rarity of the disease, coupled with the general impression of its inevitably bad prognosis, has deterred investigators from attempting to solve its complexities.

The French (1) have long recognized the rôle of syphilis in the etiology of endarteritis obliterans, but for some reason that is not apparent no one seems to have given it much study since the development of the Wassermann reaction has simplified the detection of syphilis. From the results published herewith a thoroughgoing investigation of endarteritis obliterans is indicated, such investigation being guided by the probability that the disease takes its origin from a luetic taint.

DIFFERENTIAL DIAGNOSIS

Much confusion has taken place in differentiating between endarteritis obliterans, Weir Mitchell's erythromelalgia, Raynaud's disease and thromboangiitis obliterans or Buerger's disease. True endarteritis obliterans, as described in this case, has been defined as possessing the essential characteristic of "a progressive thickening of the tunica intima without atheromatous degeneration" (2).

An excellent historical account of the disease, together with several interesting case reports, has been given by Eising (3) and need not be recapitulated here. Unfortunately, his work was done before the development of the Wassermann reaction and the probable luetic origin of the cases he describes was not confirmed.

INCIDENCE

An interesting fact mentioned by a number of writers (4, 5, 6) is that Russian Jews seem to be preponderately affected by endarteritis obliterans, Raynaud's disease and Buerger's disease. On account of the frequency of neuroses among this class of patients, they possess a high susceptibility to neurosyphilis, and endarteritis obliterans syphilitica should therefore be considered as being a manifestation of neurosyphilis as well as a vascular form of lues. In fact, the progress of endarteritis obliterans in affected individuals may be exacerbated by a vasoconstrictor manifestation of neurosyphilis that accelerates the closure of the arteries from their thickened intima. This hypothesis is suggested by the following case:

CASE.—C. F., male, aged fifty-one, photographer, came to me on February 18th. I diagnosed the case as endarteritis obliterans and sent the patient to the Cornell Clinic for confirmation. Their reply confirmed my diagnosis of endarteritis obliterans of luetic origin, especially of the legs, and they advised immediate removal of both legs. However, there was no gangrenous condition, only a simple blanching of the tissues due to lack of circulation and the severe pain, and I decided to postpone amputation. Spinal fluid Wassermann was four plus; blood Wassermann negative.

This decision was reached, not only on account of the condition of the patient's limb just described, but also because his spinal fluid Wassermann was found to be four plus, although his blood Wassermann was negative. This apparently anomalous condition was due to the fact that the patient had for a long time previously been treated for syphilis by other physicians, with mixed arsenic and mercury therapy, bringing about the situation frequently encountered in neurosyphilis whereby the blood quite readily reaches a negative Wassermann reaction during antiluetic therapy, while the spinal fluid remains consistently positive, due to the extreme limitations in the ability of ordinary mercurials in general and arsenicals in particular to penetrate into nerve tissue.

TREATMENT

I felt that further antiluetic treatment according to the classical procedure could only produce further ineffective results. I had recently been experimenting with a new form of finely divided mercury, that made a strong appeal to me because it is produced in a physical form similar to microorganisms and when intravenously injected into the body, is apparently subjected in the blood stream to the same physical forces in the body that regulate the passage of microorganisms into the invaded tissues. Considering endarteritis obliterans syphilitica to be largely a manifestation of neurosyphilis I decided that if any disinfection could possibly take place in the central nervous system, it could be accomplished in this medication, because in two previous cases of neurosyphilis I had obtained striking therapeutic results.

I started on February 20th to treat the patient with this comminuted mercury, employing the massive doses of mercury which are rendered safe by this form of the drug.

SYMPTOMS

The patient was suffering from severe pains in the left leg from foot to knee, principally in the foot; pains also in right foot. Patient was unable to sleep in a recumbent position; was obliged to sit in a chair with frequent change of position of the left foot. He was emaciated, constipated, and had no appetite. He had been treated by a number of specialists for an extended period for other conditions, such as pesplanus and suffered intolerable pains in the left leg which required the administration of opiates constantly. He was continually begging to have the leg removed.

COURSE OF TREATMENT

I began treating the patient with mercodel, giving him forty c. c. of the fifty c. c. dilution on February 20th, 24th and 28th, with the result that there was relief from all pain, and narcotics were withdrawn. It was very difficult to locate the veins in order to give intravenous injections, as they were small and hard to find, and the blood was thick and easily clogged the needle. During the month of March the treatments were continued, forty c. c. of the fifty c. c. dilution being administered on the 10th, 14th, 28th, and 29th. About March 20th two large ulcers developed, one on the scalp and one on the lip. These began as typical gumma and broke down in about eight days, discharging pus profusely. There was marked improvement of all symptoms following this reaction, and the veins became more prominent and easy to find.

On April 4th, forty c. c. of the fifty c. c. dilution were injected, and on April 8th, fifty c. c. On May 20th, the spinal fluid and blood Wassermann reactions were found negative.

By the first of June the patient was able to sleep well all night in bed, his appetite was good; and the treatment was continued with remarkable improvement in all symptoms. Forty c. c. of the fifty c. c. dilution of mercodel were injected on the following dates: June 1st, 9th, and 18th; July 2nd, 18th, and 27th; August 2nd and 8th. On August 15th a gangrenous condition of the lower part of the left foot set in suddenly, and it was considered advisable to remove the left leg below the knee, which was done on August 22nd.

At the end of three weeks the patient was considerably improved and went home. Spinal fluid and blood Wassermann reactions were returned as negative on September 18th, and on September 28th the patient went back to work.

CONCLUSIONS

All cases of endarteritis obliterans should be invariably investigated for a syphilitic background, as the blood Wassermann may be negative with a four plus spinal fluid in such cases. Hence the spinal fluid Wassermann is imperative.

Endarteritis obliterans syphilitica is probably a combination of neurosyphilis and vascular syphilis. A prolonged and heavy mercury medication is indicated, as the slowly progressive character of the disease may be completely inhibited by this treatment.

Endarteritis obliterans should be considered by practitioners in the light of these facts.

ARSENICAL TREATMENT OF GENERAL PARALYSIS

Charles Greene Cumston, M.D.
Geneva, Switzerland

Dr. Georges Richert, of the Faculty of Medicine of Nancy, has recently studied the treatment of general paralysis with the arsenical compounds in a most complete manner. Since the results of his researches have not appeared in the medical press, I give them here at first hand. In the present state of our knowledge in respect to the pathological histology of general paralysis, this process should be regarded as the most serious late accident of syphilitic infection, hence it should be treated by the most energetic means at our disposal, namely, the arsenical compounds, especially arsenobenzol and novarsenobenzol.

Although mercury is useful as a sustaining therapeutic measure, and although when properly managed it may be quite as potent as arsenobenzol in secondary or tertiary manifestations, its use for reaching and acting upon nervous lesions engendered by general paralysis would require such large doses that the entire organism would be poisoned. Therefore, some form of arsenic must be employed in sufficiently large doses to improve the general condition without causing cachexia.

Old and diffused cases of syphilis, such as tabes and general paralysis, offer great resistance to specific treatment and Richert believes that it is logical to admit that a variety of a neurotrope treponema exists which is insensible to treatment. The difficulty in the action of treatment is due to the localization of the virus in the nervous tissue in which the organism finds new means of resistance, namely, the peculiar structure of the nervous system and the numerous chemical compounds, such as the lipoids and phosphoric fats that the treponema utilizes as a means of defence.

Arsenical treatment of general paralysis should be undertaken in the very earliest phase of the disease, hence the necessity of early detection of prodromal symptoms and serological examination, especially of the cerebrospinal fluid. Not only should treatment be begun early, but should be intensive and prolonged in order to avoid the frequent neurorecidivism. Richert recommends a series of from eight to twelve injections varying between 0.30 and 0.90 centigrams each. The periods of rest should be very short, from three weeks to a month at the most, because numerous cases show not only the inefficacy but also the therapeutic danger of small doses or long interruptions of treatment when large doses have been given. Richert believes that intraspinal injections of neosalvarsan are not only useless but dangerous, while the relative meningeal impermeability does not appear to him to be a contraindication to intravenous injections. The latter permits the drug to act in association with the humoral processes that it provokes throughout the organism.

Regardless of energetic treatment, general paralysis still remains the most serious and stubborn complications of syphilis, but the more energetic the treatment, the greater are the chances that general paralysis will not develop later on. It is easier to prevent the advent of general paralysis than to cure it.

PRESENT STATUS OF BLOOD TRANSFUSION

*With Description of a New Needle Apparatus**

A. I. Rubenstone, M.D.
Philadelphia

Since the transfusion of blood from one individual to another has become popular during the past seven or eight years, through the simplification of a complicated technic, it is interesting to review briefly this procedure from a historical viewpoint. Although accounts are found in medieval writings recording the transference of blood from man to man and from animals to man, as, for example, several versions of attempts made to transfer blood to Pope Innocent VIII in 1492, yet until the discovery of the circulation by Harvey, in 1616, none of the attempts were made on a rational basis. Soon after Harvey's discovery Francesco Folli, an Italian physician, and Daniel, of Leipzig, are reported to have made transfusions. Then followed Lower, who anastomosed veins of animals in 1665 and animal blood was transmitted to man by Denys, King in England, Immerets in France, and Rive and Manfredi in Italy. The deaths were so uniform after these crude attempts that the law interdicted the practice and it practically fell into disuse for over a century. Transfusion of blood, at least experimentally, was again revived in the early part of the nineteenth century but little practical application was made of it until about the last third.

In 1855, Bischoff introduced the idea of injecting defibrinated blood and this method became popular with Prevost, Parnum, Diefenbach, Brown-Séquard, and others. The results obtained with this rather clumsy technic were either bad or indifferent, and Kocher (1877), as well as Landvis and Gesselius, preached against it. Higginson and Aveling used two cannulas attached by tubing in a bulb syringe and Landvis, in 1875, transfused directly from vein to vein, employing cannulas and tubing. Then followed attempts at inhibiting blood coagulation by phosphate of soda, practised by Baexton, Hicks, and minute quantities of ammonia (Richardson).

Then followed the era of direct anastomosis of vessels with its long and tedious technic as a result of great strides in bloodvessel surgery, notably by the work of Murphy in 1897, and Doerfler, Carrel, Guthrie, Crile and others. The first permanent suture of bloodvessels was made made by Eck, a Russian, in 1879. In 1909, Brewer and Leggett advocated transfusion by paraffin coated glass tubes interpolated between artery and vein. Modifications of the Crile cannula were devised by Berger, Soresi, Janeway, McGrath and others. Curtis and David used a paraffin coated glass bulb as a receptacle, then injected with a syringe, using a rubber tube. This method did not sacrifice any artery. It was modified by Brown and Kimpton, Percy, Satterlee and Hooker. Error in the paraffin-coating meant failure.

These direct methods were in themselves frequently unsuccessful, and the dangers to both donor and recipient, because of the inability to measure the quantity of blood which streamed from one into the other, was great. Sometimes the successes were brilliant, the recipient was benefited and the donor survived, but the risk was so great that blood transfusion in the early days of this century was regarded, not only with fear and trepidation, but the procedure was considered unsuited for emergencies. If it is recalled that until Landstiner's work, in 1901, little was known of blood incompatibility, this danger alone in transfusion should be borne in mind as a cause for many a failure.

Then since 1914 Lindemann, Hustin, Agate, Weil, Lewisohn, Rueck and others so simplified the technic of transfusion that this measure has now been added to our therapeutic armamentarium as a routine procedure, and today indirect blood transfusion is almost universally practised. It consists of two different general types of technic: a, the addition of anticoagulants, for example, sodium citrate to the donor's blood after it is withdrawn and the introduction of this blood into the recipient; b, the transference of whole unmodified blood from donor to recipient, a method not so popular as the first but far superior to it; first, because in the citrate method, exposure of the blood to the air so alters its physical make up —for example, reaction—that disturbances follow its injection into the recipient. Then the addition of the anticoagulant undoubtedly influences the structure of the blood itself, as evidenced by disturbance of blood platelets and the change in tonicity of the red blood cells and probably other unidentified mutations that are beyond our visualization through the microscope, the result being generalized reactions in a great percentage of recipients, frequently leading to fatalities, such as loss of complement.

Bertram Bernheim recently estimated that with citrate transfusion reactions of greater or less severity will occur in as high as forty per cent. His confessions, at a recent meeting of the American Medical Association, are certainly worthy of consideration. Although an enthusiastic advocate of citrate transfusion for years, he himself has almost done away with it and uses it practically only in such circumstances as war surgery and where the donor, of necessity, cannot be brought in contact with the recipient, or in rural communities, where a competent operator is lacking and the emergency is great.

Citrate transfusion requires less skill than whole blood, and is therefore more popular today. It is placed, in many instances, in the charge of a young resident physician, the procedure being too menial for the surgeon. However, whole blood can be transferred from donor to recipient with ease and rapidity if one but takes the time to practise the procedure until he becomes competent. With whole blood one encounters few reactions, and these never dangerous.

On the whole blood method, as I practise it, the technic is simple. It consists of the introduction of a needle apparatus into both donor and recipient, and the transference of the blood by means of large Luer syringes so that 1500 or more c.c. of blood can be transfused within less than ten minutes. The

*From the Departments of Pathology and Diseases of Metabolism, Mt. Sinai Hospital.

blood never comes in contact with the air. It is transferred in its natural state, the quantity carefully measured and regulated by reactions of both donor and recipient. There is little donor's blood wasted and it is rarely necessary to cut down on veins. I was always wont to place citrate transfusion as an intermediary between ordinary saline infusions and whole blood transfusion, but I honestly feel that I cannot classify it in this position as I personally prefer the saline injection to citrate transfusion.

INDICATIONS FOR TRANSFUSION

Transfusion is indicated in all pathological conditions where alteration in either quantity or quality of blood is such that it does not fulfill its physiological functions, and I have found it of great therapeutic value, and sometimes a lifesaving measure, in the following conditions:

1. The anemias: primary anemias, such as pernicious anemia, leucemia (in these types of anemia it is frequently advisable to precede it with arsphenamine); hemophilia, purpura, anemias of unknown origin probably due to endocrine or other disturbances (evidenced frequently in the anemias in children), and the anemia due to acute hemorrhage, such as that resulting from gastrointestinal lesions, ectopic gestation, postoperative hemorrhage, and in the newborn; the anemia due to infections; and the anemia due to metabolic disturbances of long standing, as, for example, diabetes, nephritis, etc.; as a measure in the anemias during convalescence after operation and diseases of long duration, for example, typhoid fever, etc. It lessens the preoperative danger.

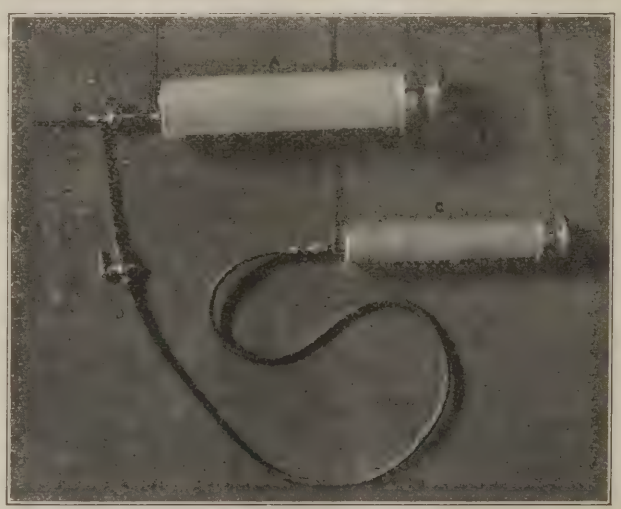

Fig. 1.—Transfusion apparatus. A, 50 c.c. Luer syringe; B, needle apparatus made in three sizes; C, small syringe made from saline; D, rubber tube for feeding saline to wash needle.

2. Transfusion as a remedy to combat infection during the course of bacteremias, as for example, typhoid fever, endocarditis, postpartum sepsis, etc., and in this class of cases frequently better results are obtained by the combination of transfusion with immune serum or the immunization of the donor with a patient's specific organism previous to transfusion.

3. Transfusion to combat toxemias, as, for example, ingested poisons, such as bichloride of mercury, poison by gases, the nausea and toxemia of pregnancy, and also in the various types of jaundice.

The amount of blood transfused will depend, of course, on the age and weight of an individual. In children less than two years of age no more than 150 c.c. of blood should be transfused; in adults anywhere from 300 to 1500 c.c. are usually given, depending upon the reaction of the recipient to the infused blood. As a general rule, patients with intravascular lesions, endocarditis, etc., should receive smaller transfusions, and patients, in whom the duration of the anemia has been of long standing with consequent degenerative changes, should receive smaller and more frequently repeated doses rather than large ones, as, in our zeal to transfer as much blood as possible, one must not disregard the danger of overloading a system that for a long while has gradually accommodated itself to a smaller quantity of fluid.

DANGERS TO BE AVOIDED IN PROSPECTIVE TRANSFUSION

1. *Compatibility of blood of donor and recipient.*—Since Landstiner in 1901 proved conclusively that agglutination of red blood cells by contact with blood serum derived from another individual of the same species occurs very frequently, his observations have been confirmed by later workers, and human blood has since been divided into four general groups; the classifications by Jansky and Moss are considered the most practical. It has been found that human blood has two different isoagglutinins. These have been designated by the capital letters A and B. The elements which are agglutinable are resident in the corpuscles and have been identified by the small letters a and b. It is self-evident that a blood cannot contain agglutinin A or B and its correspondent agglutinable substance a or b, as this would lead to agglutination of the blood corpuscles by its own plasma. However, there are four different combinations of these elements which are possible and which are shown to exist in the blood.

During embryonic development and during the first three months of life the human being does not possess specific agglutinative power in the blood. This knowledge is important, because any donor will be safe for transfusion purposes up to that period of life. After that, individuals fall into one of the four groups, which group peculiarity remains permanently throughout the life of the individual. I have found the grouping of blood according to Jansky the most practical, although the Moss classification differs from Jansky's merely in the placing of the most common group. Group 1 in Jansky's is group 4 in Moss's classification.

While it is a great convenience and also very necessary to group prospective donors so that their bloods can be matched with the recipient at any future time, it must be borne in mind that, although human bloods have been carefully classified, occasionally reactions develop due to unknown antagonisms between the matched bloods that are beyond our present recognition. These are probably minor

gglutinins that may be present in unknown quantities, even though the bloods be matched carefully. It is, therefore, very desirable that the bloods of the prospective donor and the recipient be brought into contact immediately before transfusion, so that an estimation can be made concerning the compatibility of the two bloods, and this is accomplished very simply by the test advocated by Roux and Turner.

2. *Transference of infection from donor to recipient.*—Unless the emergency is very great, the donor should always be carefully examined physically and from a laboratory viewpoint in order to determine whether he has any transmittable disease. During the course of transfusion, a sphygmomanometer should be attached to the donor so that frequent estimations of his pressure can be made. I have found that as long as the pulse pressure is maintained, the drop in systolic pressure may be very large without inducing danger to the donor. The donor is also carefully observed and watched for marked increased pulmonary rate, as indicated by yawning, sighing, etc.

The blood must be introduced into the recipient slowly and cautiously at first, as sometimes, in spite of all precautions, the patient will evidence antagonism to the donor's blood and that is usually manifest in a variety of symptoms; for example, cardiac consciousness (palpitation), precordial distress, backache, a short, sharp, repeated cough, and even pulmonary edema.

It is sometimes necessary, therefore, to stop immediately the transfusion, although less than one hundred c.c. of blood has been introduced into an adult; and although we have met such instances rarely, I would particularly emphasize the importance of regulating the dose administered to a patient according to reactions. After the first few hundred c. of blood have been transferred to the patient without any marked reaction, it is my experience that the patient will stand larger quantities well temporarily and it is very important, therefore, as mentioned previously, that the condition of the patient, previous to operation, be taken into consideration as far as total quantity of fluid transfused is concerned. As a general rule, when in doubt, it is much better to give an average transfusion, say 700 to 900 c.c. of blood, than to overload.

Following the transfusion, the donor should be kept quiet for at least six hours, given water and liquid diet, and occasionally stimulation; for example, adrenalin to overcome the acute depression. The recipient should be watched carefully and the urine examined for hemoglobinuria for at least twenty-four hours after the operation. Very frequently a secondary reaction may set in several hours following the operation, in which there occur chills and symptoms of impending collapse. It is always well, therefore, to have a syringeful of adrenalin (fifteen to twenty mm.) in readiness because we have found it almost specific in overcoming this complication.

REPETITION OF THE OPERATION.

This is usually necessary in the chronic blood dyscrasias. We have noticed, for example, that cases of profound anemia have very often by repeated transfusion been brought to a higher blood level and stay there. Sometimes in the anemias, especially in the aplastic types, it is well to repeat frequently small transfusions with the hope of stimulating the blood making organs. The intervals between transfusions must be decided according to the individual cases. Repeated transfusions are often practised as preoperative and postoperative measures, or where, on account of the patient's physical condition, smaller amounts of blood must be given, of necessity, at one time.

TECHNIC OF THE OPERATION

In the past, I have repeatedly tried the various instruments advocated for whole blood transfusion, such as the Unger, and I find that their lack of popularity is probably due to complications in their mechanisms, which account for frequent failures and also the danger of transmitting infection to donors. I, therefore, felt that the simplest possible technic evolved would produce more uniformly successful results, and have therefore devised the following simple needle apparatus. The body of the apparatus consists of a needle so modified that it fits directly the glass tip of a Luer syringe without the usual intermediate metal cap, so as to minimize the possibilities of coagulation. At the end of the shank is a simple stop cock to prevent blood loss. From the needle proper a small tube emerges which is connected with a rubber tube to a small Luer syringe filled with saline so that, during the operation, blood coagulation in the needle is absolutely prevented by the ability of the operator to flush the needle with saline at will.

The needle is inserted into the vein of the donor and the recipient. Usually arm veins are used in both adults and children, and although I have transfused ten day old infants through the arm, the easier route in the patients is through the superior longitudinal sinus. The blood is transferred through large Luer syringes. The empty syringes are carefully washed in a series of four basins of saline. I may emphasize the important fact that team work in carrying out this procedure is very essential for rapidity of action, especially when large quantities are to be transfused. I have performed over six hundred operations successfully by this method. I would therefore briefly summarize the present status of blood transfusion.

1. That the unsafe procedure of blood transfusion of a few years ago has developed, due to our increased knowledge of blood compatibility and simplification of blood technic, into the safe procedure of today.

2. That indirect whole blood transfusion is the method of choice; that the citrate method of transfusion, although simple, is indicated in such limited instances that it may be almost abandoned.

3. The apparatus used should be the simplest possible and therefore the one described is found uniformly successful.

4. As a therapeutic measure, transfusion ranks high, not only in the saving of life, but from the viewpoint of economy, in the marked reduction of the period of convalescence.

1204 Spruce Street.

Historical Medicine

The Golden Epistle

Hon. WILLIAM RENWICK RIDDELL, LL.D., F. R. Hist. Soc.
Toronto, Canada

Near the south end of the Island of Euboea was the town of Carystus of little consequence in other respects, but the birthplace of a physician of great fame—fame wholly justified by his learning and success, Diocles Carystius (the Carystian).

It is not known where and by whom Diocles was educated, but he was of the Dogmatic and not the Hippocratic School. The Dogmatics based their medicine upon *a priori* considerations, not like the Hippocratics, upon observation: they were idealistic and not materialistic; like the German philosopher who evolved the camel from his own consciousness, they evolved the causes, the nature and the proper treatment of disease by mental speculation, not by clinical experience.

Diocles was a Pythagorean, at least in the doctrine of numbers; but he had a fund of common sense which stood him in good stead in his medical practice, and gave him a high reputation for skill. A voluminous writer, he treated of fevers, materia medica, dietetics, anatomy and other medical subjects —fragments of his works are still extant. The longest of these fragments is the celebrated *Epistole Prophulaktike* or Letter on Preserving Health: this purports to be written to Antigonus, King of Asia; and, if it is genuine, was probably addressed to Antigonus Gonatas, King of Macedonia, who died 239 B. C., aged eighty, after a reign of forty-four years.

This *Golden Epistle* (as it came to be called) was frequently republished in the original Greek and in Latin translation—the celebrated Paulus Aegineta (A. D. 625-690) was especially enamored of it.

The well known French litterateur, physician and astrologer, Antonius Mizaldus (Antoine Mizauld), about the middle of the 16th Century, made a new translation into Latin which he published at Paris in 1555 in his octavo *Harmonia Coelestium et Humanorum*: this was deservedly adopted as the standard rendering, and has been frequently republished.

Amongst others, Joannes Curio made use of it, printing it in his edition of the *Flos vel Lilium Sanitatis* of the School of Salerno, a textbook of hygiene and other matters, in Latin verse which enjoyed the most unbounded popularity in the latter part of the 16th, all the 17th and nearly all of the 18th Centuries —the first edition appeared 1582, and there were many subsequent—my own copy was published by Stoer at Geneva, 1638.

From its interest historically, I give an English translation of Mizauld's Latin Version of the Golden Epistle.

> The Golden Epistle of Diocles Carystius, the Physician, second in point of time and fame to Hippocrates, to Antigonus, King of Asia, Concerning the premonitory symptoms of diseases and remedies to be applied at once—rendered from the Greek into Latin by Antonius Mizaldus.

(The Epistle begins by addressing Antigonus a the most erudite of Kings, who has no ordina knowledge of all philosophy who would not disda to receive the author's precepts with open arms ar observe them to the letter. Then it proceeds):

We have divided the human body into four part Caput, Thorax, Venter, Vesica.

CAPUT (THE HEAD)

When any disease is about to attack the head, ce tain presages and signs are for the most part accu tomed to indicate it. A heaviness of every part the head to the eyebrows, a murmuring sound in t ears, and a pulsation in the temples. In the morni the eyes water and are dim; the sense of smell deadened and the gums swell. So when you obser any of these presages and symptoms, make up yo mind that the head must be purged forthwith— mean not with the help of drugs, but taking the to of hyssop or origanum and boiling in a little pot wi raisin wine or ten ounces of soup with which y thoroughly rinse the mouth fasting; and inasmu as the phlegm is to be brought out, you will garg This is an easy remedy for diseases of the head.

It will also be very wholesome to wash the mou fasting with a decoction of mustard macerated sweetened and hot water, and at the same time draw out humor from the head by gargling; t head should, in advance, be gently rubbed, and t skin warmed, so that, the obstacle being removed, t phlegm liquefied may flow the better.

Whoever neglects the premonitory symptoms a prescribed remedies may of a certainty know th he is liable to these diseases—I mean, ophthalm glaucoma, pains of the ears, struma in the neck, di ease of the brain, sphacelismus, coryza, hoarsene nocturnal pains, lapsus vulvae, falling of the ha ulcers of the head and toothache.

THORAX (THE CHEST)

When the thorax is about to suffer from any di ease, this is presaged and preindicated by these sym toms—a certain perspiration flows from all the bod most of all at the region of the thorax; the tong swells, the saliva is salty, bitter or bilious; sponta eous pains appear in sides and shoulders beyo manifest cause; frequent yawning occurs; insomn attacks; suffocation oppresses; thirst is present; a after sleep, fatigue and anxiety; constriction of t chest, lassitude of the arms, a tremulous affecti of the hands. Such a condition it is well to assist this way—vomitus is to be produced not the crap lous kind from a banquet or that effected by a dru The best vomitus is in the morning fasting befo eating, and is that called by the Greeks, *surmaismos*

*"Surmaismos" is found in Hippocrates; the word is derived fr "surmaia" literally a radish but applied to an emetic used by Egyptians (see *Herodotus, ii,* 88) made of the juice of the radish a salt water. The word is found in Aristophanes, Pax. 1254. proverbial expression ran blepein surmaian, literally to look radi i.e., to look like vomiting.

Those, then, who wish to vomit in this manner should eat small roots or radishes, nasturtium, eruca, mustard or portulaca, then at once drink copiously of tepid water.

Those who neglect these symptoms and remedies may fear these affections: pleuritis, peripneumonia, melancholia, acute fevers, phrenitis, veternum, heat of the fauces with hiccough, and phlegmon.

VENTER (ABDOMEN)

If any disease is about to attack the venter, it may be detected by these indicia. The venter is loosened, it murmurs and is perturbed; food and drink have a bitter taste, there is heaviness of the knees, stiff rigor of spine and lumbar regions, with lassitude of the whole body beyond manifest cause.

When you observe these symptoms, the venter is to be softened and lubricated. It is better and far safer to make use of those medicines by which it will not easily be injured. In that class are beets, boiled in sweetened water, garlic thoroughly boiled; malva; sumex mercurials and every preparation of honey; for all these clear the bowels gently and satisfactorily. If any of these premonitory symptoms continue to increase, administer freely liquor of cnicus or cardamum the whole decocted, for that is gentler and safer. Smooth cabbage will also be useful thoroughly boiled in much water—this soup taken in five ounce doses with honey and salt will be very helpful. In the same way, a decoction of peas taken to the same amount as a drink has the same effect.

Those who pay little attention to these symptoms and remedies are wont to be attacked by the following diseases,—diarrhea, dysentery, lienteria, volvulus, coxalgia or ischias, tertian fever, gout, apoplexy, hemorrhoids and pain in the joints.

VESICA (BLADDER)

When any disease of the bladder is imminent it is to be recognized by these symptoms.

After a little food there is a feeling of repletion; flatus, and inflations arise, eructation and pallor of the whole body—the sleep is heavy, the urine scanty, aqueous and voided with very great difficulty; sometimes there appear buboes on the pudenda.

When such symptoms show themselves, it is high time to apply remedies. With perfect safety may be taken the roots of poppy or fennel macerated and decocted in white, thin, odorous wine—about two glasses or three ounces of this soup are to be administered per day, that is morning and evening with water of daucus, smirnium or elecampane, whichever is at hand—for they are all equally advantageous. If the patient drink water of peas macerated and boiled, along with wine, the same good result will follow.

He who unwisely neglects the above written symptoms may expect the following diseases: Hydrops, tumor of the spleen, pain in the liver, lithiasis, nephritis, strangury, colic pains, and tormina. In all the symptoms and diseases we have described, the medicines for children should be milder than for those of greater age.

Moreover inasmuch as certain diseases are more prevalent at fixed seasons of the year and certain foods are to be avoided, I add a little here beginning with the Winter Solstice.

SOLSTITVM HYEMALE (WINTER SOLSTICE)

Winter Solstice to the Vernal Equinox increases in human beings, distillations and humidities; and consequently, it is then advantageous to use the softer foods and to drink more sparingly more acid and made from origanum—and venery should be avoided—there are days, ninety in number to the Equinox.

AEQVINOCTIVM VERNVM (VERNAL EQUINOX)

This time of the year increases the black bile until the Autumnal Equinox: consequently use is to be made of cold water and everything odorous—venery is hurtful—it is safer, at least to apply what we have written about it. There are three and ninety days to the Autumnal Equinox.

AEQVINOCTVVM AVTVMNALE (AUTUMNAL EQUINOX)

This time of the year generally quantities of phlegm and thin defluxions until the setting of the Vergiliae.* It is proper, accordingly at this time to draw the humors from the head, to take the most succulent and acids foods, to produce vomitus seldom and to avoid concubitus. To the setting of the Vergiliae are numbered six and forty days.

VERGILARVM OCCASVS (SETTING OF THE VERGILIAE)

At this time the phlegm is in excess in human beings until the Winter Solstice; consequently it is proper to take what is as acid as possible and the sweetest wine, also for fat persons to use physical exercise. To the Winter Solstice there are five and forty days.

*I. e. the Pleiades.

Christian Science in the Time of Galen

JONATHAN WRIGHT, M.D.
Pleasantville, N. Y.

Recently in an attempt to get some comprehension of the ideas of the ancients as to the physiology and pathology of the kidney I found passages of other interest. In a book (1a) on the diseases of the kidney ascribed to Galen and admitted to Kühn's collection of his works these may be read. There are some reasons it seems to me why it may be ascribed to Lycus, the Macedonian, the pupil of Quintus. It is difficult, however, to believe that in the time of Marcus Aurelius and his immediate successors, that either Galen or Lycus or any one else should boldly admit, in a work on medicine, that he was a Christian. It was in the time of the early persecutions and Christians were being burned and thrown to the beasts in Asia Minor. In an article (2) two or three years ago I drew attention to those sayings of Galen

(1b) from which we infer he was not a Christian and it is not known that Lycus, the Macedonian, was one. Galen devotes a book to an acrid criticism of the works of the latter, but he does not charge him with being a Christian, which the author of this spurious but very able and attractive book in Kühn's Galen certainly was, on his own testimony.

Whoever the author may have been, after considerable discussion of the symptoms and therapy of kidney disease he goes on to say:

"When not only the causes alluded to, but also the idiosyncrasies of the temperament, contraindicate the treatment, the drugs do not harmonize with them, for they often fail. It is necessary, therefore, to keep watch and if the symptoms do not yield to the therapy, because of some peculiarity of temperament or some state of the disease, or whatever else it may be, one must change and pass over to things that are of advantage. This applies not only to drugs, but to all therapeutic measures and certain mysterious measures which do not belong to our art at all. If these are held in more regard than the others they are too near at hand and they hark back to the powers of nature. If the drugs of our art fall short because of some unknown and hidden exceptional thing, it is often necessary because of the urgency of the crisis to transfer our trust to the magic ones, the secret ways of the men of old and their whole sphere of action which has been constructed out of expert though irrational practice—like the burnt skin of a burrowing hare and goat's blood and other stupid mixtures. It is the more disgusting that the irrational experience has arisen out of nature, or from chance, or from a whim, or from mimicry, or from dreams, like a caveman, or from prophecies, or from some guess, or from something else out of which empiricism is constructed." It will be seen that this is a fairly complete analysis of the sources of primitive magic and that the caveman is a trope in its exposition, just as he is today.

"All these strange things are with us at home, but it is not necessary to put trust in them simply because we do not understand them. If from any necessity we resort to them we should not so use them lest, though they may aid us in an unknown way, they may also do injury in an unknown way." We see the worldly wisdom and professional caution of the author with a feeling of sympathy. Then he turns on us. "If the physician must practice according to rule he must make use of a bustling activity, speak confidently of functions and processes, as one acquainted through methodist doctrine with the power of the hot and cold, the dry and the moist, things sour, bitter, acrid and sweet, salty, biting and piercing, the volatile and the nonvolatile, describing the action of epispastics, the things which stop the pores and open them and all the rest of it in form." Is it possible that the family practitioner acted that way in the time of Galen? Have times changed and we with them? The toxins and the antitoxins, the vaccines and the vitamines and endocrines—but we have no time to linger over these things old and ever new. Life is short and the art long. "Why then should we Christians fail to make use of the things, which are the great mysteries for us? For I believe in these and I agree not alone bodily ills, which are matter of dispute with all physicians, are to be banished, but the diseases of the mind." If this is not an invitation to turn such cases over to the Christian Scientists and the "magical practice of the mysteries," it has no meaning.

Whether Galen ever was a Christian or not he never wrote that book. He was a bitter foe and a hard hitter, but he never turned with such biting irony, with such a sword, sharp pointed and double edged, on his own orthodox confrères.

Contributors to the Science of Medicine

ELIE METCHNIKOFF

On the sixteenth day of May, 1845, in a rambling, dilapidated old house near the village of Pannasovka in Kharkoff, a part of the wild, barren steppe country of Little Russia, an unwelcome child was brought into the world. Money was scarce and there were already four children, so the parents had decided to have no more; nevertheless, the child's mother grew to love this little son more perhaps than any of her other children. The Mecznokows named the baby Elias, or, as we know him, Elie Metchnikoff. Ilia Ivanovitch, the father, was a kindhearted spendthrift, member of a well bred but far from brilliant family, and interested chiefly in food, horses, and cards. The mother was a famous Jewish beauty, with so great a charm of manner and personality that she was nicknamed *Milotchka*, charming. Elie grew up into a frail little boy with weak eyesight, so the doctor ordered that he was not to be allowed to weep or rub his eyes. Elie soon learned to profit by this prohibition, and, at the least hint of a refusal or reprimand, would begin to whine, rub his eyes, and announce that he was going to cry. Thus he was given his own way in everything, and became for a time a very spoiled and capricious child. In reality however, he was most affectionate and loving, and very sensitive to kindness, but equally so to injustice, as was illustrated by his refusal to include in his prayers an aunt who rather foolishly made a pet of his elder brother.

When little Elie was about six, the family decided to move to Kharkoff. Here, for the first time, Elie made the discovery that he and his family were not

he centre of the universe. For instance. The Metchnikoffs occupied an apartment over that of he landlord. One day, when the children in their play were making a dreadful uproar, a servant came up from the floor below, saying that the landlady was ill and begged that the children be quiet. Little Elie, in the midst of a game, was so furious at being nterrupted, that he seized a toy whistle and blew it as hard and loud as he could through a crack in the floor, and it took the combined efforts of the rest of the family to make him stop. In after years he remembered this incident and was very remorseful, insisting that it be included in his biography, which, he considered, should contain unflattering as well as favorable comment. He hated games because his nervousness kept him from the concentration necessary to winning, and to lose he considered a bitter disgrace. His lack of robustness made him unsuccessful in the outdoor sports of his older brothers, so he refused to take part in them. Thus, by a process of elimination, he gradually isolated himself from his surroundings, and took refuge in his mother's love, his own childish games, and his work with his tutor. The latter was an intelligent youth, who not only taught the children their lessons, but endeavored to inspire in them a real love of learning. Elie's first passion was botany, which led to an intense interest in all the natural sciences. Once, at the age of eleven, he fished for hydra so eagerly in a puddle that he fell in and was rescued only with great difficulty. The children's next tutors, a Frenchman, who confined his instruction to teaching them to sing chansons, and a German, whose favorite occupation in life was drinking beer, were so indifferent to lessons that Elie found it perfectly easy to omit all study except that having to do with natural history, which he carried on chiefly by himself, on the foundation built by the first tutor.

ELIE METCHNIKOFF

The second great passion of the boy's life was music, and the love of this art remained to the end one of the dominant characteristics of his personality. Since he could learn neither to sing, nor to play on any instrument, he made himself an expert whistler.

In spite of Elie's passion and real gift for natural science, his earliest efforts along this line were attended by misfortune. His first paper, written when he was sixteen, and sent for publication to the *Bulletin of the Moscow Society of Naturalists,* had to be frantically recalled because the boy discovered, through further researches, that its conclusions were erroneous. Having decided that the Russian universities were backward, he persuaded his family to let him go to Würzburg to study under the great scientist, Kölliker. Stopping over night at Leipzig, he found a room and rushed out to buy books. When he had collected as many as he could carry, he suddenly realized that he had not the least idea where the boarding house in which he had engaged his room was located. So most of the night was spent wandering about in search of it, with his arms full of his precious books. But worse was to follow. When the ardent student reached Würzburg, he discovered that vacation time was just beginning at the university, so all the faculty and students were out of town. Nevertheless, he resolved to wait until the next term opened, pursuing his studies alone meanwhile. After a series of what must have been to his sensitive nature almost insurmountable obstacles and heartbreaking experiences, he found a little room which he could afford, unpacked his bag, and settled down to work. But such a sea of loneliness and of hatred of his squalid surroundings at once engulfed him, that he packed up again, rushed downstairs, and told the old couple in charge of the boarding house that he was unable to stay. Followed by their loud complainings and abuse, he dashed from the door and so began his journey back to Russia.

Two years later, when he was eighteen, he published his first scientific article, a memoir on the vorticella. The next year, in spite of the extreme poverty in which he had to live, he managed to spend at the famous biological centre in Heligoland, when he met many of the greatest naturalists of his time. And so began his scientific career, culminating in his work as subdirector of the Pasteur Institute in Paris. Metchnikoff's greatest contribution to the science of medicine was his theory of phagocytosis. His extension of this theory into the field of prevention of senescence, chiefly through the agency of the Bacillus bulgaricus, is still in the controversial stage. He also did notable work in immunology in general and in syphilis in particular, his experiments with Roux on anthropoid apes in connection with the latter subject having been particularly significant.

The best account of Metchnikoff's work is probably the little book entitled *Histoire d'une idée,* written by his pupil, colleague and friend, Professor Besredka, of the Pasteur Institute. His second wife, Mme. Olga Metchnikoff, has published a charming and interesting account of his life.

The development of this complex and contradictory personality is ably outlined by his wife: "The mercurial, vivacious child, goodhearted, intelligent, and precocious; the young man, ardent, impetuous, passionate, a lover of science, and of all that was exalted; the mature man, a bold thinker, an indefatigable investigator, eager, generous, tender, and devoted; the old man, in everything faithful to himself, but progressing in serenity, shining with an ever softer light, like a mountain peak in the setting sun; the martyr at last, enduring suffering with patience and resignation, seeing the approach of death without fear, observing it as he had observed life."

Editorial Articles

ARE WE APPROACHING A NEW MEDICAL ERA?

Our symposium on endocrinology includes an article by Sajous which should be read with unusual care in view of its possible influence on the future of medicine as a whole. Most of our readers will doubtless learn with some degree of surprise that so fundamental a function as that of respiration and its corollary, tissue oxidation, still await a satisfactory explanation by physiologists even though studied by them over a century. Tissue oxidation taking an active part in all functions, normal and pathological, ignorance of its rôle in the tissues cannot but retard seriously the development of our knowledge of clinical medicine in all its phases and impair our therapeutic efficiency.

This dark picture is forcefully emphasized, however, only to demonstrate the urgency of seeking light in other directions. Such light is available, according to Sajous, when the adrenals, as he has held for many years, are accepted as the essential source of the agents through which both pulmonary respiration and tissue oxidation are sustained. These organs thus become as important as the heart, acting as the purveyors of the biochemical agents which sustain thermogenesis in all tissues. The adrenal cortex, also so far an unknown quantity to physiologists, takes part according to Sajous (who ascertained this fact but recently and publishes it in this issue for the first time) in the respiratory process, the phospholipoid lecithin being the active agent, while the adrenoxidase of the medulla acts as its oxidizing agent in the tissues.

It may be well to recall in this connection that Sajous's labors in endocrinology occupy a field of their own: that of studying both the rôle they play in all functions, and the manner in which they influence disease. He is not a partisan of the random use of organic products, now being broadly criticized, and holds that what merit they possess can only be placed on a sound foundation when the functions of the endocrines are known and their therapeutic use, therefore, be poised on rational lines.

An encouraging feature of Sajous's labors brought out by the many articles he has published in our columns, is that "they destroy nothing, but add much to, and elucidate, our store of knowledge." In his opinion, a mere fraction of our actual assets in established facts in all branches of medicine, are now being used to develop medicine, a fact he ascribes to the absence of endocrine factors. These biochemical agents he assimilates to the mortar which binds together the bricks of an edifice. Construed in this light, the endocrine glands may still prove to be the foundation of a new era in medicine in which all faithful workers will receive their due.

THE PITUITARY SYNDROMES

At the International Congress of Neurology the subject of the pituitary syndromes was thoroughly discussed. In this report, based on extensive experiments, controlled anatomically, I. Camus and Roussy showed that the hypophysis is not an indispensable organ for life, that its removal is not responsible for polyuria and glycosuria, that it does not directly govern the genital functions, and does not provoke the adiposogenital syndrome. Disturbances of this nature are in reality produced by a lesion at the base of the third ventricle, involving the tuber cinereum and proximal glandular masses.

These views were confirmed by clinical data obtained by Claude and Lhermitte. Souques, Bremer and Lereboullet agree to this conclusion, with certain reserves in relation to the part played by the hypophysis in the production of the adiposogenital syndrome and especially during growth—Souques' type of pituitary infantilism. Polyuria alone persisting after antisyphilitic treatment in a case of infundibulary syndrome, reported by Foix and Dauptain, showed that the disturbance was due to a deficit of a regulating centre, probably of the tuber.

From the clinical viewpoint, Froment offered a critical study of various syndromes dependent upon a lesion or disturbance of the pituitary region, including acromegalia, gigantism, and pituitary cachexia. Great prudence is to be exercised in admitting any secretory disturbance in their development. As Bailey points out, histological examination is not sufficient to determine the histological value of a ganglion, and the same may be said of the clinical effect of opotherapy, whose interpretation is a delicate matter. Given the results obtained from the injection of an extract of the posterior lobe of the hypophysis in a case of insipid diabetes, Souques and Lermoyez suspected that there was a medicamentous and not an opotherapeutic action of the preparation. At all events, extracts of the posterior lobe seem to act on the maintenance of the vascular tonus (Beco), on the excretion of water (Gilbert, Foix, Garnier, and others), but with results that did not agree. For that matter, the disturbance

bserved, likewise their variations, were frequently elated to pluriglandular changes.

Welter analyzed the ocular phenomena, lesions f the fundus, unequal pupils, oculomotor disturbnces, and exophthalmos, while de Larpersonne welt lengthily on changes of the field of vision—emianopsia.

The treatment was envisaged in three forms.)potherapy acted regularly, but temporarily, on inpid diabetes; it gave satisfactory results in some cases f the adiposogenital syndrome, but its action varied n acromegalia. Deep radiotherapy, with a frontoemporal application, was described by Beclère, who egarded it as the least dangerous and most efficaous treatment. Many others reported excellent esults. Cushing pleaded for surgical treatment, but is radical measures should be subjected to careful nd critical examination.

HYPOTHYROIDISM WITH OR WITHOUT MYXEDEMA

Hypothyroidism is responsible for almost as many nditions of ill health and symptoms as hyperthyidism. Hypotension more frequently accompanies ypothyroidism than hypertension, so much so ined that low blood pressure may be regarded as the ost prominent diagnostic sign of hypothyroidism.

In the *Boston Medical and Surgical Journal* for ebruary 21, 1924, a number dedicated to John reston Sutherland, dean emeritus of Boston Unirsity Medical School, and the original articles of hich were prepared by associates of Sutherland as tribute of respect and affection, is an article on rtain aspects of hypothyroidism by Charles H. awrence. The article is based on the study of enty-five cases of hypothyroidism, in which clinical nd laboratory investigations were made at the vans Memorial, Boston. The summary is as folws: 1. Twenty-five cases of hypothyroidism with nical and laboratory findings are presented and scussed. 2. The most important findings in the stories, physical examinations, and easily available boratory tests are emphasized. 3. The possible lation of the abnormal nitrogen metabolism to teriosclerosis and chronic nephritis is pointed out.

The existence of a nonmyxedemic type of hypoyroidism, possibly analagous to the Levi-Lorraine pe of pituitary insufficiency is reported with tabued findings in nine such cases.

It is pointed out that it appears that the most nstant symptoms of hypothyroidism, detectable by ysical examination are, in order: subnormal temrature, bradycardia, changes in the nutrition of the in, and obesity, but that the condition may exist without demonstrable nutritional changes in the skin, or in the presence of underweight. There have been but meagre accounts in medical literature of thin hypothyroid patients. They have been overlooked, although the investigations of Lawrence and his coworkers suggest that they are by no means uncommon. The blood and urinary findings of a typical case examined by these investigators were particularly interesting, and point to damage to the kidney. Under treatment the blood chemistry returned to normal, and the urinary abnormalities also evinced a similar reparative tendency. Therefore, there could be little if any organic pathology of the kidney present, and the relation was due to depressed function only. But in untreated cases, the persistence of nitrogen retention in the blood, and of abnormal partition of the endproducts of the protein metabolism in the urine, may well explain the early arteriosclerosis which according to Falta is often found in myxedema and which as Lawrence points out, may even be casual factors in the etiology of chronic nephritis.

A considerable amount of evidence goes to show that the deranged protein metabolism of unrecognized hypothyroidism and other endocrine hypofunctions may play some part in the etiology of chronic nephritis. Morover from a diagnostic point of view, certain findings of the Evans Memorial investigators are worthy of notice because of their availability in general practice. The prominence as a diagnostic feature of low blood pressure in hypothyroidism was emphasized. In fifteen out of the twenty-five cases investigated, the kidney function as determined by the phenolsulphonephthalein test was below normal, although the urine showed no definite signs of nephritis. The examination of the blood exhibited none of the characteristics of anemia, which in patients complaining of fatigue or exhaustion was therefore suggestive of thyroid failure, and the presence of lymphocytosis was further evidence of this condition.

As Lawrence says, it would seem that without making elaborate diagnostic tests, there are in the history, physical examination, and more or less simple laboratory tests, sufficient signs suggestive of the possibility of such a condition existing. Great proneness to fatigue without definite organic disease to account for it, coupled with diminished kidney function without nephritis, no anemia but with lymphocytosis, together with a slow pulse rate and subnormal temperature—all these diagnostic symptoms should lead to the suspicion that the thyroid or other endocrine glands were not working efficiently or harmoniously, and should give rise to investigations to discover if this were so. To

neurasthenia is now attributed perhaps most of the cases with the above described symptoms, and it might be well in order to treat more effectively, to find out before labeling the affection neurasthenia, whether it is due to a deficiency of the thyroid or of other endocrine glands. The most suggestive diagnostic sign to which Lawrence draws attention is the low blood pressue, which generally distinguishes hypothyroidism. Also, that there is a thin type of hypothyroid individual, and that obesity must not be looked upon as the most outstanding sign of the hypothyroid state. It would be of the utmost value to throw more light on the cause of hypothyroidism, whether hypothyroidism is the primary cause. The key to the successful treatment most probably is to be found in a thorough knowledge of the working of the endocrine glands and in its practical application. Although the goal is yet far off, satisfactory progress is being made.

EFFECTS OF TOBACCO

A committee with a large and imposing personnel has taken up the study of the effects of tobacco, and whether our annual outlay of $1,600,000,000 for the weed is worth the price.

The first piece of research published is that conducted by O'Shea of the University of Wisconsin. It is said to be a study of *Tobacco and Mental Efficiency*. The last paragraph of the explanatory note, or introduction, gives one a peculiar impression and, we fear, some prejudice. It says, "It should be borne in mind that the present investigation is concerned solely with the effects of smoking tobacco on the intellectual processes. No effort has been made to discuss the medical, physiological, esthetic, economic, industrial, or sociological aspects of the tobacco problem." We had hoped that anyone prominent in educational work and presumably posted in psychology would be aware that any study of "intellectual processes" is a study of physiological processes. The two are one. All the records made in this study are records of the physiological effects of tobacco.

The results of this study are chiefly a reiteration of what has long been known, that tobacco is bad for some people and apparently not harmful to others. There is a wide variability in persons and a wide variability of effects from day to day in one person. "Laboratory tests yield no answer to the question, Does tobacco strengthen or does it weaken creative ability?" (Whatever creative ability is.) From the socalled scientific laboratories the researchers fall back upon the laboratory of everyday life and find contradictory answers to this question:

"The laboratory data yield no answer to the question, Does tobacco improve or does it injure judgment?" Effects upon alertness vary though they are not marked on either side. "The general conclusion to be drawn from a study of the habits of men of the past and the testimonies of men and women of the present is that tobacco is not detrimental to the mental efficiency of some individuals, though it may be a detriment to others."

In regard to the immature, the conclusions are somewhat more definite, and on the side of the deleterious effect of tobacco. "It is a significant fact that in every one of the foregoing reports from schools, smokers are shown to be inferior to non-smokers in the work of school and college. Whether this inferiority is due to the direct effect of tobacco as a drug, or to other factors, or to all factors operating together, remains to be determined; but so far as these investigations reveal the facts regarding the rôle of tobacco in school and college, it is always associated with poor scholarship." Possibly in our age of compulsory education the boy who finds himself slow of learning takes to tobacco as a solace.

The great variability of effects shown by these experiments indicates, what might be anticipated, that human tissue reacts variously to the drug. Also the tissues of most smokers probably become so habituated that the effect is chiefly due to the sucking and puffing and the benefit derived is from having something to do rather than from any specific action of tobacco.

MEETING OF THE CONFERENCE BOARD OF PHYSICIANS IN INDUSTRY

A meeting to celebrate the tenth anniversary of the organization of the Conference Board of Physicians in Industry was held in New York City, April 4th to 5th, inclusive. This conference, which was organized in 1914, stands for cooperative effort in introducing into industrial establishments the most effective measures for the treatment of injuries of employees, for promoting sanitary working conditions, and for prevention of industrial diseases. One of the features of the conference was a series of clinics arranged by the Post-Graduate Medical School and Hospital at which the physicians attending the meeting were guests.

The general sentiment of the meeting was that medical work in industry is a necessity, demanded by the existing social order; that only practitioners with high ideals of service and an adequate grasp of the problems involved can be successful in this work; that it must be conducted on a high ethical plane and with strict regard to scientific considerations; and that, when so conducted, it is a potent factor in advancing the cause of preventive medicine, both in personal and community health.

PUBLIC HEALTH SUMMER SCHOOLS

Because of an extensive demand for summer work in public health education, the United States Public Health Service has announced that arrangements have been made with Columbia University and the universities of California, Michigan, and Iowa for courses to be given in public health work during the coming summer. These will cover a period of from six to eight weeks' study, and a wide range of subjects will be included, including laboratory work, clinical demonstrations, and other methods of instruction outside the classroom. The aim of these summer schools will be: 1, to provide up to date intensive training for all persons engaged in any kind of public health work; 2, to furnish up to date instruction which will enable practising physicians to deal effectively with the more important causes of mortality and disability, especially cases referred to industrial clinics, school clinics, public health nurses, etc.; 3, to bring together practising physicians, health officers, and other sanitarians, and thus to establish a more cooperative relationship in the work of disease prevention.

Among the specialists who will comprise the faculties of the various schools are Dr. Michael M. Davis, dispensary management; Dr. Robert H. Gault, criminal psychiatry; Dr. Emery Hayhurst, industrial hygiene; Dr. William J. Mayo, noncommunicable diseases; Dr. E. V. McCollum and Dr. H. C. Sherman, nutrition; Dr. William H. Park, laboratory methods; Dr. Earl B. Phelps and Dr. George C. Whipple, public Health engineering; Dr. M. J. Rosenau and Dr. Victor C. Vaughn, epidemiology; Dr. Thomas W. Salmon, psychotherapy; Dr. John H. Stokes, syphilis; Dr. Philip Van Ingen, child hygiene; Dr. C. E. A. Winslow, public health administration; and Dr. Francis Carter Wood, cancer.

NEW INDUSTRIAL DISEASE CLINIC

The New York State Department of Labor, the College of Physicians and Surgeons of New York, and the Reconstruction Hospital in New York City, working in collaboration, have opened a clinic especially equipped and adapted for the diagnosis and treatment of industrial diseases. This clinic is situated at the Reconstruction Hospital, corner of 100th Street and Central Park West. On the staff are authorities and specialists in the fields of x ray treatment, electrotherapy, hydrotherapy, phototherapy, massage, mechanotherapy and occupation therapy.

The need for such a clinic has long been recognized by the medical profession of New York, and the step is of the greatest significance, since it concerns not only the wage earner, the employer, and the individual practitioner, but society at large, as important to the well being and efficiency of the State as a whole.

In addition to its clinical duties, the clinic will make special studies of occupational disease and will publish the results of research in new methods of treatment. Special training in industrial medicine and surgery has been planned.

Information about the clinic may be obtained from the Director, Industrial Hygiene Clinic, 100th Street and Central Park West, New York City.

Obituary.

SIR WILLIAM MACEWEN, M.B., C.M., F.R.S.,

Glasgow, Scotland

One of the greatest surgeons of modern times, Sir William Macewen, passed away at his home in Glasgow on March 22d, last, at the age of seventy-six. To Macewen belongs the title of "father of brain surgery" more rightly than to another great pioneer in the field of brain surgery, Sir Victor Horsley, to whom it is often applied. Macewen was original in everything he undertook. He was a pioneer in brain surgery; he invented an operation for the cure of knock knee which has become classical; and his researches into the acute infective inflammation of bone revolutionized modern surgical method in this direction.

He took the degrees of M.B. and C.M. at the University of Glasgow in 1869, served as house surgeon at the Royal Infirmary, and took the degree of M.D. in 1872. Five years later he was elected surgeon to the Royal Infirmary and at once adopted the antiseptic treatment of wounds, accepting the principles of Lister, but modifying the details of the technic. It may be said that Macewen was a pupil of Lister, and not only carried on the high tradition of the master, but introduced modern aseptic surgery to overcome the limitations of the Listerian methods. In 1874, when Macewen began to practice, bacteriology as a science was unknown and the brain, so far as surgery was concerned, was an almost unexplored land. Knowledge of the brain was elementary. The investigations of Broca, Hughlings Jackson, Fritsch, Hilzig, and David Ferrier, especially of the last named in 1876, throw a great deal of light on the working of the brain. Macewen was quick to appreciate the practical value of these investigations and to apply them. In 1879 he opened the skull successfully for the relief of intracranial pressure.

In 1851 Macewen drew attention to the value of Listerian methods in the operation of trephining and brought that operation into vogue. Although for long he had to combat inertia, conservatism, tradition, and prejudice, his remarkable gifts and surgical achievements were recognized in time. The University of Glasgow conferred upon him the degree of LL.D. He was elected an F.R.S. and was made a Fellow of the Royal College of Surgeons in England and Ireland, and an honorary member of the Imperial Academy of Medicine of St. Petersburg, of the French and German surgical societies, and of medical societies in Hungary, Italy, and America. In 1892 he was appointed Regius Professor of Surgery at the University of Glasgow, and Surgeon to the Western Infirmary. He was president of the British Medical Association in 1922 and in 1923 he was president of the Societé Internationale de Chirurgie when it met in London.

His address to the meeting of the British Medical Association in 1922 was notable. In it he summarized admirably the revolutionary developments which had taken place in brain surgery and in which he himself had played a leading part. In this address, too, he pointed out that pioneers were generally re-

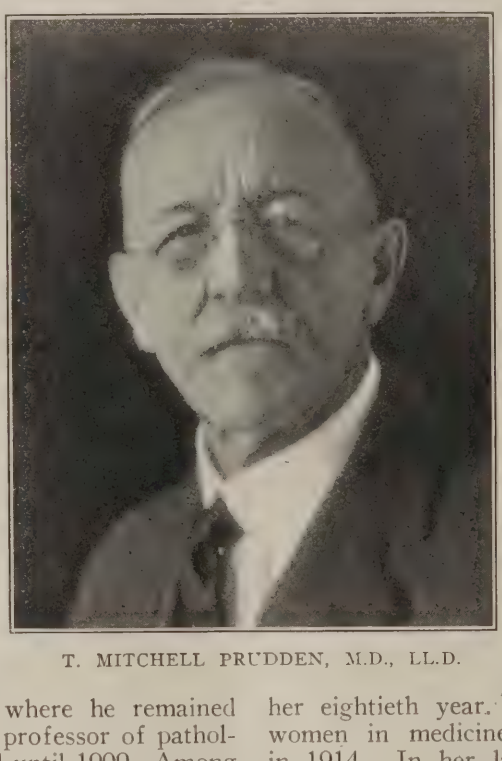
garded by their own generation somewhat lightly.

He was a keen naturalist, and his book on the antler of the deer was an important contribution to natural history and to the study of the bone growth. Macewen was a big man physically and mentally, with clear cut handsome features. He was also a man of strong opinions and had no hesitation in stating them with emphasis, and was somewhat impatient of contradiction or interference.

T. MITCHELL PRUDDEN, M.D., LL.D.

New York

Dr. T. Mitchell Prudden, one of the first members of the Board of Scientific Directors of the Rockefeller Institute for Medical Research, and member of the Council of Public Health of the New York State Health Department, died suddenly on April 10th, at his home, 160 West Fifty-ninth Street, New York. Dr. Prudden was born in 1849 in Middlebury, Conn. His parents were the Reverend George P. and Eliza A. Prudden, of that city. In 1872 he was graduated from the Sheffield Scientific School of Yale University, and two years later from the medical school of the same university. While a student in the medical school he also served as instructor in chemistry in the academic department. After receiving his medical degree, he took postgraduate courses in Berlin, Vienna, and Heidelberg, returning to this country in 1878 to become a member of the faculty of the College of Physicians and Surgeons of Columbia University. He held here the post of assistant in pathology and histology until 1882, when he was appointed director of the pathological and bacteriological laboratory, where he remained until 1892. He was then made professor of pathology, in which capacity he served until 1909. Among other teaching positions held by Dr. Prudden was that of lecturer on normal histology at Yale from 1880 until 1886. The university conferred upon him in 1896 the degree of LL.D.



T. MITCHELL PRUDDEN, M.D., LL.D.

In 1901, the date of incorporation of the Rockefeller Institute for Medical Research, Dr. Prudden was made a member of its board of scientific directors, an office which he retained until his death. In 1921, he was appointed to the International Health Board of the Rockefeller Foundation. He was a member of the New York State Public Health Board from 1914, when he was chosen for this post by Governor Glynn, until the time of his death.

Although Dr. Prudden was a specialist of the first order in his own fields of experimental pathology and bacteriology, he did not limit his interests to these subjects, as is shown by the fact that he was an active and interested member of many learned and scientific societies. Among these were the American Academy of Arts and Sciences, the National Academy of Sciences, and the American Anthropological Association. Among medical societies to which he belonged were the New York Academy of Medicine, the New York Pathological Society, the Association of American Physicians, and the Association of American Pathologists and Bacteriologists.

Dr. Prudden is best known as the man, who, with Dr. William Henry Welch, brought experimental pathology and bacteriology from the great laboratories of Germany, where the highest development of the nineteenth century in this line of research and experimental work was reached, to America. Welch established, in 1884, a laboratory at Johns Hopkins. Prudden, through his teaching at the College of Physicians and Surgeons and at Yale University and through his work with the Rockefeller Institute made a notable contribution to the development of these departments of medical science, particularly in their application to the principles of preventive medicine and hygiene. He was also the author of a number of articles on these subjects and several books, some of which are classic textbooks now used in the teaching of pathology.

As a teacher and lecturer Dr. Prudden was eminently successful, and was greatly beloved by his colleagues and students. Although *par excellence* the specialist and man of science, he was also the possessor of broad human understanding, the good comrade and warm friend.

ANN ELIZABETH CLARK, M.D. (Berne), M.R.C.P.I.

Birmingham, England

On February 25th last, Dr. Ann Elizabeth Clark died in her eightieth year. She was one of the pioneer women in medicine. She retired from practice in 1914. In her late twenties she joined Sophia Jex Blake, Agnes McClaren, and Edith Rechey at Edinburgh. She obtained a medical degree at Berne, Switzerland, in 1877, and in 1878 she obtained the licentiate of the Royal College of Physicians in Ireland. She then studied in Paris, Vienna, and Boston. Afterwards she went to Birmingham as resident medical officer to the Midland Hospital for Women, becoming the first woman on the honorary staff. Also for twenty years she was on the staff of the Birmingham's Children's Hospital.

Dr. Clark built up a large practice, chiefly among the poor. At the Women's Hospital she was associated with Dr. Lawson Tait. She refused to prescribe alcohol in any circumstances. Dr. Ann Clark and a few friends founded a home for cancer patients and when she retired from active work, some of her patients raised the sum of £750 to endow a bed at this home.

News Items

Hospital Bed Endowed.—The Progress Club, in commemoration of its sixtieth anniversary, has endowed a bed in the Hospital for Joint Diseases and one in Montefiore Hospital.

Benefit Dance.—The Eastern Medical Society of New York will give an entertainment and dance at the Waldorf on May 10th, to increase its Loan and Relief Fund, devoted to the assistance of physicians in need.

Harvard Loan Fund.—An anonymous loan fund of $2,000 to assist needy students in the school has been established at the Harvard Medical School in honor of President Emeritus Charles W. Eliot.

Endowment Fund.—A fund of $10,000 is being raised to endow a bed at the Manhattan Eye, Ear and Throat Hospital and Medical School in memory of the late Dr. T. Passmore Berens, who was professor of otology in the institution.

Course in Infant's Diseases.—A twelve day course for medical officers of welfare centres and others interested will be given by the Fellowship of Medicine and Post-Graduate Medical Association, London, at the Infant's Hospital, from May 12th to 24th.

Statue Unveiling.—Among the busts to be unveiled May 13th at the Hall of Fame of New York University, is one of Dr. W. T. G. Morton, discoverer of ether anesthesia. A tribute will be spoken by Dr. W. W. Keen, of Philadelphia.

Visit of Prominent Dutch Physician.—Dr. Alleta H. Jacobs, first woman physician of the Netherlands, who also opened the first birth control clinic in Holland, has arrived in this country as delegate to the Woman's International Congress for Peace.

Public Health Service Entrance Examinations.—Examinations will be held on July 7th in Washington, Chicago, San Francisco, and New Orleans, for appointments to the regular corps of the United States Public Health Service. Requests for information should be addressed to the Surgeon General.

Appointment to the Public Health Council.—Dr. Frederick Fuller Russell has been appointed to the Public Health Council, to take the place of the late Dr. Thomas M. Prudden. Dr. Russell was in the army medical service from 1898 to 1920, and has been identified with the study of public health problems, both in this country and abroad.

Otolaryngologists Visit Philadelphia.—The Sections of Otology and Rhinolaryngology of the New York Academy of Medicine were the guests of the Section of Otolaryngology of the College of Physicians of Philadelphia, on April 16th. After a dinner at the Union League Club, an inspection of the new building of the College of Physicians was made, and a scientific meeting held.

Philadelphia Medical Club Trip.—On May 15th the Philadelphia Medical Club will visit Washington, D. C., and the Washington Medical Society is planning a sightseeing trip for them, to include among places of more general interest, the Walter Reed Hospital, the Army Medical Museum, and the Naval Hospital. They will also be received by the President on the White House lawn.

Consultants for Veterans' Bureau.—Thirty of the leading physicians of the country have been invited to serve as consultants for the medical service of the Veterans' Bureau. The men chosen represent experts in the fields of tuberculosis, neuropsychiatry, general medicine, surgery, hospital planning and construction, and dispensaries. They include Dr. W. J. Mayo, Dr. Charles H. Mayo, Dr. George W. Crile and Dr. Livingston Farrand.

Civil Service Examinations.—Examinations will be held on May 10th by the New York State Civil Service Commission for Chief Occupational Therapist, State Hospital Commission, $1,500 to $1,800 and maintenance; Physician, Syracuse State School for Mental Defectives, $2,000 to $2,600, with maintenance for self and family; Coroner's Physician, Monroe County, part time, salary probably $780; Resident Physician, Grasslands Hospital, $2,500 and individual maintenance.

Hospital Appropriation.—Governor Smith has signed a bill appropriating one million dollars for fire prevention and safety measures in State hospitals and other institutions.

Yale Faculty Appointments.—Among the associate professors appointed are: Raymond Garrison Hussey, M.D., pathology; Grover Francis Powers, M. D., pediatrics; two teachers are raised to assistant professorships, Ethel C. Dunham, M. D., pediatrics, and Luther K. Muselman, Ph.D., M.D., obstetrics and gynecology.

Dr. Downing on Quackery.—Dr. August Downing, assistant commissioner of education, declared at the meeting of the New York State Medical Society, at Albany, that annual registration of physicians was the only way to rid the State of illegal practitioners, and stated he would resign unless the members of the society stood unitedly for a law to rid the State of quacks.

Benefit for Needy Physicians.—There will be a benefit performance of Shubert's *Vogues,* Monday, May 12th, for the benefit of the starving physicians of Germany. This benefit will be held under the auspices of the Association for the Relief of Needy Physicians of Central and Eastern Europe and of the Ladies' Aid Society of the Lenox Hill Hospital.

Henry Street Settlement Campaign.—Miss Lillian D. Wald, founder of the Henry Street Settlement, has announced the beginning of a campaign to raise one million dollars for the visiting nurse service of the Henry Street Settlement for the coming three years. Over 400,000 visits were made last year to 50,300 patients, there being 250 nurses in the service, yet all calls for assistance could not be met. The service is one third selfsupporting.

Broad Street Hospital Taken Over by Masons.—After months of negotiation the Masons of New York have assumed the maintenance and support of the Broad Street Hospital. The name will not be changed. A new superintendent will be chosen to succeed Dr. Henry C. Clark, but James Barber, founder of the hospital in 1916, continues as its president. The Board will comprise eight medical men and sixteen laymen. Dr. William H. Dieffenbach is vice-president; Troy Alexander, head of the Masonic Hospital Foundation, treasurer, and Dr. Maximilian Stern, secretary. The Medical Board will consist of Dr. William H. Dieffenbach, Dr. Maximilian Stern, Dr. Robert T. Morris, Dr. Lefferts A. McClelland, Dr. Ralph A. Stewart, Dr. Walter Gray Crump, Dr. J. Richard Kevin and Dr. John Hudson Storer.

Personals.—Dr. Owen E. Jones, of Rochester, has been elected president of the Medical Society of the State of New York.

Dr. J. Eastman Sheehan has sailed for London and Paris to lecture on plastic surgery.

Dr. Nils Heitman, chief medical officer of the Norwegian Government in the tuberculosis division has arrived in this country, and will confer with the physicians of the Rockefeller Institute on the tuberculosis problem.

Dr. Louis Friedman has been appointed visiting surgeon to Harlem Hospital.

Dr. Alexander H. Rice will repeat his trip of former years, to explore the head waters of the Orinoco River. Apparatus for a broadcasting station is included in his equipment.

Dr. Shirley Wynne has been named trustee of the New York State Hospital for the Treatment of Incipient Tuberculosis.

At a recent meeting of the medical board, St. Luke's Hospital, Dr. Henry St. Patterson was chosen president; Dr. Winfield S. Schley, secretary.

Dr. Harry Landsman has been appointed anesthetist to the Memorial Hospital.

Dr. Bernard L. Wyatt has been appointed secretary of the Technical Board of the Milbank Memorial Fund. Dr. Donald B. Armstrong, the former secretary, has become assistant to Dr. Lee K. Frankel, of the Metropolitan Life Insurance Company.

Dr. Simon Flexner, director of the Rockefeller Institute of Medical Research, has been appointed a member of the Public Health Council for another term of six years, his service on this Council having started in 1913.

Foreign Correspondence.

PARIS LETTER

(From our own correspondent)

Paris, *March 25, 1924.*

MEETING OF AMERICAN MEDICAL SOCIETY

At the last monthly meeting of the American Medical Society of Paris about fifty physicians, French, American, English and Japanese, listened with great interest to a talk given by Dr. Fuller, of the American Hospital of Paris, on the treatment of diabetes by insulin, and to Dr. Kraus's masterly presentation of the subject of late sequelæ of epidemic encephalitis, which was illustrated by moving pictures. Dr. Fuller reported results obtained at the American Hospital in certain desperate cases of diabetes where patients were saved from almost certain death by the injections of insulin. He clearly defined the indications for treatment and the methods used to determine the proper therapeutic dose.

Dr. Walter Kraus, assistant neurologist to Bellevue Hospital, New York, showed remarkable films of several patients with terrible muscular contractures following attacks of epidemic encephalitis, rendering the victims helpless and permanently crippled. Dr. Douglas McAlpine, late registrar to the Maida Vale Hospital of London, related the history of a number of cases observed in London; and Professor J. J. Lhermitte, chief of neuropathology at the Faculty of Medicine of Paris, described the pathological lesions found in numerous fatal cases examined by him. The conclusion was that many cases of socalled Parkinson's disease and chorea, particularly when occurring in the young, were due to an unrecognized encephalitis lethargica, for the early detection of which general practitioners should be constantly on the alert.

This meeting of the society was by far the most successful in bringing together physicians of various nationalities for the discussion of medical topics of mutual interest. Dr. Edmund L. Gros announced that the society proposed to present at its future meetings, in a condensed form, the teachings of various French professors who were handicapped by not being able to speak English. This should be of great interest to American students in Paris and will be a liaison between American and French physicians.

HARVARD CLUB HONORS DR. ELIOT

The Harvard Club of France gave a dinner on Thursday, March 20th, at the Marguery Restaurant, Boulevard des Italiens, in honor of the ninetieth birthday of President Emeritus Eliot. There was a full attendance.

EXAMINATIONS FOR HOSPITAL SURGEONS

The competitive examinations for hospital surgeons takes place at the Faculty of Medicine during the month of April. The examining board is composed of Professors Walther, Abrami, Baumgartner, Mouchet, Auvray, Riche and Sebileau.

SPECIAL COURSES

Special courses open to all applicants are given at the different hospitals. At the Faculty of Medicine is announced a special course in medical chemistry and applied medicine by Professor Desgrez. At the Children's Hospital, special courses under the direction of Professor Nobécourt. At the Necker Hospital a special course in urology by Professor Leguet, and at Laënnec a special course in tuberculosis.

UNIVERSITY OF NAPLES CENTENNIAL

The international celebration of the seventh century foundation of the University of Naples will occur the ninth of May and will be attended by a delegation from France.

NATIONAL CONGRESSES TO MEET IN PARIS

The National Congress of Ophthalmology will meet in Paris on May 12th; the Congress of Legal Medicine, on May 20th to 28th; the Paris Society of Biology and affiliated societies throughout France, on June 5th; the National Congress of Surgeons, October 6th, under the presidency of Professor Tuffier; National Orthopedic Congress, October 11th.

NAPOLEONIC RELICS TO BE SOLD

Some souvenirs of Napoleon's last hours are to be offered for sale at the Hôtel Drouot, the Paris auction rooms, by their owners, the heirs of Archambault, who was one of the six attendants of the Emperor at St. Helena and a witness of his last hours. The relics were brought away from the island and left by Archambault to his descendants. They include the nightshirt that Napoleon wore at his death, the bandage that was put around his head, the glass from which he drank for the last time, a piece of his coffin, a fragment of the railing around his tomb and some of the earth from it. Recently they were lent to Malmaison, and have been on view there, where, indeed, they should belong, touching relics of the tragic end of one of the greatest figures in the world's history. But unfortunately the little château Museum is not rich, and as the relics will probably fetch a high price in a salesroom it seems probable that Malmaison will lose them. The articles have been catalogued for the sale, which will be held shortly.

MEDICAL PROFESSION CRITICIZED

Exhibitions of appreciation and gratitude shown by a patient to his doctor are so infrequent that he has come to realize the consideration of his services as a simple commercial transaction and as a matter of fact. Whether it is the effect of the war or whether the public mind is becoming so thoroughly impregnated with commercialism, or just what the reason is, it would be difficult to account for the outburst of criticism and complaint directed against the medical profession, which has appeared in a certain number of responsible and reputable journals in France.

In recent publications that appeared in the *Oeuvre* doctors in general are presented as a set of pirates with no other thought than their personal interest and profit. They are represented as without the slightest interest in public hygiene and health; as the foes of prophylaxis: as the adversaries of the public movement for the control and diminution of tuberculosis, for the reason that it will diminish the number of their clients; that they do nothing to help the laboratories and are indifferent to the prescribing of antivenereal remedies because by so doing they would diminish one of the greatest sources of their enormous earnings.

Passing from the class of articles that criticize in general to those that specify individual cases, *L'Echo des Sports* treated as a mercenary robber a doctor who was capable of demanding seventy-five francs for the reduction of a dislocated shoulder and the *Cotidien* published the complaint of a patient who complained of a doctor because he charged more for a visit made on Sunday.

In taking up his pen to defend the medical profession a member of the Academy of Medicine writes as follows: "*L'Echo des Sports* demands from ten to twenty francs a line for the publication of short advertising notices. The prices of the *Cotidien* are still higher. If you were better informed of the laws of your country you would know that in a law passed by the Chamber in 1920 a tariff was established for a long and detailed list of accidents for which a doctor was permitted to charge soldiers in active service who happened to come under his care; article 19 specified seventy-five francs as a charge for a reduction of a dislocated shoulder: and you will find under article 3b that fifty per cent. is permitted to be added to the regular tariff when the service is rendered on Sunday or fête days." He characterizes as odious the attitude of certain journals, and counsels that they urn several times their pen in the ink before they ommence to write, or they may find their swords nsheathed as much to their ridicule as the attack of Don Quixote against the windmills. "You are attempting an impossible task when you try to discredit a profession whose honor is as old as civilization and who has forever exhibited a spirit of devotion and implicity of life equal to that of a priest. When you ncover some of the real abuses that exist in the ractice of our profession, none will come more uickly to your aid or be less pitiless in the prosecuion of wrong, than will the great body of the medial profession."

LONDON LETTER

(*From our own correspondent*)

London, *March 26, 1924.*

EPORT OF THE REGISTRAR GENERAL OF ENGLAND AND WALES FOR 1923

The report for 1923 of the Registrar General of ngland and Wales shows that the year was the ealthiest experienced since the report was first pubshed. Showing how the prevalence of influenza nfluences the mortality from respiratory disease, it ay be pointed out that in 1922 there were in Lonon 12,365 deaths from bronchitis, pneumonia, etc., hile in 1923 there were only 8,676. The deaths rom influenza in 1922 numbered 2,582 as against 52 in 1923. However, it is somewhat curious to ote that the number of deaths from heart disease id not differ materially in the two years. The arked effect which influenza is usually supposed exercise on persons with weak hearts is not reealed by these figures. During 1923 heart disease ecame the most frequent cause of death. It may be id that when influenza is not prevalent the killing iseases in London are, in order of precedence: eart disease, respiratory disease, cancer, consumpon, digestive diseases, and apoplexy; the causes ext in order are old age and accident. When inuenza is prevalent it becomes, because of its effect on respiratory disease, the most outstanding menace of the year. The variations in the death rate are largely a reflection of variations in the prevalence of influenza.

THE FIGHT AGAINST CANCER

Dr. W. S. Lazarus-Barlow, professor of experimental pathology at London University, addressing a meeting at Manchester recently in furtherance of the campaign against cancer, said that the fact that nearly forty-seven thousand deaths from cancer were certified in England and Wales during 1923 was sufficient evidence of the seriousness of the problem. When one came to multiply this figure by the civilized nations of the world, the total mortality reached such proportions that it was impossible to ignore it further. From an economic point of view it had to be remembered that these deaths occurred in many persons who were at the most productive period of their lives. From an intellectual point of view the annual loss to the world was incalculable. Pioneer research work had been slow and very expensive. Much ground had been cleared, so that a further extension of the work seemed opportune, but that work must be coordinated and directed into channels that seemed the most hopeful.

Dr. J. A. Murray, director of the Imperial Cancer Research Fund, delivered the first of four public lectures on cancer at St. Thomas's Hospital a few evenings ago. Dr. Murray said in part that his main conception was to regard cancer as an aberration of the process of repair. Cancerous growths were not confined to man, or to mammals, but were to be found in amphibia. A difficult feature in the study of cancer arose from its capacity to pass to different parts of the body discontinuously. Cases of spontaneous recovery from cancer were practically negligible. There was ground for comfort in that the factors which produced cancer were taking longer to produce their effect than they did in the past. If the increased mortality figures were significant at all, and not due to improved methods of diagnosis, they meant that cancer took longer to produce its effects than it did forty years ago.

AMERICAN HOSPITAL IN LONDON

An announcement was made recently that the Provisional Committee of the American Hospital in London had decided to establish their temporary quarters at the Fulcher Nursing House, 56-60 Hallam Street, Portland Street, W. The plan has fallen through. All inquiries and communications with reference to the American Hospital Association should be addressed to the Medical Director, 27 Wimpole Street, London, W. S.

HEALTH AND ALCOHOL

Professor W. E. Dixon, the renowned pharmacologist, delivered the Lady Priestly Memorial Lecture, under the auspices of the National Health Society, at the House of the Royal Society of Medicine, London, on February 16th, the subject being, Alcohol, Its Use and Abuse. The lecturer declared that all countries during the past fifty years had become and were still becoming more temperate as regards the use of alcohol. An inquiry made among a large number of publicians in London suggested that drunkenness was largely accidental and that food was the solution of the problem. It was said

that people who ate while drinking rarely got drunk. In the past we had been thinking too much of alcohol in the abstract, and too little of the alcoholic man. The high price of alcohol had already induced some alcoholics to resort to methylated spirit as a beverage. This habit existed, to a small extent, over the whole country, but was especially prevalent in Scotland. Prohibition in America had resulted in an illicit liquor traffic, which was a terrible menace to health. The solution of the alcohol problem could not be prohibition, which left all the alcoholics untreated and a menace to law, order, and the general public. Public houses should not be allowed to remain as they were mere drinking places. Surely it was desirable to substitute for them decent and reasonable places of recreation and refreshment.

A WOMAN X RAY SPECIALIST

Lady Constance Butler has been appointed director of the x ray department at St. Andrew's Hospital, and is the first of her sex to adopt this as a specialty.

ROCKEFELLER GIFT TO OXFORD UNIVERSITY

It was announced in congregation at Oxford University on February 19th that the trustees of the Rockefeller Foundation had offered to the university a gift of £75,000 for the development of the department of biochemistry.

HOUSING THE PEOPLE THE GREATEST PROBLEM

As the new Minister of Health, an avowed Socialist, is finding out, the most pressing problem of the day is to house the people properly. It has become possible to estimate with some degree of accuracy the needs of Great Britain in this direction. It is computed in the first place that about one million houses are hopelessly unfit for human habitation. These are dangerously unsanitary and overcrowded. In addition there are five hundred thousand too few houses in England and Wales, and 75,000 in Scotland. Stated in terms of the number of houses which should be built steadily year by year for twenty years, there should be 165,000 to 175,000 built annually in England and Wales. The necessity of doing comprehensive building on an immense scale is obvious. It is the greatest health question of the day in all civilized countries. The guiding motto of health enthusiasts is the destruction of slums and the erection of airy, healthy, wholesome dwellings.

SIR MALCOLM MORRIS AND SIR FREDERICK TREVES

It is curious that Sir Malcolm Morris should have survived his great friend and colleague, Sir Frederick Treves, but a few weeks. When Sir Frederick died it was Morris who succeeded him as head of the Radium Institute. They had been the best of friends for more than forty years and found fame, the one as a surgeon the other as a dermatologist. When Treves died, Morris related how he got the great surgeon to write his first book on surgery. After a brief discussion Treves said he would deliver the manuscript at ten o'clock on a day he named four months later. At ten o'clock to the minute Treves was on the doorstep at Cassell's with the manuscript and walked away with his check. It was Morris who persuaded Sir Arthur Conan Doyle to give up doctoring and take to novel writing alone. Morris had been a director of Cassell's for many years and editor of the firm's medical books.

WASHINGTON LETTER

(*From our own correspondent*)

Washington, D. C., *April 5, 1924.*

To the observant onlooker, Washington is a city of neverfailing interest, a microcosm on which the process of concentration has stamped certain characteristics which exist in all cities, but which are disproportionately stressed here. The essential phychology of the place is that of fear. Bluster though we will, almost every resident of Washington is afraid of something. That is why the atmosphere of secrecy surrounds so many conversations. The truly Washington way to begin a chat is, "Now strictly in confidence," and one hears the "shush-shush" everywhere. Yes, fear is at the base of much of the human action in the District of Columbia—fear of discharge, fear of loss of favor, fear that the people won't return one to this lovely place, and fear that your sinecure shall become that of another.

Therefore, beneath its brave surface Washington really is a sad place, a graveyard of blasted hopes and thwarted ambitions, a scrappile where old officers and discarded politicians linger in complete uselessness, waiting apprehensively for death. In the clubs the little knots of retired officers and ex-civil officials need only a few balls of yarn and some knitting needles to fulfill the requisites of the neighborhood gossip club. There they sit all day long, telling how it was, is, and ought to be done, trading their tittle-tattle in a way which is not altogether harmless. It is pitiful. These men who once did things cling to their tattered shreds of ancient glory, deluding themselves about their former actions and remarks, striving to hide their bitterness toward a world which once worshipped, but now only tolerates. One such will unblushingly relate most dazzling fictions of his own greatness, but woe be unto the youngster who tries to tell of what is being done today.

Washington is filled with men who have been washed up on the beach by a political wave which has floated them from the happy obscurity of some interior town. Even more obscure and submerged is their lot now, mouldering in the lumber room of some government department. Their state is truly forlorn, but it cannot compare with that of the officer's widow class. Here is their refuge, and many a woman once the wife of some prominent official or distinguished officer ends her days in the backwaters of some bureau, endlessly making little black marks on bits of paper. They cling tenaciously to their employment, even till they are so senile that they have to be led to and from office like little children. About ten years ago when the sanitary officers took the screens out of the public offices a terrific wail was raised, because these poor old pensioners were thus exposed to the gaze of a multitude which did not understand that these feeble old women were obliged to perform their little mechanical tasks or starve.

The sight of the retired medical officers trying to build up practices, or of the "sundowner" physician who works in some bureau by days and waits for patients at night, or of once brilliant workers pottering about on routine jobs, would be disheartening were it not relieved by the view of other groups which are successfully pushing forward in politics or science.

Small wonder is it that the true Washingtonian regards his world with a cynical eye. Continuous propinquity with the great and the near great has convinced him of the general flimsiness of the human character, and he refuses longer to be impressed.

Yes, Washington is a place of never failing interest, from the Capitol where the leather lunged spokesmen of the people vociferously orate about trivialities, to the crowds of flowerlike seminary girls on F Street, even to the Speedway where just now the first of Spring's blossoms raise their timid heads.

UNIQUE WAY TO CAPTURE RABID DOG

A reward of ten dollars is offered by Assistant Surgeon General B. J. Lloyd, of the United States Public Health Service, for the apprehension of a dog which bit his son. In his printed appeal Dr. Lloyd said, "All I desire is to find out whether or not the dog may be mad, as this is of the greatest importance. The owner will not be punished nor the dog harmed."

CHILD HEALTH DAY

President Coolidge has endorsed the Child Health Day movement, and May 4th has been dedicated to the purpose. Plans to acquaint the public with work done for the improvement of child health were decided upon at a meeting held by the American Child Hygiene Association on April 3rd. Dr. H. C. Fowler and Dr. Hugh Davis, and many other Washingtonians prominent in social and official life, are lending their assistance to the demonstration.

ANTIHEROINE LEGISLATION

Hearings on the Porter bill, which would prohibit the importation of crude opium for manufacturing heroine, were begun before the House of Representatives Ways and Means Committee on April 3rd. Dr. Charles W. Richardson, of Washington, representing the American Medical Association, advocated the wiping of heroine out of existence, declaring that not only had the Public Health Service, and the Medical Corps of the Army and Navy, discontinued its use, but the American Medical Association was endeavoring to secure its elimination from the practice of medicine. The chairman of the committee stated that opposition to the bill came chiefly from Pennsylvania, and Representative Stephen G. Porter (Republican), of Pennsylvania, author of the measure, remarked that there were a number of large drug houses around Philadelphia. The bill is exciting considerable interest, and the committee has received a number of telegrams favoring or opposing the measure.

CITATIONS FOR HEROISM

Colonel Henry C. Fisher, Medical Corps, United States Army, has been ordered to Washington where he will be in command of the Army Medical School. Colonel Fisher was recently cited for gallantry in action at Santiago, Cuba, while attending the wounded under fire. The citation carries with it the right to wear the silver star on the campaign ribbon. Colonel Thomas J. Kirkpatrick, Medical Corps, United States Army (retired), was cited in the order for attending the wounded under fire at Santiago, July 1, 1898. Colonel Joseph M. Heller, now a Washington physician, was cited for gallantry in action against insurgent forces at Nagullan, Luzon, Philippine Islands, December 7, 1899, in attending the wounded under fire. Dr. Heller was a member of Major Batchelor's "Lost Battalion" which fought its way through the hostile jungles of Luzon to the north coast and the China Sea. He is credited by War Department records as having been the first volunteer in the Spanish-American War.

MOVEMENT FOR BETTER IMMIGRANTS

The sanitary preparation of immigrants destined for the United States has been improved tremendously during the last four years, and foreign nations are now endeavoring to limit emigation to America to those nationals who will be able to pass successfully the physical and mental examinations at our immigration stations. This is largely the outgrowth of a system which was installed in Europe by Surgeon General H. S. Cumming, of the United States Public Health Service, shortly after he took office four years ago. At the present time there are well conducted emigration stations at most of the larger European ports, and announcement has just been made that Italy has established special emigrant houses in Naples, Genoa, Trieste and Bardonecchia. These are provided with hot and cold baths, elaborate systems of disinfection and cleansing; there are medical officers and attendants at these centres for the purpose of supervising the sanitary operations, culling out those prospective emigrants who have physical or mental conditions which would prevent their entry into the United States, and giving treatment for minor conditions which might prove serious or troublesome during the voyage.

Belgium has adopted the policy of allowing no emigrant to leave the country for the United States without undergoing an examination as to his physical and mental condition, and none is allowed to embark unless he is able to meet every requirement of our immigration laws.

By these wise and provident regulations which the United States Public Health Service has brought about, much hardship will be spared immigrants. It is well known that many persons sacrifice their all to come from Europe for the purpose of settling in the United States, only to be turned back at the port of entry because of some condition which might just as well have been discovered prior to embarkation. The cruel disappointments, great expense and genuine suffering thus entailed are entirely preventable, and the work which Dr. Cumming has done represents an international humanitarianism of the most practical and beneficial sort.

MALPRACTICE DEFENSE

The Medical Society of the District of Columbia has formed a legal advisory committee to assist any of its members who are made defendants in malpractice suits. A committee which had been appointed to consider the matter reported to the society that there are a great many suits for alleged malpractice brought against physicians. The legal advisory committee will investigate the merits of each case laid before it, and will act only when it is satisfied that the suit is unjust. Steps will then be taken to obtain expert testimony. The moral backing of the District Medical Society will, it is believed, do much to put a stop to promiscuous damage suits for alleged malpractice, and in the opinion of many leading physicians, this is "one of the most important steps ever taken by this organization."

Book Reviews

DIABETES

The Insulin Treatment of Diabetes Mellitus. By P. J. CAMMIDGE, M.D. (Lond.), D.P.H. (Camb.). New York: William Wood & Company; Edinburgh: E. & S. Livingstone, 1924. Pp. viii-172.

The Antidiabetic Functions of the Pancreas and the Successful Isolation of the Antidiabetic Hormone—Insulin. By J. J. R. MACLEOD, Professor of Physiology, University of Toronto, and F. G. BANTING, Research Professor, University of Toronto. The Beaumont Foundation Lectures. St. Louis: C. V. Mosby Company, 1924. Pp. 69.

Insulin in General Practice. A Concise Clinical Guide for Practitioners. By A. CLARKE BEGG, O.B.G., M.D., Ch.B. (Edin.), M.B. (Lond.), Honorary Physician Swansea Hospital. London: William Heinemann, Ltd., 1924.

As experiences with the use of insulin are increasing in number, more knowledge of its mode of action and of its sphere of usefulness becomes available. Cammidge was enabled to follow carefully some of his earlier cases treated with insulin and to compare his results with those obtained by other methods. *The Insulin Treatment of Diabetes Mellitus* is the result of his experiences, which show that insulin is by no means a panacea in diabetes mellitus. Its wonderful results when properly given and when indicated cannot be denied, but it also has its limitations, contraindications and dangers, which are reported. As time progresses, however, insulin promises to become a most valuable remedy in this metabolic defect.

After relating the history and discussing the mode of action of insulin, the author discusses the clinical results obtained with it. The insulin and fasting methods of treatment are compared. An extensive plan of studying and treating glycosurias is advocated which is quite intricate, but the author sees in it the possibility of obtaining a comprehensive picture of the metabolism in each case handled and of securing individualization in the treatment, which is very important. The types of cases requiring both fasting and insulin treatment are described. Insulin was found very useful in avoiding the dangers of anesthesia and operations. The portal effect is also discussed. Renal glycosuria and diabetes mellitus are differentiated, as are also diminished renal permeability and hypoglycemia. The best results are obtained in diabetic coma. It is asserted that the general practitioner can be safely entrusted with the use of insulin, provided he knows when and how to use it properly. The Folin and Wu method of estimating the blood sugar content is preferred by the author.

* * *

The Beaumont Foundation Lectures were the work for which the authors were awarded the Nobel prize in medicine for 1922. It is specifically directed to the basic knowledge of pancreatic physiology and the therapy of diabetes mellitus. Three lectures are reproduced. In the first lecture Macleod relates the history of insulin and discusses the pancreas in its relation to digestion and the metabolism of carbohydrates. In the second lecture, he deals with the experimental results obtained with insulin. The third lecture, written by Banting, takes up the experimental work upon insulin and its use in diabetes, including the subjects of dose, administration, overdoses and symptoms, and its use in acidosis and coma and in other diabetic complications. No one interested in the treatment of diabetes can afford to be without this epochmaking contribution to medical literature.

* * *

The author of the compact little book on *Insulin in General Practice,* recognizing that the general practitioner requires a plain and concise account of the uses and limitations of insulin and the exact method of applying it in everyday practice, aims at providing this want. For many years Dr. Begg was a general practitioner and therefore is able to appreciate his requirements and the difficulties in the way of treating patients at home. It may be said that insulin would have been more widely employed than has been the case if the general practitioner had possessed the necessary knowledge which he was unable to acquire from the highly scientific accounts written with regard to it.

Dr. Begg's book explains all that is needed respecting the use of insulin, diet and so on in clear and intelligible language. It is eminently practical and gives directions as to how patients may carry out the treatment at home systematically and with a minimum of risk. The book should be useful not only to the general practitioner but to students and nurses and to all who have diabetic patients in their charge.

ENDOCRINOLOGY

Endocrine Diseases. By WILLIAM FALTA, M.D. Translated and Edited by Milton K. Myers, M.D., with a Preface by Sir Archibald E. Garrod, K.C.M.G., M.D. (Oxon.), F.R.C.P. (London), F.R.S. Third Edition, Philadelphia: P. Blakiston's Son and Company, 1924.

Nouveau Traité de Médecine, Fascicule VIII: Pathologie des Glandes Endocrines Troubles du Developpement. By Various Authors. Paris: Masson et Cie, 1923.

Goitre. By F. DEQUERVAIN. Translated by J. Snowman. New York: William Wood and Company, 1924.

Die Krankheiten der Endokrinen Drüsen. Von DR. HERMANN ZOUDEK. Mit 173 Albildungen. Berlin: Julius Springer, 1923.

Rejuvenation. How Steinach Makes People Young. By GEORGE F. CORNERS. Introduction by Dr. A. S. Blumgarten. New York: Thomas Seltzer, 1923.

Geriatrics. By MALFORD W. THEWLIS, M.D. Second Edition. St. Louis: C. V. Mosby Company, 1924.

The Biology of the Internal Secretions. By FRANCIS X. DERCUM, M.D., Ph.D. Philadelphia: W. B. Saunders Company, 1924.

Falta's work on *Endocrine Diseases* was, in previous editions *The Ductless Glandular Diseases.* It is one of the best general textbooks on endocrinology in English. The subject is covered in a very inclusive manner, the salient points of each disorder are emphasized, and the important subjects of diagnosis and treatment receive special consideration. The clarity of presentation and the copious yet well suited addenda by the translator serve to enhance the value of the book. Another commendable feature is that too much stress is not placed on the extreme pathological types of endocrine unbalance, but the *formes*

frustes are given careful consideration. The extreme forms are always more dramatic, and they reveal many important mechanisms, yet the most fruitful field is the adjustment of those cases which show minor defects. Falta has given a comprehensive survey of the literature under the various headings. The book serves as a solid foundation for the clinical study of endocrinology.

* * *

Volume VIII of *Nouveau Traité de Médecine,* a system of medicine in French, edited by Roger Widal and Teissier and Garnier, deals with endocrinopathies in a concise form and covers most of the endocrine disturbances in a systematic fashion. There are numerous illustrations representing typical abnormalities. The apparent aim is to cover the ground without becoming too involved in theory or in delving too extensively into the voluminous literature, most of which is fairly recent. In order to conform with the rest of the series it is necessary that the subject be handled in this way. This system of medicine is excellent as a whole, and commends itself to the reader familiar with French who desires to get the point of view held in France.

* * *

De Quervain's work is a fine presentation of the subject of goitre from the viewpoint of a surgeon. The surgical and anatomical features of the various pathological conditions are admirably presented, and the medical phases of goitre are also given generous consideration. Many ingenious surgical stunts are shown which have been invented and fathered by de Quervain. Frequently the work is original and common sense methods and appeals receive preference over more brilliant if less fundamental procedures. The illustrations have been carefully selected, and are excellent in every way. The references cover a wide field. The book should serve a most useful purpose.

* * *

For the careful student of endocrinology, Zoudek presents a most useful and stimulating work. He constantly searches for underlying mechanisms and advances many alluring and apparently well rounded hypotheses. He presents a rich supply of intensely interesting clinical material, which is worked out in detail and cited in an attractive way. In many ways this is one of the most desirable books in endocrinology for those who can read German.

* * *

Corner's *Rejuvenation* is a popular treatise on the Steinach operation. An attempt has been made to dramatize endocrine achievements, which, from a scientific point of view, can serve no useful purpose.

* * *

Thewlis is a pioneer in the study of geriatrics. A second edition of his work on the treatment and care of the aged is most welcome, coming as it does when much interest has been centred about this subject, on account of the findings of Steinach, Voronoff, and other workers. Perhaps no fountain of youth awaits discovery, but we have much to learn regarding the prolongation of human life. Many things remain to be discovered regarding processes of senility, decay, and old age. This work, while incomplete in many ways, contains a great deal of material of value in everyday practice, concerning many diseases which are more common among the aged, such as cancer, diabetes, nephritis, and pruritus senilis.

* * *

Just what Dercum aims at in his *Biology of the Internal Secretions* is a trifle vague. Be that as it may, he will not find many modern workers who will agree with the major theories he has formulated in this small volume. This holds for both the endocrinological and the psychopathological material presented.

VARICOSE VEINS

Varicen. Ulcus Cruris und ihre Behandlung als Sonderfach für den praktischen Arzt. Von San.-Rat Dr. E. Clasen, Itzehoe. Zweite, vermehrte Auflage. Berlin, Wien: Verlag von Urban & Schwarzenberg, 1924. Pp. 138.

At last the much neglected subject of varicose veins and varicose ulcer has come into its own through a monograph on the subject; it has even been dignified by being hailed as a specialty. The methods with which the author has achieved some excellent results are described in most minute detail. The indifference with which this condition is generally met by both the patient and the physician has led to much suffering on the part of the patient and also considerable economic losses. Furthermore, it is a lucrative practice for quacks. The author recommends this subject as a specialty to physicians who are no longer able to follow active practice or who, for some reason or another, wish to retire to a life of greater ease.

The great value of this monograph is the painstaking detail which is followed in the treatment of varicosities and varicose ulcers, including the various kinds of bandage material, the use of the Unna zinc gelatin dressing and the Linser intravenous injection of one per cent. sublimate solution. Granulation and epithelialization of the wound is promoted by various topical applications, cauterization, curettage, etc. The aftertreatment and contraindications are also included. On the whole, a very readable and complete treatise on the subject.

HIGH BLOOD PRESSURE

High Blood Pressure, Its Variations and Control. By J. F. Halls Dally. New York: William Wood and Company, 1924.

The aim of this manual is to present to the general practitioner in condensed and applicable form the modern views regarding blood pressure. The first portion of the book, devoted to a discussion of the technic of sphygmomanometry, and a short presentation of the physiological factors that determine the level of blood pressure and its variations, is good. The author is to be particularly commended for emphasizing the importance of the diastolic pressure. One cannot quite agree with him, however, when he says on page 22 that the averages of a series of observations indicate the residual pressure. The residual pressure is the final and lowest pressure reading obtained. Dr. Dally places the level of normal diastolic pressure between 65 and 110 mm. Hg. In the experience of the reviewer a diastolic pressure persistently over 90 is to be viewed with suspicion, and one of 95 or over is certainly pathological.

The second half of the book is devoted to a presentation of the clinical aspects of hypertension and

its treatment. There are two short chapters on the arterial pressure in pulmonary tuberculosis and in relation to life assurance. The final chapter is devoted to a sketchy history of the development of the technic of blood pressure estimation. The clinical chapters are rather weak. The reader is left with no clear picture of the clinical course of the disease. Many will disagree with Dally's statement that "the majority of cases of hyperpiesia are due to toxemia arising from infective or autogenic sources." Intestinal autointoxication is considered one of the important causes.

There are a number of other statements which are open to question. It is certainly not true that "permanent hyperpiesis is the chief and most constant cause of chronic degeneration of the heart muscle." In the section on endocrine therapeutics the author accepts as fact the advertising propaganda of a firm known for the inaccuracy of its organotherapeutic claims. The author pays no attention to the important clinical and pathological studies of the German workers during the last decade.

There is a full bibliography which suffers, however, from a number of inaccuracies. Thus references 105, 106, 179 and 183 are incorrectly given. In reference 92 the German title of Romberg's book is distorted in a most curious and bizarre manner. The last paragraph on page 39 is a literal translation of a paragraph in Gallavardin's book on *La tension artérielle en clinique,* although no credit is given to the French author.

TUBERCULOSIS PROBLEMS

Problems in Tuberculosis. Administration, Diagnosis, Employment, Settlements. By Sir James Kingston Fowler, K.C.V.O., C.M.G., M.A., M.D., D.Sc. (Hon.), F.R.C.P. Oxford Medical Publications. London: Henry Frowde, and Hodder & Stoughton, 1923.

The author of this book is well known by having formerly published an interesting volume, entitled *Pulmonary Tuberculosis.* The publishers of *Problems in Tuberculosis* are the same as of the earlier work and have taken pains to devote the three last pages in the *Problems* to a review of the larger book on *Tuberculosis* which treats of the pathology and clinical manifestations, a surprising practice which our American publishers would not dare to indulge in. In this little volume of only sixty pages the talented author has given his views on many phases of the tuberculosis problem. The following are the titles of the fifteen chapters: I, Introductory; II, Landmarks and Incidents in the Struggle Against Tuberculosis; III, Prevalence of Tuberculosis—Mortality; IV, Infection; V, Diagnosis; VI, The Tuberculosis Service; VII, Notification; VIII, The Tuberculosis Dispensary; IX, The Sanatorium; X, The Settlement; XI, The Hospital; XII, Huts, Hostels, Cottages and Industries; XIII, The Settlement as a Community; XIV, Hygienic Workshops; XV, Aftercare Committees and Domiciliary Treatment.

It can not be expected that much that is not known to American medical and social tuberculosis workers can be advanced in a book of this kind, and yet there is a distinctively new feature presented in this little volume. It is the scheme for a tuberculosis settlement which, according to the author, should consist of 1, a sanatorium department—diagnosis ward, clinical ward, operating theatre (visiting surgeon), x ray installation, clinical laboratory, sanatorium block, graduated labor; 2, hospital department—hospital block; 3, industries department—huts, hostels, cottages, workshops (training, handicrafts), outdoor industries, sale of produce. The terms which may need definition for the American reader are "huts" and "hostels" as part of the industrial department. A hut would be the equivalent of our open air leanto, but only with two beds, still attached to the sanatorium but where the maintenance of the patient is less expensive than in a bed in an expensively equipped ward. Here the patients are still fed by the settlement paying so much a day. The hostel is run on the lines of an Army mess, with an inmate at the head of it who acts as caterer, such of the food as the settlement produces being purchased at the price of the day. Sir James prefers the expression settlement treatment to sanatorium treatment.

A veritable mine of maxims is contained in the concluding chapter under the title *Obiter Dicta,* from which the reviewer only desires to quote a few:

"When the struggle against tuberculosis began no one knows; when it will end, no one can tell."

"If some tuberculosis dispensaries had been more concerned with contacts and less with tuberculin, things might have been different."

"A light occupation in the open air is seldom found."

"Strange things may happen when a clinician who has 'scrapped his stethoscope' calls in a radiographer who is not a pathologist."

"A country that rejects compulsory vaccination and retains its slums must pay for smallpox hospitals and tuberculosis settlements."

PLASTIC SURGERY

Rubber and Gutta Percha Injections. Subcutaneous Injections of Rubber and Gutta Percha for Raising the Depressed Nasal Bridge and Altering External Contours. By Charles Conrad Miller, M.D. Chicago: Oak Printing & Publishing Co., 1923. Pp. 99.

This monograph deals with an entirely new subject—the therapeutic use of rubber and gutta percha for subcutaneous injections for the purposes of plastic surgery. The materials used heretofore have been found unsatisfactory for one reason or another. Several forms of rubber seem to resist the action of body fluids indefinitely and therefore these products ought to prove useful in the filling of body spaces or depressions, provided such injections are made discreetly in properly selected locations. Inasmuch as various samples of rubber have different constituents and often contain impurities incident to its manufacture, each sample of rubber used should first be tested out on animals. A special syringe and technic of injection are described. Extreme precautions must be taken to prevent infection if success is desired. The methods of preparing gutta percha for injection are described, and freely cured rubber is the best for the purposes of injection. Rubber in ether is the easiest to prepare and use, but gutta percha, softened by heat, is almost certain to be permanent, although it is rather difficult to handle. The patient must be warned that these methods are not as yet recognized as established surgical procedures.

Medicoliterary Notes.

Some interesting sidelights are thrown on the drug problem in this country by John Campbell in an article on the opium supply in the *Asiatic Review*, a British colonial quarterly, for January. His first contention is that India, the American press to the contrary, is not the source of the opium supply in the United States, but various countries not subject to international control, among them, Turkey and Persia, where the opium crop constitutes one of the chief sources of revenue.

The *American Journal of Public Health* for February contains three discussions of the relation of the public health nurse and the practising physician. The first is written by Dr. Ira S. Wile from the viewpoint of the physician; the second, from the viewpoint of the nurse, is by Alta Dines, R.N., director of nurses of the Association for Improving the Condition of the Poor, New York City; the third, from the viewpoint of the health officer, is by Henry F. Vaughan, Commissioner of Health of Detroit.

* * *

Now that secret archives in the capitals of Europe are being opened and their contents brought to light and published, documents are being found that clear up some of the longstanding historical and political mysteries of the world. The finds of the Russian Revolutionists have been given considerable press comment, but those of the German Republic are not so well known, although of equal importance. One of these is a note from the Kaiser to Lord Salisbury, written at the time of the Jameson raid in South Africa, which would undoubtedly have precipitated war at that time if Lord Salisbury had not been out of town for the week end and so did not receive the note before the Kaiser had had time to think better of his language and recall the letter unopened. Other documents show the complete innocence of Captain Dreyfus, sentenced to Devil's Island nearly thirty years ago. Still others show that Wallenstein, assassinated nearly three hundred years ago by imperial command, had been plotting to make himself King of Bohemia.—*Living Age.*

* * *

The timely and instructive paper on refuse disposal in European cities, read by George W. Fuller, consulting engineer of New York City, before the 1923 meeting of the American Public Health Association, is printed in the January number of the *American Journal of Public Health.*

* * *

Even in China, the flapper is coming into her own. Some of the papers have recently quoted a statement from the Chinese press published by a high school girl of eighteen to the fact that she declared to be null and void a betrothal agreement made during her infancy, according to the age old Chinese custom, by her parents and those of a young man whom she did not wish to marry.

* * *

In a study recently published by Prof. Murchison of Johns Hopkins University, it was found that about seven thousand prisoners in America today are college graduates. The list includes lawyers, ministers and doctors.

* * *

America, it seems, is not the only country to be accused of suffering from the "pretty girl craze," as evidenced by its posters, advertisements, magazine covers, etc. Paul Westheim writes in an article on the psychology of bad taste, quoted from *Die Glocke* in a recent issue of the *Living Age,* as follows: "The public does not want the depiction of human character. It wants a series of romantic variations, with a pretty woman, well dressed, for the theme. Then it can enjoy the fashionable world and fashionable women as it sees them in its nightly dreams. The fact that they are so overprettified that all traces of earth's toil and all human reality are falsified out of them makes them popular."

* * *

The Imperial Cancer Research Fund, under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England, has issued its eighth scientific report. The volume is divided into two sections: first, papers dealing with the behavior and character of cells already cancerous; second, papers dealing with the induction of cancer—the changes which cells undergo in becoming cancerous. The cuts and plates, which are numerous, show the clarity and excellence characteristic of British medical reproductions.

* * *

The Street of the Eye, by Gerald Bullett, is a collection of short stories about psychologically abnormal types. Most of them are excellently written and real thrillers in arousing and holding the reader's interest.

* * *

The American *Review of Reviews* for April translates excerpts from the abstract of an interesting address on race psychology delivered recently by E. Oberhummer before the Austrian Academy of Sciences in Vienna.

* * *

Prof. Raphael Dubois, of the physiological laboratory at Tamaris-sur-Mer, France, is reported to have announced that he has discovered that the administration of oxygen will cure both seasickness and mountain sickness.

* * *

In view of the interest in James K. Hackett's revival of *Macbeth,* it is worthy of note that the first extant review of that play of Shakespeare was from the pen of one Simon Forman, M.D., of London, known as an astrologer, quack, and dealer in arts of magic. He kept a kind of diary, which he called *The Book of Plays and Notes Thereof,* and in which he tells of seeing *Macbeth* at the old Globe Theater on April 20, 1610.

* * *

The Training of Midwives is the subject of a full report by Janet M. Campbell, senior medical officer for maternal and child welfare of the British Ministry of Health, published as *Report No. 21 on Public Health and Medical Subjects.* The report deals with conditions in all of the countries of Central and Northern Europe except Russia. A full abstract by Taliaferro Clark of the U. S. Public Health Service may be found in *Public Health Reports* for February 22.

* * *

A series of lectures delivered at the Lowell Institute, Boston, in 1922 by Prof. William M. Wheeler, on *Social Life Among Insects,* is now available in book form. The publishers are Harcourt, Brace & Co., New York. One of the observations emphasized by Prof. Wheeler is that a species developing parasitism is doomed to ultimate extinction, and that change from an independent, individual form of existence to a social state is the straightest road to acquiring countless inescapable parasites. Is there any significance in this for man?

* * *

Standards of Care for Convalescent Children, is the title of a small pamphlet recently issued by the Sturgis Research Fund of the Burke Foundation. The writer is Hortense Kahn, who presented the subject as an essay for a Master's Degree at Johns Hopkins University.

* * *

A play that aroused, when presented recently at the Comédie Francaise in Paris, as great a commotion as did *Hinkermann* in Dresden, is Paul Raynal's tragedy, *Le Tombeau sous l'Arc de Triomphe.* The play deals with an imaginary career fashioned by the playwright of the Unknown Soldier and his love. The play has been represented in this country by the press as mere Parisian pornography, but those who have seen it find nothing shocking or really immoral in it.

* * *

A very useful section of the new *Book Review Supplement of Mental Hygiene* is a full but selected list of books on mental hygiene and allied subjects, by Dr. Frankwood E. Williams. The titles are classified as General, including anthropology, biology, psychology, and miscellaneous; Childhood; Psychoanalysis; Mental Disease; Mental Defect; Delinquency; War Neurosis; Nursing; and Journals.

* * *

In the article by Dr. Frederick Willius on "Changes in the Mechanism of the Human Heart Preceding and During Death," published in our issue for March 19, 1924, a regrettable error occurred. In Fig. 1, the letters on Parts I and II were transposed, thus making the explanatory legend wholly unintelligible. Corrected cardiograms will appear in the author's reprints.

Abstracts from Current Literature

ENDOCRINOLOGY

The Gas Exchange in Diseases of the Thyroid Gland.—John T. King, Jr., (*Bulletin of the Johns Hopkins Hospital,* September, 1923), analyzed a series of forty-eight one hour periods, the observations being made on patients with thyroid disease in the basal condition, with the following results: The average CO_2 elevation is 0.8 per cent. less than the elevation of direct calories, and there is an average error in correlation with direct calories from hour to hour of ± 5.2 per cent. The average elevation of indirect calories is 2.1 per cent. above direct calories for those experiments. The error in the correlation of direct and indirect calorimetry from hour to hour is ± 5.8 per cent. The average elevation of O_2 is 6.5 per cent. above the direct calories, and the average error in correlation from hour to hour is ± 5.8 per cent. The average gaseous ratio is 0.791 in the first hour and 0.796 in the second. In the third hour it is 0.767. In observations on quiet patients the gaseous ratio falls in the second hour in eleven cases and rises in sixteen. In restless patients it falls in five cases and rises in six. The conclusion is reached that CO_2 elimination affords the best index to the heat production in thyroid disease, as judged by direct calorimeter experiments.

Treatment of Hypothyroidism by Thyroid Transplantation.—Albert Kocher (*British Medical Journal,* September 29, 1923), believes that homotransplants from the hypertrophic thyroid gland in a severe but recent case of exophthalmic goitre, which shows cellular hypertrophy and active new formation of vesicles, are preferable. The upper pole or posterior part of the gland near the superior thyroid artery should be selected. It is most important that the transplant be implanted immediately after its removal from the donor. The author prefers the upper end of the tibia for the site of implantation because it is very vascular and also because it has a special affinity for thyroid tissue. The transplant may also be implanted into the sheath between the fascia transversalis and the peritoneum, or into the peritoneal cavity. In the latter case the parietal peritoneum should be sutured over the transplant and not left free in the peritoneal cavity. Success is achieved only if the wound heals without a rise of temperature or any other postoperative reactions. The preoperative and postoperative treatment are most important. Thyroid should be administered for some time before and several weeks after the transplantation, especially in total congenital absence of the gland.

Functional Liver Tests in Thyroid Diseases.—Otto Pollak (*Monatsschrift für Kinderheilkunde,* October, 1923), observed an abnormally increased excretion of amino acids in goitre in children after the oral administration of fifty gm. of gelatin, but no such functional liver disturbance was demonstrable in cases of myxedema. The galactose test also showed a greater excretion of galactose in the urine than is normal. The Vidal hemoclastic crisis was positive in both the goitre cases in children and in myxedema. Even though the tests were few in number, the author, nevertheless, feels justified in calling attention to the fact that thyroid gland disturbances in children are associated with and followed by functional disturbances in the liver.

Treatment and Prophylaxis of Thyroid Insufficiency.—Arnold Josefson (*Hygiea,* November 15, 1923), who in 1915, in his paper on endocrine disturbances, stated as his opinion that large doses of thyroid extract were preferable to small doses in cases of thyroid insufficiency, now adduces fresh proofs to substantiate his assertion. He describes some cases in which there were none or only insignificant results from small doses but in which large doses, 0.30 x (1—6), had a notable and lasting effect. By means of photos and röntgenograms—many illustrations of which appear in his article—he shows how quickly feeding with large doses of thyroid extract produces effect. Also he adds new observations on the interdependence between the organs of internal secretion and capillary tonus. Thus in a case of acrocyanosis he observed with the aid of capillaroscopy on the fingers how quickly the capillaries became normal again under treatment with thyroid extract. The author considers that enlargement of the thyroid gland is often a sign of hypothyroidism, and not as might be expected of hyperthyroidism, the gland becoming enlarged in its increased effort to fulfill its functions, an attempt of nature to compensate for the deficiency of thyroid gland, and exemplifies this with cases of large goitre that have become quickly reduced by treatment with thyroid extract. The importance of prophylaxis is pointed out; thus to mothers who show signs of hypothyroidism or belong to families affected with endocrine disturbances should be administered thyroid extract during pregnancy and lactation. Also in some strumous districts of Sweden he advises iodine treatment as a preventive measure, this latter, however, with extreme care and watchfulness, as harm may be done thereby.

Effect of Iodine upon the Thyroid Gland.—B. Breitner (*Wiener klinische Wochenschrift,* August 23, 1923) maintains that the colloid should be considered as a stored secretion of the thyroid gland, that it is activated by iodine according to the needs and given up to the general circulation. In hyperemic goitres the delivery of the stored secretion is accelerated by medication with iodine, but in parenchymatous goitres, on the other hand, it is inhibited. The differences observed in the effect of the iodine in exophthalmic goitre may be ascribed to a different etiological factor of the goitre. The inhibition of the secretion is responsible for the favorable action in certain forms of exophthalmic goitre, which are due to hyperthyroidism.

Thymus Gland Enlargement in Infants.—E. J. Barnett (*Northwest Medicine,* November, 1923) says that an enlarged thymus occurs frequently in infants and causes symptoms noted by the mother, usually mild, but persistent or recurring with exacerbations. The predominating symptoms are choking spells, especially after nursing and during the night. Severe attacks of cyanosis may be the only complaint. A persistent cold in an infant from shortly after birth is indicative of this condition. Percussion of the chest often gives surprisingly accurate information as to the presence and lateral extent of the gland. The direct diagnosis depends on fluoroscopy and the radiogram. One x ray treatment is usually sufficient to relieve the symptoms and cause atrophy of the thymus.

Importance of the Adrenal Glands in the Action of Certain Alkaloids.—Charles W. Edmunds and Putnam C. Lloyd (*Journal of Laboratory and Clinical Medicine,* October, 1923) observed a leucocytosis following the administration of physostigmine to normal dogs, which, however, is considered an epinephrine effect, due to the epinephrine present in increased amounts in the blood due to the stimulation of the adrenal glands by the physostigmine. Surgical removal of the adrenals, or other influences, such as ergotoxin, atropine, and curare, which will remove these glands functionally, prevents the leucocytosis following physostigmine. The red blood cells are not affected by small doses (0.5 mg. per kilo of physostigmine), but 0.7 mg. per kilo causes a marked increase in their number in the circulating blood. This does not seem to be a phenomenon of altered distribution, but due to an action on the bone marrow.

Influence of Intestinal Bacteria upon the Thyroid Gland.—D. J. Harries (*British Medical Journal,* March 31, 1923) concludes as follows: 1. Exophthalmic goitre is due to the excessive absorption of tryptophan from the intestine; this in turn is traceable to the absence of the indole producers from the intestine. 2. The absence of the indican from the urine indicates the absence of indole producers from the intestine. 3. In exophthalmic goitre the early disappearance of indican from the urine is of serious prognostic importance. 4. Operative surgery has a definite place in the treatment of exophthalmic goitre. Medically, much can be done by suitable dietetic measures. 5. Diffuse parenchymatous goitre is characterized by an excess of indican in the urine, suggesting an excessive destruction of tryptophan. If this excess gives place to a diminution or complete disappearance of indican, that suggests that the case is assuming the exophthalmic form. 6. Myxedema is due to atrophic changes in the thyroid gland, which loses its capacity for dealing with the circulating, tryntophan, whether that substance be excessive, deficient, or normal in amount. The disease is thus compatible with the presence or absence of urinary indican.

Dangers of Iodine Therapy with Special Consideration of the Modern Efforts in the Prophylaxis of Goitre.—O. Roth (*Schweizerische medizinische Wochenschrift,* September 13, 1923) endeavors to show that severe symptoms of hyperthyroidism may be produced, especially in adults, following the use of small doses of iodine in proprietary preparations, such as are recommended in the schools of Switzerland and purchasable in the drug stores. The symptoms receded under suitable treatment only in some of the cases. In one case dilatation of the heart resulted, with perpetual arrhythmia, which could not be relieved by treatment. Another patient, who previously was able to take iodine without injury, suffered from severe symptoms even with the same dose. The tolerance for iodine varies in the same individual at different times. The use of iodized table salt, as has been practised in some of the cantons of Switzerland, may lead to hyperthyroidism. Unless greater care is taken in iodotherapy, the whole subject of the prophylaxis of goitre may become discredited.

DIABETES

Insulin Therapy of Diabetes Mellitus. — H. Sahli (*Schweizerische medizinische Wochenschrift,* August 30, 1923) states that the diabetic disturbances consist in an excessive mobilization of the sugar in the liver and in an excessive formation of ketone bodies in the liver as a result of the diminished formation of lactic acid from glycogen and sugar. As a result of its hormone effect, insulin strikes at the root of the disturbances and consequently affects the hyperglycosuria or glycosuria and acidosis to approximately the same extent. This is the crux of the great advance of insulin therapy, inasmuch as the purely dietetic treatment frequently increases the acidosis in severe cases, as long as it is not improved by an improvement indirectly and secondarily of the carbohydrate tolerance. Only moderately severe and severe cases of diabetes which are not affected by dietary measures alone, should be treated with insulin, and this insulin therapy should be carried out with strict individual regard to the dose, with a careful observation of the diastatic rules according to the most recent points of view. The future will show to what extent insulin is indicated in other diseases, as for example in obesity, diseases of the liver, and in endocrine disturbances (exophthalmic goitre), and to what extent it may do harm or lose its efficiency in diabetes as a result of the system becoming accustomed to it (diminution of the activity of the pancreas?).

Diabetes and Insulin Therapy. — Alfred Gigon (*Schweizerische medizinische Wochenschrift,* September 20, 1923) explains his experimental findings in animals according to the theory of a diminished consumption of sugar. The sugar, as a result of the action of insulin, reaches the proper spot in adequate form, the hunger for sugar is appeased, the hyperglycemia is reduced and the formation of glycogen can proceed. The following plausible hypothesis may be advanced: As a result of the insulin, the sugar is decomposed into physiological intermediate products, which are utilized by the normal and diabetic organism. In diabetes, there is a deficit of such products as a result of the improper decomposition of sugar. If the deficit is covered, a well being immediately sets in. An overproduction of these decomposition products leads to severe disturbances. The injection of glucose provides conditions, which render the overproduction of such products partly harmless. The ion concentration should be thought of in this connection. The insulin displaces the ion concentration toward the alkaline point and the glucose displaces it toward the acid side. Still another factor to be considered is the effect upon the albuminous metabolism. Under the action of insulin the albumin sugar seems to be utilized more advantageously. It is not absolutely certain that the carbohydrate disturbance is the primary factor in human diabetes, as it is a well known fact that in diabetics results are achieved with the reduction of the ingestion of albumin, which are impossible with a onesided limitation of carbohydrates. It is also an interesting fact that the internal secretion of the pancreas may be rapidly destroyed by trypsin, whereas it is not affected by the lipase of the pancreatic juice. An abnormally abundant albuminous diet produces an increased production of trypsin. Is it not possible to imagine, that as a result of this increased labor of the pancreas in the formation of trypsin, the activity of the islands of Langerhans suffer and become insufficient after months and years?

Insulin Treatment of Diabetes.—W. Löffler (*Schweizerische medizinische Wochenschrift,* September 27, 1923) calls attention to the fact that the aim of insulin therapy is not the cure of coma but its avoidance. This is possible in a great number of cases, which would end fatally from coma without the use of this effective remedy even with the aid of a most suitable diet. Attention is also called to the possibility of overdosing and its unpleasant sequelæ. When injecting insulin we must always be absolutely sure that the organism still has a sufficient amount of carbohydrates at its disposal so that an excessive fall of the blood sugar can be eliminated. Insulin is, therefore, contraindicated in renal glycosuria—the socalled renal diabetes, which is not so rare as is generally believed. Renal glycosuria is characterized by the fact that the blood sugar content in the fasting state is normal, that an alimentary increase in the blood sugar does not occur or is less extensive than normally, and that, nevertheless, a more or less pronounced glycosuria exists, which, however, is independent of the carbohydrate content of the food. As the renal glycosuria is not due to a raised blood sugar level but to an abnormal permeability of the kidney for glucose, a marked reduction of the blood sugar level by insulin might lead to serious disturbances. The postulate should be established, that in every case in which insulin is used a careful control of the ingestion of carbohydrate and of the excretion of sugar in the urine must be carried out. Blood sugar estimations are also very valuable. If these precautions are not carried out, the patient is subjected to injury and this effective remedy will become discredited. The sterilization of the syringe and needle is absolutely necessary owing to the marked predisposition of diabetics to infection. The inunction of insulin has the disadvantages of great wasting in the material and the possibility of infection of the skin. In addition to its enriching the therapy of diabetes insulin also has the property of advancing our knowledge of carbohydrate metabolism and the pathogenesis of diabetes. The manner of its action is not as yet entirely clear. It may be possible to differentiate various forms of diabetes with the aid of insulin. The treatment with insulin requires the greatest amount of individualization.

Diet Lists for Diabetes in Conjunction with Treatment with Insulin.—All medical journals are overflowing with papers on the treatment of diabetes with insulin. The prevailing opinion is perhaps expressed by A. Muir Crawford (*Glasgow Medical Journal,* December, 1923) "Insulin does not cure diabetes. No doubt, when it is administered the symptoms disappear, the patient regains health and strength and puts on weight, and after years of misery he may be made fit to return to a useful occupation and to a happier life, but on stopping the insulin the symptoms return. Yet we must remember that diabetes, if untreated, is a progressive disease, and that if treated without the aid of insulin benefit can only be obtained in many cases by a cruel and almost unbearable restriction of diet; whereas, with its aid, not only is the patient enabled to enjoy a more liberal and more pleasant dietary resulting in a general all-round improvement in physical fitness, but there is the hope that the strain on the islets may be so far relieved that they can develop their natural powers of regeneration with ultimate advantage to the patient.

But it seems evident that the diet still needs to be restricted, and diet lists have already appeared in a number of journals. Seale Harris (*Southern Medical Journal,* March, 1924) gives an excellent discussion on the use of insulin by the general practitioner and presents six well worked out diet lists for diabetics of various ages and weights, It is well to bear in mind the warning with which he starts, that it is not possible to prepare a diet list that will suit all cases of diabetes; that each patient has to be dieted and treated with insulin according to his individual requirements, depending upon his age, height, weight, and upon the kind and amount of work he is doing. It is also important to consider the patient's general condition as well as to know whether or not he has acetone and diacetic acid in his urine. "What is one man's meat is another man's poison" is surely true in diabetes. For instance, if a patient has a large amount of fatty acids in his blood and tissues, the diet that the average diabetic needs would increase the acidosis and perhaps bring on coma.

The diet lists sent out by well meaning manufacturers and those given in certain text books enumerating the foods the diabetic may take and those in the "must not take" or

"to be avoided" lists are almost as bad as letting the patient eat what he wants. No diet list is of value in diabetes unless it gives the quantities of food to be taken; and it is not possible to outline in any one diet sheet anything like the quantities of the various foods needed by diabetics of all ages, weights and conditions.

Frederick Hipwell presents two diet lists in an article entitled the Practical Application of Insulin in Diabetes (*Canadian Medical Association Journal,* Feb., 1924).

The Use of Insulin in Combined Diabetes Mellitus and Tuberculosis.—Labbé, Bith and Boulin (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris,* January 3, 1924), report four cases of diabetes with poor nutrition and acidosis, complicated by pulmonary tuberculosis, in which insulin was used. In none of these cases did the insulin appear to exert any aggravating action on the tuberculous condition. In one instance the temperature, slightly febrile on admission, descended to normal when the insulin treatment was given. In one case, a tuberculous anal abscess was incised and healed rapidly, without sinus formation. While the insulin treatment neither improved nor aggravated the lung condition, it enabled the patients to deal with the tuberculosis as if they were not diabetics. Their general condition was greatly improved, sensations of malaise, weakness, lassitude and mental depression disappearing and the weight increasing. Their carbohydrate tolerance being increased, they were enabled to take more food. The acid intoxication, threatening at first in some of the cases, always quickly disappeared. The insulin seemed to act as favorably on the diabetes as if the patients had not been tuberculous. Apparently, pulmonary tuberculosis is not a contraindication to the use of insulin, as some have asserted, though it is doubtless advisable to keep a careful watch on the pulmonary lesions in such cases.

Studies of Diabetes Mellitus.—William S. McCann and R. Roger Hannon (*Bulletin of the Johns Hopkins Hospital,* March, 1923), in a study of the respiratory exchange following the ingestion of glucose, glycerol, calcium hexose phosphate, and calcium glycerophosphate, state that there are apparently two types of change produced in the respiratory exchange after the ingestion of glucose by individuals who are in the stage of severe diabetes with glycosuria and hyperglycemia. In one type the respiratory quotients are depressed for an abnormal length of time; in the other, the quotients rise at a rate approximately normal. All the individuals of the former type were responsive to treatment and subsequently a good carbohydrate utilization. The two subjects of the latter type failed to respond to treatment of any kind. The clinical improvement of the patients of the first type is accompanied by an increased ability to oxidize glucose. These two different types of response to the ingestion of glucose raise the question of whether there may not be two or more types of diabetes mellitus at present clinically indistinguishable, but in which the disorder involves different mechanisms. Hexose phosphate taken in the form of an ester of phosphoric acid was more readily oxidized in certain diabetics than was glucose. The effect of the ingestion of calcium glycerophosphate upon the respiratory change was variable.

Duration and Magnitude of the Hypoglycemia After Insulin.—Elmer L. Sevringhaus, Elizabeth Kirk, and Harold J. Heath (*American Journal of the Medical Sciences,* November, 1923) present the following conclusions. 1. In normal human subjects the extent and the duration of the hypoglycemia after the injection of insulin are so variable that the result cannot be predicted from the dose per kilo of body weight. 2. The extent of the hypoglycemia and the duration of the low level are roughly parallel to the dose of insulin. 3. The depression of the sugar tolerance curves by insulin is not uniform in type or extent. 4. With increasing doses of insulin both the extent and the duration of hypoglycemia are increased. 5. The blood sugar concentration at which symptoms of overdoses of insulin appear vary in different individuals in the region from 40 mg. to 65 mg. per 100 c.c. of blood. 6. The concentration of sugar in the urines of normal subjects does not follow the blood sugar level with or without insulin. It is related more closely to the urine volume. 7. The treatment of diabetics with small doses of insulin at intervals of not less than six hours is preferred to the use of larger doses at very long intervals, or of smaller doses at too short intervals. 8. Intranasal application of insulin is without effect.

GENITOURINARY DISORDERS

Treatment of Syphilis.—Dind (*Schweizerische medizinische Wochenschrift,* October 18, 1923) calls attention to the fact that the lesions on the mucous membranes and around the anus and vulva in syphilis show a marked tendency to persist and the cutaneous eruptions show a marked tendency toward spontaneous disappearance. Therefore it is impossible to draw any conclusions regarding the efficacy of treatment from the disappearance of lesions on the skin. He is in favor of using the arsphenamine preparations as a routine and mercurial preparations only during the intervals of treatment.

Intraspinous Salvarsan Therapy in Parasyphilitic Diseases.—Eugen v. Thurzó (*Wiener klinische Wochenschrift,* September 20, 1923) states that, with a suitable method and dose, the intraspinous treatment with neosalvarsan, in itself, is absolutely harmless for the patient. In many cases of late syphilitic nervous lesions, which are refractory to other therapeutic measures, the spinal fluid findings and the clinical picture show more or less improvement after intraspinous treatment. This therapy may therefore be used not only in parasyphilitic diseases, but also in early syphilitic conditions of the nervous system and in cases of latent, secondary, and recurrent syphilis, in which the spinal fluid is pathological and in which only a slight improvement is obtained after other methods of treatment.

Pathological Changes in the Kidney in Congenital Syphilis.—Ernesto de Souza Campos (*Bulletin of the Johns Hopkins Hospital,* August, 1923) found histological changes in the kidney in sixty-nine cases of congenital syphilis, in the interstitial tissue and the parenchymatous apparatus. The interstitial changes consisted mainly of a cellular infiltration around the bloodvessels of the cortex. The medullary zone was rarely affected. The kidney pelvis was frequently infiltrated with cells which have the same structure as those around the bloodvessels. The capsule showed only a slight infiltration in a few cases. The infiltrating cells of the kidney in congenital syphilis were similar in structure to the bone marrow cells, being nongranulated myeloid cells, neutrophilic and eosinophilic myelocytes, normoblasts, and megalocaryocytes. The kidney in congenital syphilis is retarded in its development, as is shown by the presence of the "neogenic zone" in kidneys of full term stillborn syphilitic babies, while this is not observed in normal full term babies.

Bacilluria.—Julius Burnford (*West London Medical Journal,* October, 1923) states that when this condition is suspected the urine should be obtained with a catheter from the female, but in the male it is sufficient to collect the urine after allowing the first part to escape and wash out the urethra. Bacilluria is now looked upon as an entity which manifests itself in an acute or chronic form with periods of quietness alternating with exacerbations, or in a latent form of indefinite duration, causing no symptoms but undoubtedly potent for harm. More frequent in the female, it occurs at all ages but especially in pregnancy and during the puerperium. The condition is usually due to the Bacillus coli, though the Bacillus proteus, Bacillus paratyphosus, Bacillus typhosus, Bacillus pyocyaneus, streptococci, Micrococcus melitensis, and Bacillus tuberculosis are occasionally also found. When a bacilluria resists the ordinary methods of treatment, some such condition as calculus or chronic cystitis should be suspected. The primary types show clinically an acute form with active symptoms, rarely fulminating, with intermittent pyrexia, vomiting, rigor, and sometimes diarrhea. Characteristically there is frequent micturition of highly acid urine, the passing of which produces a scalding sensation. The urine contains pus and Bacillus coli. The symptoms usually subside with treatment, especially in very young children. The various types include that of pregnancy and the puerperium, that occurring after appendectomy and the latent type. This condition must be differentiated from typhoid fever, influenza, malaria, tropical fevers, acute abdominal conditions, and septicemia. The treatment includes the reduction of the acidity of the urine by potassium citrate, urotropin, autogenous vaccines, and the treatment of an existing cervical or uterine infection. The most satisfactory treatment for chronic cases is vaccines. The urine should be examined culturally as well as microscopically. Pregnant women should have their urine examined both for bacteria and for albumin.

Letters to the Editor.

A FALSE IMPRESSION

NEW YORK, *April 7, 1924.*

To the Editor:

I note in your last number a reference to "the late Dr. George Henry Fox" and am curious to know who he was. He must have been a very modest and retiring person since during the fifty years and more that I have lived in New York I have never known any doctor here, other than myself, who claimed that name.

Mark Twain once said that the report of his death had been greatly exaggerated. I am sorry that he ever said it as I have grown tired of hearing it repeatedly quoted as a new and up to date joke. But now I can appreciate his feelings as I am still alive, or at least imagine that I am, which is perhaps the next best thing. I do not always feel as lively as I did in years gone by but I still go to my office every day and would add (if I thought you would not blue pencil it) 114 East Fifty-fourth Street, office hours, 11 to 1.

I have plenty of spare time there, am always pleased to see old friends, and would be especially glad to welcome the writer of the reference quoted above and to learn whether he is able to make a diagnosis between me and my ghost.

GEORGE HENRY FOX.

THE PHYSICIANS' HOME, INC.

NEW YORK, *April 7, 1924.*

To the Editor:

The enclosed letter should be of interest to physicians. Its publication will enable your readers better to judge of the work being done. No doubt many will feel it a privilege to contribute to this most worthy cause.

MAX EINHORN.

CANEADEA, N. Y., *April 3, 1924.*

Max Einhorn, M.D.,
Director Physicians' Home, Inc.,

On March 1, 1924, The Physicians' Home had been in active operation two years.

During this period we, as a board, have worked hard and have made good progress when we consider we have worked with a limited capital. I feel it my duty to report at this time what has been accomplished during these two years under your directorship.

Farm house completely done over on entire inside with beaver board and decorated. Hardwood floors and trim throughout and finished natural.

Fireplace and chimney installed in spacious living room.

Kitchen made practical and convenient with cupboards and lighting.

Four bathrooms equipped complete with required amount of light.

A fully equipped laundry in the basement eighteen feet by thirty-six feet with concrete shutes to laundry from first and second floors.

Acquisition of three acres of woodland with sixteen foot right of way from highway.

Installation of vapor heating system furnishing adequate heat in the coldest weather. This is equipped with hot water attachment for laundry, kitchen, bathrooms, and two assembly rooms.

Kitchen and all rooms except four bedrooms furnished with good standard type of substantial furniture, fixtures, pictures, and hangings. We are a little short of rugs.

The addition of eight new rooms, furnished, heated and lighted and finished in walnut stain and varnish. Floors natural. These rooms each contain a standard lavatory.

The erection of lower and upper porch facing south, size nine feet by forty feet. Lower porch cement construction and equipped with chairs and lounges.

Back porches and walks cement construction.

Drives stone base and cinder topped.

Water system piped to barns, mill house, poultry house in addition to main building.

Erection of concrete dam makes an artificial lake one hundred feet by two hundred feet, average depth four feet.

An excellent radio outfit sufficient to receive from all stations.

One good type Victrola with one hundred records.

One Delco electric lighting plant, which has been sufficient for our needs so far and which has given good service.

One Ford truck, with which we deliver our milk, does station duty, and carries supplies.

The carrying on of our farm, dairy and fowl industry, which went a little on the red side the first year, but which furnished all products, vegetables, milk, eggs, fruit, and meat, and which, although not developed to the nth power of agriculture, has shown a profit this second year.

Orchards have been renewed and fifty new trees added.

During these two years we have served eight physicians. We have so improved one physician in health that he has been able to return to active practice. Our guests we have served have been deserving and appreciative.

One of the important points I wish to make is this. Every doctor who has been a guest has improved in health in this altitude of 1900 feet. Dr. A. came here a feeble old man, now he steps lively. Dr. B.'s mental trouble was practically cured at The Home. Dr. C. became mentally and physically able to resume his practice. Dr. J. has become able to work and is active where formerly her back was so weak she was able to walk but very little, and let me state right here that this doctor has earned the right to be called the mother physician of The Physicians' Home and should be so recognized by the board.

We have been fortunate in the selection of managers and have now a very worthy manager and matron who are interested in the work. Both are efficient, economical, and above all kind, and home makers.

To run The Home and provide for these two years and to accomplish and pay for the above we have spent approximately $25,000. This represents the allowance from the board and includes the income from the farm products.

Our permanent improvements are finished and we are equipped to serve twenty guests. Our first unit is practical and ready to serve.

This year we will have working with me the officers of our local society, who will meet at regular intervals in the interest of the Home in the hope that we can give increasing service and efficiency to the central board.

While the past two years has been hard on our treasury and our efforts have been toward making a presentable unit, in fact we have been going through the constructive period. Our permanent improvements are finished and we are now ready to run normal.

To do all these things has taken time, patience, money, judgment, and a little bit of courage. The directors have helped greatly in visits and letters of support and guidance and especially in this connection I must mention the good ideas and help rendered by the other members of the House Committee, Dr. Dieffenbach and Dr. Waldo.

To those members of the board who have been behind me one hundred per cent. let me extend my sincere thanks and appreciation. To those who have criticized me, please let me state that I have done my best, that I have no apologies to offer and that I am always ready to give a better man a chance at my job, whom I assure you, will have my best support.

Feeling that there is no greater work that any of us can do than to work for the cause of The Physicians' Home, also knowing that all the profession wants is a personal appeal and request rather than a mail appeal to make our treasury boom (we all know what happens to most of our mail appeals). Let us leave the middle of the stream and "Carry the Message to Garcia."

I want to say that I, as one director, feel it my duty to the cause and to the profession to help make this personal appeal possible and in support of this last statement will say that to start the "pot a-boiling" I will be one of the 250 men who will give $1,000 each to the support of The Physicians' Home Treasury.

STEPHEN V. MOUNTAIN, M.D.

Medicolegal Notes.

AGREEMENT BY SELLER OF PRACTICE NOT TO PRACTISE, LIMITED AS TO SPACE BUT NOT AS TO TIME, HELD VALID

In an action by one physician against another to restrain the defendant from practising medicine in Schertz, Texas, or within a radius of twenty miles thereof, in violation of a contract reciting that the defendant having sold his property in Schertz and his good will for a valuable consideration to the plaintiff, "agrees not to practice medicine in Schertz or within a radius of twenty miles of Schertz," it appeared that on the sale the defendant "moved and remained away, but he recently returned and began the practice of medicine in Guadalupe County, within the prohibited distance."

The principal feature of this case was that the prohibited territory was limited, but the time was not, and the question was whether the agreement was reasonable or unreasonable.

"Such a contract," said the Texas Court of Civil Appeals, "is not to be regarded as unreasonable, when fairly and openly made, nor in restraint of trade. The good will of a professional man may be as much an asset and a thing to be sold as that of a merchant.

"Whatever the strict rule of the common law may have been in condemning contracts in restraint of trade, such doctrine is much modified in America, and is not ordinarily made to apply to the contracts of professional men, skilled artisans, or purchasers of goods and merchandise, and the good will appertaining thereto, and binding the seller not to engage in the same business for a certain time limit and within a specified radius.

"It is not apparent why it is unlawful for a physician, if he can get any one to purchase his property and his good will, to do so, just as a merchant may do the same thing, and bind the seller not to further engage in the same business within a certain distance or radius.

"We see no reason whatever to hold broadly such a contract void. It is a property right, personal in its nature, and should be left to the liberty and freedom of contract. There is no such public policy involved in it as would require the physician to keep his good will for his own interest or restrain him from abandoning his practice and selling out his estate and good will together. Such a sale is contractual and thereby lawful."

In the case of Wolff v. Hirschfield, 23 Tex. Civ. App., 670, decided by the same court, such a contract where the time limit was fixed at twenty years was held valid.

The court here found no difficulty in agreeing with the trial court that a twenty mile radius is not unreasonable or greater than was necessary to guard the purchaser if he needed such protection in the pursuit of his business or profession. So far as the public was concerned, it was not likely to be hurt by such an agreement, since every other physician or surgeon of equal competency is at liberty to practise the same profession within the same limited territory.

The next question was, did the fact that the seller, the agreement being without time limit, contracted and bound himself never again to practise his profession within that territory render the contract a nullity as against public policy?

The court held that it did not. It said: "If one has the right to make a contract binding himself not to practise his profession for a great number of years, in a large or limited area, why not be allowed to make the same contract permanent, or at least during the life of the purchaser? What interest has the public in a professional man, that would deny to him such liberty of contract." It cited Glover v. Shirley, 169 Mo. App. 637; Davis v. Mason [Eng.], 5 T. R. 118; Presbury v. Fisher, 18 Mo. 50, and Webster v. Williams, 62 Ark., 101, as sustaining the validity of such contracts.

The court deduced from the authorities that contracts of the class under discussion, designated as restraints of trade, are void when unlimited, both as to time and space. They are valid if not unreasonable as to time or space. Here the space was limited, but the time was not.

The seller did not in his pleading attack the agreement on the ground of fraud or mutual mistake. It was a written contract, separately entered into, and the court suggested that the better course is, as a matter of practice, to reduce all such contracts to writing separately, as was done here, and not to burden title papers therewith, in which subsequent purchasers would have no concern. It was clear, however, from the testimony, that the agreement was a part of the consideration of the trade, and merged in the latter contract.

Judgment for the plaintiff was affirmed. Randolph v. Graham (Tex. Civ. App.), 254 S. W., 402.

EVIDENCE OF DEATH OF ANOTHER UNDER ANESTHETIC NOT ADMISSIBLE AS "SIMILAR INSTANCE"

In an action for damages for the death of a ten year old girl, alleged to have been caused by the negligent use of chloroform as an anesthetic while the defendant inserted three stitches in a small wound on the child's right thumb, the defendant's contention was that the death was due to the presence in the body of the deceased of an abnormally enlarged thymus gland.

A medical witness for the defendant was permitted by the trial court to testify to an examination of the body of a thirteen year old girl, who had been brought to a hospital for the removal of enlarged tonsils and adenoids, and to state that her death "was due to syncope under the influence of a general anesthetic administered for surgical purposes in the presence of a fifty gram thymus gland." The Massachusetts Supreme Judicial Court holds, Biancucci v. Nigro, 141 N. E. 568, that the defendant's contention that evidence of this collateral fact was admissible as a "similar instance" could not prevail. The court said: "An inference that the death of the plaintiff's intestate was due to the influence of chloroform in the presence of a thymus gland weighing fifty-one grams, or about one and two thirds ounces, could not properly be drawn from the mere fact that another child, of thirteen years, with a fifty gram thymus gland died from the influence of a general anesthetic administered for surgical purposes. It does not appear that the conditions or circumstances, such as the health of the child, the amount of anesthetic administered, and other conditions affecting the result, were the same in the illustrative case and in the case in hand."

An exception to the evidence was therefore sustained.

CROSS EXAMINATION OF MEDICAL EXPERTS AS TO MEDICAL TREATISES

In a personal injury case objection was made to the questioning of medical experts for the defendant concerning their familiarity with certain treatises, their authority, and as to how the witness' views corresponded with the views therein. The Texas Court of Civil Appeals, Fort Worth & R. G. v. Woodward, 254 S. W. 227, holds that such evidence is permissible on cross-examination of a medical expert testifying for the opposite side "to test the knowledge of the socalled expert and to determine the weight of his testimony."

The Effects of Removal of Dental Infection on Chronic Gastrointestinal Disorders*

G. REESE SATTERLEE, M.D.

New York

Focal infection as an injurious factor in the human mechanism has been discussed widely and from many angles. Probably because of the incompleteness of the studies forming the basis for certain communications regarding this important form of infection, which the English writers refer to as subinfection or medical sepsis, it has often been discounted or made light of. Complete systemic studies of the foci, especially in their relation to the disorders of the gastrointestinal tract, are essential for a proper recognition and treatment of these conditions. The injurious effects of the dental foci as causative agents in diseases of the heart, joints, kidneys and vessels are now generally recognized, but the farreaching effect of oral infection upon the gastrointestinal tract is frequently underestimated or overlooked. It is true that clinicians have long known that gastritis or gastroenteritis have borne a close relationship to socalled bad teeth, but even this limited knowledge has been casual and not based upon the exact scientific studies which characterize medicine today.

May I emphasize at the beginning that it would be a gross error to ascribe more than their just proportion of the troubles of chronic intestinal invalids to infected teeth alone. A very large percentage of these patients present not only infected teeth but many other areas of streptococcus and colon bacillus infection as well. It is a matter of the greatest importance to all clinicians that the sick individual should be surveyed from the viewpoint of the whole rather than of the separated parts of his anatomy. This viewpoint is beginning to have general recognition and is, I believe, a wholesome reaction against the continuance of the isolated specialization of the past two decades. It implies a much closer bond than has heretofore existed between dentistry and medicine. There occur, therefore, in the cases herewith presented, a few instances only in which infected teeth have constituted the sole findings, and in which thorough eradication of these restricted foci has resulted in satisfactory improvement. In following this synthetic trend toward unification in the differential diagnosis and treatment of chronic invalidism, we have been impressed in a recent study of 1,512 patients, with the following generalizations:

1. That discouragingly persistent poor results were often noted after abdominal operations for ulcer, appendicitis, cholelithiasis, peritoneal adhesions and pelvic conditions, in all of which conscientious postoperative medical care was given, but in which no attention was paid to oral sepsis.

2. That satisfactory and permanent results ensued in the past three years in a similar class of patients in whom all obvious foci, oral and otherwise, had been removed prior to abdominal operation.

3. That in a rapidly growing group of patients, presenting definite classical symptoms of gastric and duodenal ulcer, cholecystitis, gastroenteritis and colitis, these symptoms have subsided after a thorough surgical removal of all obvious foci of infection.

It is not in the province of this paper to discuss the difficult problem of the occasional substitution of the surgical removal of oral and other obvious infections for socalled radical abdominal operations, because there has not yet been time enough to analyze a group. It may well be that such abdominal operations, which in certain instances have been rendered at least temporarily unnecessary, will ultimately be required in order to maintain the full restoration of health. It is not yet understood to what degree oral sepsis is actually the primary factor in cases presenting serious abdominal symptoms; many such symptoms may be the result of referred pain. It is only by continued study and the passage of time that these problems can be solved, and one of the main objects of this paper is to report our findings to date upon this important point.

It is evident that the experimental work of Rosenow, Moody, Henrici, Bumpus, Meissner, Goadby, Thoma, Upson, Hunter and many others on focal infection dovetails more and more closely into our clinical studies as each of these important branches of medicine becomes more advanced. As accuracy and standardization in methods of studying this intricate problem are much to be desired, I would lay especial emphasis upon the following points.

*Read before the Section on Stomatology, American Medical Association, June, 1923.

SINUS INFECTION

The sinuses of the head most frequently infected among chronic intestinal invalids are the antra. In all cases the acute sinus infections are to be disregarded as outside the present purpose of this study. The antra may present all degrees of chronic infection from an ordinary proliferative change in the mucous membrane to an extensive and highly destructive osteomyelitis of the antral wall. The fact that the long controversy as to the best methods of surgical approach and therapeusis of the antrum is still undecided shows that the matter is not settled. Where this is due to the spread of infection from the diseased area about a tooth, the logical surgical procedure would be to attack the antrum through the alveolar process, as it is obvious that the area of infection must be cleaned up. In our experience the bulk of these chronic antrum infections are of dental origin. While there are many operations and methods of dealing with chronic infected antra, we feel that the first and most necessary procedure is to eliminate the dental infection. While this infection persists, we feel that no form of treatment or operation, however cleverly devised in its mechanical inception, will produce a cure.

My associate, Edward S. Pope, recommends the following sequence of procedure in dealing with infections about the head; First, removal of tonsils; second, removal of teeth; and third, such operations as may be necessary for drainage or direct treatment of the sinuses, a reasonable interval being allowed between the steps. If the tonsils are infected there is bound to be a continuous flow of germ laden air from the nasal passages and sinuses on sneezing, blowing the nose forcibly or coughing, and infection may be forced to the furthermost areas. An illustration of this is seen in the acute middle ear conditions so often arising from this cause.

PATHOLOGICAL STUDIES

The conditions usually encountered in and about the teeth are abscesses, granulomata, apical absorptions, cysts, pericemental and alveolar absorptions, pyorrhea pockets, and osteomyelitic areas. The most frequent lesion of the sac type found in our experience is the cyst. This probably originates from an acute abscess which has not been drained or from a chronic abscess verging into a granuloma and finally becoming cystic. The evidence of these lesions is shown most effectively by the x ray. Many teeth appearing normal under the physical tests show degeneration on the films. It is necessary, therefore, to have a complete x ray study of all the teeth. Apical absorption is frequently the only evidence of infection and these teeth should be extracted. The argument is frequently advanced that all these conditions may be present without symptoms, either general or oral, and that, therefore, they should be disregarded. This, however, is not a logical stand, for we have observed many patients in whom these conditions have existed for years before definite recent symptoms, proven to be due to them, have occurred.

Teeth that have been devitalized, either by accident or by election, are somewhat loosely spoken of as dead teeth. Undoubtedly the technic of removing nerves from the root canals, followed by filling, has led to many serious infections. It is equally probable that socalled dead teeth may exist without infection, but as the devitalized tooth has become to a large degree a foreign body, liability to infection is always present and increased. If such teeth are not extracted they should at least be watched carefully and x rayed every six months. In our experience we have found that the hollow metal crowns and Richmond crowns and pivots nearly always harbor serious infection.

SYMPTOMATOLOGY

Absence of pain is the most important clinical phenomenon. It is characteristic of streptococcus infection. Its importance cannot be overestimated. Draper has discussed this in detail. Discomfort may be present but actual pain, if present, is almost certainly to be an indication of a mixed infection. Another indication is the frequency of a peculiar metallic taste which may be caused by the action of the bacteria or their products upon metal.

Both from a clinical and cultural viewpoint the question of the removal of teeth presenting mild grades of infection is an important one. We believe that it should not be decided by the dentist alone or by the internist alone but by evidence based upon their respective findings. The systemic condition of the patient affords invaluable aid in reaching a decision.

Recognition and appreciation should be given to all the members of our group for their cooperation in the accomplishment of these clinical studies. These men are John W. Draper, Edward S. Pope, Redford K. Johnson and Ferdearle Fischer. Daniel E. Drake has been of great assistance in the care and follow up of the patients in his sanitarium. The cases contributed by Dr. Drake have been labelled with the letter D.

RESULTS OF BACTERIAL CULTURES

CULTURES FROM APICES OF 133 EXTRACTED TEETH

Streptococcus mitis.....	65	Streptococcus pyogenes..	8
Streptococcus salivarius.	56	Streptococcus equinus...	6
Streptococcus anginosus.	24	Staphylococcus albus....	23
Streptococcus fecalis....	11	Staphylococcus aureus...	5

CULTURES FROM NECROTIC BONE AREAS

Streptococcus mitis.....	13	Streptococcus pyogenes..	3
Streptococcus salivarius.	9	Streptococcus fecalis....	1
Streptococcus anginosus.	6	Staphylococcus albus....	8
Streptococcus equinus...	2	Staphylococcus aureus...	1

CULTURES FROM ANTRA DIRECTLY ON OPENING THROUGH MOUTH

Streptococcus mitis.....	14	Staphylococcus albus....	21
Streptococcus salivarius.	10	Staphylococcus aureus...	3
Streptococcus anginosus.	4	Mucosus capsulatus.....	1
Streptococcus pyogenes..	5		

The bacteria have been cultured and differentiated according to Holman's method. Of the streptococci, the Streptococcus anginosus and pyogenes are of the pathogenic hemolytic type, the others, mitis, salivarius, fecalis, and equinus are nonhemolytic. As a rule, when the hemolytic organisms were recovered the patient was distinctly ill.

CULTURES FROM INTERIOR OF EIGHTEEN TONSILS AFTER TONSILLECTOMY

Streptococcus mitis.....	13	Streptococcus fecalis....	4
Streptococcus anginosus.	13	Streptococcus pyogenes..	1
Streptococcus salivarius.	4	Staphylococcus aureus...	12
Streptococcus equinus...	3	Bac. pyocyaneus	1

TWENTY-ONE CULTURES FROM CERVIX UTERI

Bacillus acidi lactici	5	Streptococcus fecalis	3
Bacillus neapolitanus	3	Streptococcus mitis	2
Bacillus coli	2	Streptococcus salivarius	2
Staphylococcus	10	Streptococcus anginosus	1

It is of interest to note the appearance of the colon bacillus in this region and its absence in the tonsil.

NINETY-FOUR CULTURES FROM THE FECES

Bacillus acidi lactici	34	Bacillus Morgani	1
Bacillus neapolitanus	35	Streptococcus fecalis	14
Bacillus communior	31	Streptococcus mitis	7
Bacillus coli	25	Pyocyaneus	2
Bacillus dysenteriæ	5		

SUMMARY OF CASE HISTORIES

It is to be noted in a series of seventy-two cases that whatever the diagnosis might be the lesions and the nature of the infection are similar.

It is often extremely difficult to classify these cases according to diagnosis, because a lesion in one part of the body is frequently succeeded or accompanied by another in a different locality and the classic diagnosis is ruined.

The cases are divided into groups according to the chief symptomatology. It can be seen, however, that a toxic neurasthenic can be readily transformed into a chronic intestinal invalid, a psychotic, an epileptic or a cardiorenal case upon the slightest provocation. Frequently the symptoms of the nervous system are uppermost when the chief lesion is in the gastrointestinal tract.

No cases have been included in the table that have not had a thorough examination and treatment and a follow up of one year by personal contact. Unfavorable cases have been included and the reasons for failure explained as far as possible.

The treatment of all these cases has been along the same lines—the gradual removal of all foci and medical therapy aided by enteroantigen and serum.

Some of the apparently hopeless cases, such as advanced arthritis, toxic neurasthenia, hemicrania and cardiorenal cases, have been remarkably improved after the removal of foci.

In Case No. 4383 the patient had had two abdominal operations for perigastric adhesions, hour glass stomach, with persistent abdominal pain. The cause of this pain, which was a referred pain, originated from a dental infection. The pain was not relieved until five years after the last laparotomy when the dental infection was discovered and removed.

Head infections.—Where the sinus infections have progressed to a chronic pansinusitis, the prognosis is usually bad, as in cases 5042 and 4467.

Arthritis.—Three cases of arthritis, Nos. 3762, 4561 and 4867, were very far advanced but the joint infection was controlled by these methods.

Tertiary syphilis.—Cases 4277 and 4448 illustrate the benefit of the removal of foci in tertiary syphilis. Case No. 4277 was of syphilitic myocarditis, hepatitis and nephritis, which made some improvement under antisyphilitic treatment but did not show lasting benefit until the dental infection was removed.

Epilepsy and syphilis.—No. 4448, a case of epilepsy, showed no improvement of the epileptic condition under antisyphilitic treatment but the patient recovered after resection of the entire colon and removal of oral foci.

Blindness.—Case 3987 merits special notice. All the patient's teeth had been extracted thirty years ago. There were progressive iridocyclitis and secondary glaucoma, with almost total loss of vision, and there were also undoubted signs of cholecystitis. Osteomyelitic areas in the superior maxillæ with diseased antra were thoroughly curetted and a permanent result in improved vision and cessation of abdominal symptoms obtained.

Hemicrania.—These cases may give even more spectacular results than are shown on the chart. The symptoms are evidently due to the toxemia from focal infection and usually the colon is badly diseased, so that colectomy may be indicated.

Cardiac arrhythmia.—Cardiac irregularities, with or without fibrillation, are usually benefited by the removal of foci. One case only is reported, but this condition may appear at any time in other instances.

Asthma.—The early recognition of gastrointestinal asthma is imperative, because the changes in the bronchial tract may become permanent. Three cases with satisfactory results are recorded.

Toxic psychosis.—The results in the seven cases reported are very satisfactory, but the prognosis is not so good when the condition has lasted over three years. Prepsychosis, dementia precox and manic depressive insanity are illustrated. Sudden acute mania shows the most satisfactory results.

Arteriosclerosis.—As arterial changes are indicative of advanced infection, these cases should be treated early.

Gastric and duodenal ulcers and cholecystitis.—These conditions need surgically clean mouths, as illustrated by the improvement in three cases of duodenal ulcer and two of cholecystitis. Many of the patients have undoubtedly had cholecystitis but were not classified under this heading.

Toxic nephritis.—Cases No. 4056, 4801 and 4178 show severe nephritis with hematuria, the most prominent symptom. Pure cultures of the colon bacillus were obtained from the urine by ureteral catheterization. As hematuria was the most pronounced symptom a hemolytic streptococcus infection of the kidney with a secondary implantation of the colon bacillus was considered most likely. All three of these patients responded well to surgical removal of foci and enteroantigen therapy.

Nephrectomy was necessary in one case on account of urinary suppression on one side and pure blood in the ureter.

SUMMARY

1. All conditions classified as chronic intestinal invalidism need an exhaustive study for medical infection, otherwise known as focal infection.

2. Mouth infection, if not the primary source, is the most frequent and important seat of infection.

3. No one focus can be considered alone but the whole body carefully examined for obvious foci.

4. Complete surgical eradication of minor foci before major abdominal surgery is considered; if impracticable, postoperative removal of these foci.

5. The importance of bacterial studies and treatment by enteroantigens.

6. Our aim should be prevention, therefore removal of all foci, however small, before permanent changes in other parts of the body may occur.

CHRONIC INTESTINAL INVALIDISM

Case No.	Sex	Age	Complaint	Duration Years	Lesion	Treatment	Result	Remarks
6499	F	41	Painful hemorrhoids; constipation	1	Infected hemorrhoids; infected cervix and cysts; infected teeth, granuloma; previous appendectomy.	Surgical removal of all foci.	Recovery	
4383	F	37	Perigastric adhesions; hour glass stomach; pericolic adhesions; epigastric pain	7	Hour glass stomach and pericolic adhesions; infected and impacted teeth; chronic maxillary sinusitis; ethmoiditis; infected tonsils; cervicitis.	First operations severing adhesions; 5 years later surgical removal of foci except cervix.	Improvement	Cervix not enucleated. Pain not relieved until oral foci removed.
4653	M	61	Chronic intestinal invalidism with ocular symptoms and hemorrhoids	16	Infected teeth, granuloma; chronic maxillary sinusitis with polypi; necrosis; pericolic adhesions and reduplication of left side and stasis.	Surgical removal of oral foci.	Recovery	Abdominal operation seemed inevitable at first, prolonged case, excellent result.
4281	M	28	Toxic neurasthenia		Pericolic adhesions and stasis; infected teeth and antra; osteomyelitis.	Medical treatment vaccines; resection of colon; later, surgical removal of oral foci.	Recovery	Three years period between colectomy and surgical removal of oral foci. Patient says latter gave him most benefit.
D-5262	F	34	Acute appendicitis with gastric irritability with vomiting	7	Acute appendicitis; spasmodic contractions of stomach with two gastroenterostomies; infected tonsils; infected teeth; perinephritic abscess; chronic maxillary sinusitis.	Appendectomy; gastroenterostomy, 1; gastroenterostomy, 2; tonsillectomy; surgical removal of dental infection; perinephritis abscess drained; operation for maxillary sinusitis.	Very marked improvement	No permanent relief from operation until extraction of infected teeth and opening of antrum, then immediate and steady.
4371	M	49	Dysentery, bloody stools and gas	20	Dilated colon; pericolic adhesions; infected teeth; chronic maxillary sinusitis.	Surgical extraction; surgical removal of foci; vaccines.	Marked improvement	Principal complaint of flatulence relieved; bowels all right.

HEMICRANIA

3789	F	44	Hemicrania; constipation.	17	Cecal colon stasis one hundred hours; cecum mobile; later, infected teeth, chronic maxillary sinusitis; infected tonsils.	Resection of ceco-colon; surgical removal of local foci; vaccines.	Recovery	Recovery not complete until removal of focal infection.
5084	F	36	Hemicrania and constipation	7	Infected teeth, infected tonsils and colon; pericolic adhesions.	Surgical removal of foci (teeth and tonsils); serum treatment; partial resection of colon.	Recovery	
4898	F	38	Hemicrania; constipation; neurasthenia	30	Appendicitis; infected tonsils; painful coccyx; infected cervix; ulcer of rectum; infected teeth; chronic maxillary sinusitis.	Appendectomy; tonsillectomy; removal of coccyx; enucleation of cervix; surgical removal of teeth; surgical removal of antral infection.	Recovery	No permanent result until infection in cervix and mouth were removed.
4941	M	42	Hemicrania; constipation	5	Infected tonsils; infected teeth and cyst; alveolar absorption.	Surgical removal of foci (teeth and tonsils).	Recovery	Marked improvement in constipation.

ASTHMA

4207	F	39	Asthma and constipation; chronic intestinal invalidism.	10	Infected tonsils; hemorrhoids; pericolitis and stasis.	Surgical removal of foci (tonsils and hemorrhoids); colon strep. vaccines and serum.	Marked improvement	
4363	F	70	Asthma	50	Chronic appendicitis with pericolic membranitis.	Appendectomy and separation of bands.	Marked improvement	Intervals of remission.
D-5146	M	12	Asthma	11	Chronic appendicitis.	Removal of gangrenous appendix.	Marked improvement	Fulminating ganglion appendix; oblige operation which had been refused several times.

TOXIC NEURASTHENIA

3746	M	48	Toxic neurasthenia.	1	Retained filling after extraction of molar; apical absorption of one tooth.	Surgical removal of one focus of retained filling.	Recovery	No other treatment.
4548	F	30	Toxic neurasthenia; intestinal invalidism.	20	Enteroptosis; infected teeth; infected tonsils.	Surgical extraction of infected teeth and removal of tonsils. Medical treatment (support and posture, vaccines).	Partial recovery	
4594	F	32	Toxic neurasthenia; intestinal invalidism.	3	Infected teeth and tonsils; hemorrhoids and proctitis.	Removal of infected foci; abdominal support, posture, diet and colon vaccines.	Recovery	
3954	M	38	Toxic delirium and neurasthenia.	3	Infected teeth, chronic maxillary sinusitis; infected tonsils; duodenal ulcer.	Surgical removal of foci; serum and vaccines.	Slow recovery	Marked cutaneous hyperemias and urticaria; slow but good result.
3942	F	48	Toxic neurasthenia; intestinal invalidism.	7	Chronic appendicitis; infected teeth; chronic maxillary sinusitis; proctitis.	Surgical removal of foci; appendectomy.	Recovery	One year later acute nephritis and recovery.
4296	F	45	Toxic neurasthenia.	2	Infected teeth; chronic maxillary sinusitis; proctitis.	Surgical removal of foci, especially antrum; later tonsillectomy.	Slow recovery	Tonsils appeared normal but showed small deep seated abscess.

Case No.	Sex	Age	Complaint	Duration Years	Lesion	Treatment	Result	Remarks
					TOXIC PSYCHOSIS			
3817	M	30	Mental instability; dementia precox	5	Infected teeth and tonsils; infected colon; pericolic adhesions.	Removal of foci; partial resection of colon.	Improvement.	Testicular implants.
4490	F	33	Toxic psychosis	10	Previous appendectomy; multiple foci; ovaries; cervix, hemorrhoids; infected colon.	Surgical removal of all foci; total colectomy.	Complete recovery	One year after.
D-3976	F	24	Prepsychosis	1	Enteroptosis; infected teeth; hemorrhoids; infected cervix; chronic maxillary sinusitis.	Surgical removal of all foci.	Recovery	Infected cervix in young girl; no results until antrum operation.
D-5073	F	38	Acute mania	7	Infected teeth, cervix and tonsils; chronic maxillary sinusitis and impacted molar.	Surgical removal of all foci.	Recovery	Condition fine six months after.
D-4270	M	8	Dementia precox early.	6	Infected colon and tonsils; intestinal stasis.	Tonsillectomy; partial colectomy.	Recovery	Incorrigibly suicidal and homicidal; constipated from birth. Honor boy at high school.
D-3892	M	49	Manic depressive insanity	4	Infected tonsils; chronic maxillary sinusitis.	Tonsillectomy; surgical removal of mouth foci.	Recovery	No improvement from tonsillectomy but recovery complete after operation on antrum.
					ULCERS			
4466	M	43	Duodenal ulcer; appendicitis	2	Duodenal ulcer; subacute appendicitis; infected teeth, impacted wisdom tooth; chronic maxillary sinusitis.	Appendectomy and gastroenterostomy; later surgical removal of foci.	Recovery	Recovery not complete until after dental extraction.
4092	M	39	Duodenal ulcer; appendicitis.	15	Duodenal ulcer and appendicitis; previous dental extraction; intestinal stasis.	Gastroenterostomy and appendectomy; diet and vaccines.	Recovery	Good results aided by previous removal of oral infection.
4173	M	52	Duodenal ulcer	18	Duodenal ulcer and diverticulum; infected teeth.	Gastroenterostomy; later surgical removal of oral foci.	Recovery	
					CHOLECYSTITIS			
3934	M	53	Cholecystitis	4	Cholecystitis, jaundice; infected teeth; infected tonsils; chronic maxillary sinusitis.	Surgical removal of oral foci-colon vaccines.	Recovery	Excellent condition two years later.
5042	F	46	Cholecystitis; constipation; headache.	6	Cholecystitis, jaundice; infected teeth; necrosis; chronic maxillary sinusitis; proctitis; pansinusitis.	Surgical removal of all foci; cholecystectomy.	Slight improvement	Incurable invalid.
					KIDNEY CASES			
4056	M	61	Hematuria	20	Hematuria, both kidneys (colon bacillus infection); infected teeth; chronic maxillary sinusitis.	Surgical removal of foci; colon vaccines.	Marked improvement	Hematuria ceased almost immediately; recurred, but controlled by colon vaccines.
4801	M	45	Septic fever; colon infection of kidney.	3	Pyelonephrosis; pure culture of Bacillus communior in urine; infected tonsils and teeth; chronic maxillary sinusitis.	Medical, cystogen; serum and vaccines; surgical removal of foci.	Recovery	Hematuria occurred temporarily after removal of teeth and tonsils.
4178	F	47	Hematuria	1	Multiple abscesses of kidney; hemorrhagic nephritis; infected teeth; chronic maxillary sinusitis.	Previous surgical removal of mouth infection; nephrectomy; vaccines.	Recovery	Bacillus coli still present in urine one and one half years after; no symptoms.
					MISCELLANEOUS			
4277	M	41	Syphilitic heart and liver. Aortic lesion.	7	Syphilitic myocarditis; hepatitis; infected teeth; chronic maxillary sinusitis; infected tonsils.	Antisyphilitic, five years; then surgical removal of foci—teeth and tonsils.	Marked improvement	Wassermann four plus continually in spite of antisyphilitic treatment; reduced to one plus after removal of infected foci.
4069	F	18	Toxic cardiac arrhythmia.	3	Irregular heart (no organic lesion); dilated cecocolon; infected and impacted teeth; infected tonsils.	Removal of foci; colon vaccines.	Improved	
3836	M	46	Cardiospasm	7	Infected teeth; supernumerary tooth; chronic maxillary sinusitis; osteomyelitis.	Surgical removal of infected foci.	Recovery	
3953	F	59	High blood pressure.	2	Infected teeth; nonerupted molars; chronic maxillary sinusitis and polypi; intestinal stasis.	Surgical removal of foci; diet.	Recovery	Blood pressure became normal.
4477	F	43	High blood pressure; retinal hemorrhages.	7	Infected teeth; infected tonsils.	Removal of tonsils—not of dental foci.	Marked improvement	Previous medical treatment of no avail; blood pressure and symptoms relieved.
4009	F	23	Blindness; goitre	2	Infected teeth; retinal hemorrhages; chronic infected tooth; medical nephritis; infected tonsils.	Surgical extraction of treatment.	No improvement; death	Advanced case.

Myocardial Insufficiency as a Primary Factor in the Causation of an Asthma Complex*

M. MURRAY PESHKIN, M.D.
New York

The purpose of this communication is to bring to the fore and emphasize a symptom complex which I have termed primary myocardial insufficiency asthma complex and which I believe is an important clinical entity. The early as well as the late stages of this complex, especially the asthmatic state have in my experience been readily mistaken for other diseases. I therefore feel that any observation that will aid in the recognition of this syndrome is worthy of record.

In a review of sixty-two patients with asthma, twenty of whom were over forty and the remainder over fifty years of age, careful studies were made to determine the etiology. Of the total number, fourteen sought relief from asthma in spite of repeated failures to get relief from various medical and other forms of prescribed treatment. These fourteen cases fell into the category of primary myocardial insufficiency asthma. Some of these fourteen patients have been tested thoroughly by the scratch and intradermic methods to determine possible protein sensitization. Personally I consider these attempts futile and unnecessary, because protein sensitization does not enter as an etiological factor in the causation of this symptom complex.

It is surprising how frequently, in patients suffering from asthmatic symptoms, the direct connection between these symptoms and various forms of cardiac disease is overlooked. In some cases of bronchial asthma or asthmatic bronchitis of sufficiently long standing a myocardial insufficiency develops and is directly due to the heart strain induced by the primary condition. Our subject, however, deals with a myocardial insufficiency in which the asthmatic symptoms are secondary. In the advanced stage of this condition, cardiac failure is obvious and is then easily mistaken for the socalled cardiac asthma which as will be shown later, is an altogether distinct and different clinical entity. It is essential to know whether or not the myocardial insufficiency is primary or is secondary to the asthma, for the management and prognosis of the case is entirely different in these two conditions.

Myocardial insufficiency is a common condition but unfortunately it is not commonly recognized in its early stages. The importance of this fact has been recognized by many cardiologists and has been stressed recently in their writings.

Greene (1) maintains that failure to appreciate the large proportion of deficient hearts is common. This type of heart though diseased is not the seat of endocarditis or of frankly expressed myocardial inflammation or degeneration; its signs and symptoms are wholly or relatively silent. There is also "a general failure to recognize subjective symptoms of persisting myocardial inadequacy and reserve impairment such as constitute a most important factor of evidence of this condition when existing in its minor but vital degrees."

Thayer (2) and Wiggers (3) hold that a diagnosis of early myocardial insufficiency may be made before anything abnormal can be detected on examination of the heart and a positive diagnosis of cardiac disease may be made from the history alone, based on a careful study of the sensations of patient, on the relation of one symptom to another, and on the gradual increase and severity of the symptoms.

If one glances through authorative textbooks, valvular diseases are described in minute detail, but as Christian (4) states, "there rarely appears a clear description of a common cardiac disorder in which the fault is primarily in the muscle and the valves themselves are normal. In just the same way the textbooks of pathology fail to give any definite satisfactory description of this common type of cardiac lesion, probably because very often the heart muscle and the coronary system present no lesion that the pathologist can describe in objective terms."

It is to the great credit of Sir James Mackenzie who was one of the first, if not the first, to advocate the study of cardiac disease by learning something of its early symptoms before physical signs become apparent. He has taken great pains to point out the importance of going into the minute details of the patient's recollection of the onset of his condition. Mackenzie (5) states that "if one takes any of the chronic diseases and ask what we know about their onset and early symptoms, we will find that there is in our knowledge a great defect. From this point of view the symptoms present in the early stages have been practically neglected. Often the secondary symptoms are so prominent that the patient's complaint is likely to be labelled by the most prominent symptoms of the late stage."

Neuhof (6) in a chapter dealing with decompensation states the subject succinctly by remarking that "when cough is due to bronchial congestion, the physical signs are the usual ones of bronchitis. In addition, rather marked sibilant breathing may be present, thus resembling bronchial asthma. The wheezing inspiration, however, is probably caused by the bronchial congestion and mucus in the bronchial tree and not from any anaphylactic reaction."

In dealing with the difficult problem of asthma with its various and multitudinous causes, the percentage of therapeutic failure is unfortunately large, in spite of the vast progress made during the past decade. Of the failures the largest number occurs in patients past fifty years of age. Early myocardial insufficiency as a primary cause of asthma directly affects these cases and its recognition will in a large measure reduce our percentage of failures.

ETIOLOGY

The etiology of primary myocardial insufficiency asthma is essentially that of chronic myocarditis with decompensation.

*Read before the Riverside Medical Society of the City of New York, December 18, 1923.

An intercurrent illness hastens the progress of the disease so that the asthmatic symptoms may first make their appearance during convalescence or soon after the usual activities are resumed.

It must be emphasized, however, that the existence of a myocarditis in itself does not predicate asthma.

SUBJECTIVE SYMPTOMS

Perhaps no organ of the body gives better subjective evidence of its functional integrity or impairment than the heart. In primary myocardial insufficiency asthma there is a group of subjective symptoms, the recognition of which is essential to an early diagnosis of this condition. Before asthmatic symptoms become evident, a careful history will elicit symptoms of beginning myocardial insufficiency. These are so subtle and so slight that they are likely to be overlooked or to be considered of relatively little importance. The patient at first notices that he becomes somewhat fatigued or slightly short of breath after some customary exertion which had not affected him previously; and if the patient persists in his exertions, the tendency to fatigue and breathlessness is increased, until finally his exhaustion does not respond as readily to rest as formerly. The rapidity with which these symptoms become sufficiently pronounced to demand attention on the part of the patient depends upon his occupation, temperament, environment and economic condition.

When the condition becomes more advanced, cough is an important factor. It is at first hard, hacking and unproductive, and is most troublesome towards the end of the day, more noticeable if the patient has been active. The cough is usually mistaken for a mild bronchitis. At first the cough will be relieved simply with rest. Later, the cough becomes aggravated and a feeling of tightness in the chest develops, usually accompanied by wheezing. Sleep becomes disturbed. The heart reserve is more and more encroached upon and finally fully developed asthmatic attacks result. The attacks come at irregular intervals, depending upon the degree and the period of myocardial exhaustion. Secondary infection takes place resulting in a subacute productive bronchitis which adds to the respiratory embarrassment. During this early stage the condition resembles bronchial asthma. Later, the cardiac reserve is completely exhausted and the rest force of the heart is encroached upon. The asthmatic symptoms become continuous. Sleep is possible for only short periods at a time, weakness and asthenia are marked. A vicious circle is established which further encroaches upon the rest force of the heart. Precordial pain may be complained of, at times characteristic of true angina pectoris.

Comparatively early in the course of the disease, edema of the ankles appears at the end of the day. It may be so slight as to escape attention. In advanced cardiac failure the degrees of edema though variable is always present.

In the late stages due to passive congestion of the viscera patients may complain of digestive disturbances and various epigastric and abdominal pains.

OBJECTIVE SYMPTOMS

When the patient first seeks advice he comes for the relief of his asthma. He has no suspicion of heart trouble nor does the physician suspect it. The slight heart signs that may be present are easily mistaken for secondary factors attributable to the patient's asthmatic state. Early in the disease a positive diagnosis from the physical signs alone can not be made with certainty. The overshadowing picture is that of asthma. In this early stage, the respiratory rate is usually slightly increased. When bronchial infection is absent, auscultation will reveal sibilant and sonorous râles, a few ronchi and perhaps a few crepitant râles at the bases of the lungs. These signs are found usually with both inspiration and expiration. Towards the end of the day the râles may be more numerous, respiration more labored, slight pallor or even cyanosis may be present.

On examination of the heart there may be or may not be some enlargement. The sounds lack normal muscular quality. The apex beat is soft and less forceful than normal. In this stage a murmur is not usually found. The pulse rate is always increased. This increased rate is particularly noticeable after rest. The range is usually from 80 to 90 a minute. Indeed, it may be said that a persistently elevated pulse rate which does not slow down after rest in an individual past middle age with onset of asthmatic symptoms as described, is almost pathognomonic of primary myocardial insufficiency asthma. In the early stages the pulse is regular and with the exception of the increased rate is practically normal. Upon exertion, recovery from the increased rate is much more delayed than normal.

As failure of the circulation progresses, the asthmatic symptoms become more pronounced and continuous. Complicating bronchitis and emphysema are always present. Crepitant râles are now persistent at the bases and are irregularly distributed throughout the lungs, particularly during the exacerbations of severe asthmatic attacks. Respiration is rapid, shallow and labored even at rest. Wheezing and respiratory oppression are continuous. Cyanosis may become so marked as to be of immediate concern.

During this advanced stage the heart, by percussion, is usually found to be enlarged first to the left and later to the right of the midline. A distinct systolic murmur at the apex is common. The murmur may or may not be transmitted to the axilla. The pulse rate is persistently increased, usually 120 or more beats a minute. There may be marked arrhythmia due to extrasystoles or auricular fibrillation. In this stage the picture of cardiac failure is obvious and is then mistaken for socalled cardiac asthma.

In this series of cases the degree of apparent and visible arteriosclerosis found was not more than to be expected for the age of the individual. Normal blood pressure or hypotension is the rule.

CARDIAC EFFICIENCY TESTS

Various methods have been proposed for determining cardiac function. But, Brittingham and White (7), Ulrich and Nathanson (8), among others, have reached the conclusion that there is at present no definite standard to determine myocardial insufficiency.

Peabody (9) and others have shown the correlation of cardiac dyspnea and vital capacity. In this

test the heart is studied as it expresses its balance or disbalance by physical changes brought about in the lungs. However, in cases of primary myocardial insufficiency asthma, especially in the presence of a complicating bronchitis and other lung changes, the vital capacity test becomes of doubtful value since these conditions muffle the interpretation of the vital lung capacity.

The electrocardiogram also is not an exact test for cardiac function. The information derived from it may be misleading for although certain changes (10) in certain leads may indicate a damaged heart muscle, it does not necessarily mean that there is impaired heart function or vice versa.

After all in early myocardial insufficiency, the most dependable means at our command to estimate cardiac function is a very careful investigation of the patient's history and symptoms.

DIFFERENTIAL DIAGNOSIS

Since primary myocardial insufficiency asthma has usually its onset past middle age, the diseases from which it must be differentiated are comparatively limited to certain types of asthma or conditions simulating asthma.

A typical picture of early primary myocardial insufficiency asthma is as follows: an insidiously progressive fatigue, dyspnea, cough, respiratory oppression, wheezing, ending in asthmatic attacks; nothing much evident upon physical examination except the typical asthma lung signs and a persistently increased pulse rate. The injection of epinephrin hydrochloride gives no relief. The administration of adequate doses of digitalis controls the cases so markedly that it is to a certain extent diagnostic.

In asthmatic bronchitis there is a definite history of acute or subacute respiratory infections before asthmatic symptoms make their appearance. These cases are protein nonsensitive. With onset over forty, the subjective symptoms characteristic of cardiac impairment are absent. The pulse rate is not increased during the intervals of freedom from asthma. The cardiac response to effort is good. When complicated by a secondary myocardial insufficiency and the circulation is restored, the asthmatic symptoms are lessened but not entirely relieved. Temporary relief is usually induced by injection of epinephrin hydrochloride.

Bronchial asthma with onset in a patient past forty, exhibiting protein sensitization, is uncommon. Walker (11), for example, found no case sensitive with onset after fifty. In the presence of sensitization, asthmatic attacks are closely associated with environment. A careful history can easily detect this type of asthma which is almost always caused by the inhalant group of proteins.

Hypertrophic emphysema with symptoms of secondary myocardial insufficiency complicated by bronchiectasis may produce symptoms simulating asthma. In these cases there is a previous history of chronic bronchitis with onset prior to the age of forty.

Advanced primary myocardial insufficiency asthma may be mistaken for cardiac asthma, which is at present a loose term applied to various conditions. Cardiac asthma applies to the type of nocturnal paroxysmal dyspnea which is easily recognized in the typical respiratory distress that comes on suddenly with great severity and presents a clear cut picture. The patient may retire feeling well and after three or four hours' sleep he is suddenly awakened with a feeling of suffocation and is forced to sit up in bed. The duration of the attack is variable from a few minutes to several or more hours. After the attack is relieved he retires to bed and sleeps until morning. Once these attacks begin they usually continue. The class of case that shows this condition is one suffering from arterial and coronary sclerosis. They have high blood pressure for which they have been under treatment for some time prior to the onset of the asthmatic attacks. The heart is always hypertrophied and there is an associated nephropathy. Treatment does not bring about gratifying results, perhaps on account of the profound organic changes complicating or causing the cardiac embarrassment.

In the asthma of renal disease there are albumin and casts in the urine; the heart is hypertrophied, there is high blood pressure. Uremic asthma is in fact a cardiac asthma and does not present any special peculiarities.

Chronic unresolved pneumonia resulting in asthmatic symptoms can be differentiated by a definite history of acute pneumonia, grippe or influenza infection. When the history is vague röntgenoscopy of the chest will aid materially.

The differentiation from tuberculosis depends upon several factors. In the active state there always is an evening rise of temperature. If the process is walled off fever may not be present. Hemoptysis may occur. Signs of cavitation not in close proximity to a bronchus will favor the diagnosis of tuberculosis. The presence of tubercle bacilli is of course pathognomonic. Röntgenoscopy may give important aid.

A patient with syphilis of the lungs giving rise to asthmatic symptoms may give a history of primary or secondary lesions. A sputum persistently negative for tubercle bacilli calls for a Wassermann test. Röntgen ray examination of the lungs will often suggest syphilis.

Foreign bodies or new growths in the larynx, trachea or bronchus, may give rise to a cough and asthmatic symptoms. A laryngoscopic, bronchoscopic and x ray examination will point to the local condition. A positive history of swallowing a foreign body is of help while a negative one does not necessarily exclude foreign body (12).

Compression of the bronchi or trachea by enlarged glands, aneurysm or mediastinal growths give rise to a characteristic wheeze. A high pitched note is heard over the trachea. A brassy cough is characteristic of tracheal pressure. There is a dullness over the bronchi or trachea. In aortic aneurysm the early and common symptom of pain with subsequent expansile pulsation, abnormal dullness and systolic bruit with perhaps inequality of the radial pulses, tracheal tugging and pressure symptoms on the recurrent laryngeal nerve will serve as differential points. Fluoroscopy and röntgenoscopy will show a shadow under the sternum.

Neuhof (13) has described a type of bronchial asthma due to reflexes emanating from a diseased dilated aorta. Rarely, the size of the aorta may be

normal. The symptoms and signs characteristic of primary myocardial insufficiency asthma are lacking, the outstanding physical finding is that of an aortitis. Where the latter is of luetic origin, specific treatment may bring relief of the asthma.

New growths of the lung may simulate asthma. They are secondary to a growth somewhere in the body, rarely primary. Depending upon the location of the tumor the signs will vary. There may be signs of compression of the vessels at the root of the neck and the trachea or bronchi. There is dullness, at times not continuous over the affected area. As it invades the pleura there is effusion.

TREATMENT

The treatment of primary myocardial insufficiency asthma is as a rule satisfactory. It consists mainly of diet, rest and digitalis.

Digitalis is just as efficient in this condition when the heart beat is regular as it is when auricular fibrillation is present. It is important that a standard potent tincture or other reliable preparation of digitalis be used. To get the desired results, digitalis must be given in adequate doses. The maximum therapeutic effect should be obtained without upsetting the patient. It is of interest to note that relief from the distressing asthmatic symptoms is often experienced before an adequate digitalis effect is obtained and before it has effected a material reduction in the pulse rate. If the drug is discontinued and activity resumed at this time, a return of the asthmatic and other symptoms quickly ensues. However, after a normal pulse rate is established and maintained in the early cases, such symptoms as cough, dyspnea and restlessness are entirely eliminated. In cases that come for treatment in the late stage of the disease when chronic bronchitis and emphysema are already established, the cough will still remain though the patient sleeps well. The fatigue will be markedly relieved although a sense of weakness may persist for some time. Treatment directed to the bronchitis will also give relief.

Rest is of extreme importance. Depending upon the degree of myocardial insufficiency present, rest should be absolute or relative. Rest alone at times may replace digitalis in the early cases. Ambulant patients must be given detailed instructions as to what is expected of them. A great deal of attention must be paid to saving the heart from strain. It must be emphasized that the prevention of heart strain depends upon the patient entirely and that without his cooperation, treatment by drugs alone will be of no avail.

The regulation of diet, fluid and salt intake, is similar to that for cardiac diseases in general.

The use of epinephrin hydrochloride is contraindicated. It has been known to cause sudden death in cases of asthma with myocardial insufficiency. It does not cause relief of the asthmatic symptoms secondary to a myocardial insufficiency.

Vigorous catharsis must not be resorted to. Morphine should be restricted to a minimum if not almost entirely eliminated.

Oxygen inhalations properly administered and vigorously pushed proved life saving in the advanced heart failures before an adequate digitalis effect could be obtained.

Where a change of climate has benefited an occasional patient, a definite history of prolonged inactivity could always be elicited and considered accountable for the improvement.

Adams (14) reported a series of fifteen ambulant patients from forty-two to sixty-four years old, suffering with nocturnal paroxysmal asthma, treated with desiccated thyroid gland. Classified clinically, four patients had myocarditis, six aortic disease and five arteriosclerosis. It is of interest to note that three of the four unimproved patients were of the myocardial group, with a pulse rate of 80 before treatment was begun and that they reacted badly to thyroid gland therapy. In connection with this point I may add that some of my patients before coming to me had been treated with pluriglandular extracts because of their asthenia, low blood pressure and the fatigue syndrome, without the slightest relief.

Relapses are inevitable; but they should be anticipated by recognition of the earliest subjective symptoms. To secure the highest degree of myocardial rehabilitation possible, the treatment should be sufficiently prolonged. The patient should be under constant observation and present himself for examination at frequent intervals.

COMMENT

The first signs of failure of the circulation due to myocardial insufficiency are always subjective and are referred to the respiratory system; therefore respiratory distress in response to effort is among the earliest signs of myocardial insufficiency. Primary myocardial insufficiency asthma is easy to recognize in its earliest stages if one will bear this in mind.

Why a certain group of heart failure cases should present typical asthmatic symptoms can not in the present state of our knowledge be satisfactorily explained, except possibly on the hypothesis that these individuals have an asthmatic predisposition. It is known that lung engorgement predisposes to bronchitis. The latter condition can only be looked upon as a contributing factor in the production of the asthmatic symptoms because when the circulation is restored by the administration of digitalis the asthmatic signs clear up. A subsequent attack of bronchitis while the circulation is efficient does not produce asthma.

It is the tendency today to associate asthma with some form of protein sensitization as the etiological factor. Failure to elicit sensitization ends the patient's hope of relief. These insensitive cases are chiefly those past middle life. In a comparatively large number of these cases, although the physical signs of cardiac impairment are not marked or are even absent, the recognition of primary myocardial insufficiency as a factor in the etiology of asthma will help to clear up at least some of these previously incurable cases. Failure to recognize this symptom complex heretofore has been due principally to a tendency on the part of many practitioners to cling to the orthodox idea that circulatory failure sufficient to cause asthma must be associated with the profound organic lesions as met with in cardiac asthma. This symptom complex is being studied by means of instrumental methods with the view of determining their value in checking up the effects of treatment.

CONCLUSIONS

1. Primary myocardial insufficiency asthma complex is an important etiological factor in certain types of asthma in individuals past middle life.

2. An increased pulse rate, regular and persistent, in conjunction with a history of subjective symptoms indicating the earliest stages of myocardial failure together with the age of onset over forty and more usually past middle age, is diagnostic of primary myocardial insufficiency asthma, when other causes of asthma could be excluded.

3. The administration of digitalis in adequate doses serves not only as a diagnostic measure, but is strikingly efficacious in relieving the symptoms.

4. The injection of epinephrin hydrochloride does not relieve the asthma, and is contraindicated.

5. The clinical detection of primary myocardial insufficiency asthma requires no special skill. It is within the reach of the general practitioner if he will give it some consideration and thought.

Radiotherapy Technic

J. D. GIBSON, M.D.,
Denver, Colo.

The subject of radiotherapy is getting to be of great importance and attracting the attention of the medical world as never before, and in the healing art has become a daily necessity. Ten to twenty years ago the literature on the subject of radiotherapy was very meagre and that confusing. It was directed almost entirely to malignancy while today there are many journals devoting much time to chronicling its march of progress.

The technic of radiotherapy is the art of coordinating the four great factors in the production of x rays in a manner to procure the quality and quantity of ray desired in a given case. This art has been perfected and brought nearer to a real science today than ever before. New instruments of diagnostic precision, known as the iontoquantimeter and ionizing chamber, while quite complex in their use, have been of great value in stabilizing all means of measusing the dose of x ray. In fact, the great improvement in measurements of dose and technic generally make the use of the great two hundred and three hundred KV machine possible. By the use of the ionizing chamber there can be mapped out and calibrated data for ordinary use in producing an exact dose through specified filters of one mm. and one and a half mm. copper and also from five to ten mm. of aluminium for exact distances almost through the whole body. Erythema doses in quantity can be delivered for several inches into bodily tissues with great precision. While the use of these ionizing chambers are an imperative necessity for exact doses of the larger machines, they have otherwise helped to conform and stabilize the more common measurements of spark gap and current, which have been in general use for some time and are yet the practical means of measurements for the great majority of our therapeutic work at the present time.

The four supreme factors of importance are: Spark gap—KV; distance; milliamperage (current); time. It is possible that if three of these factors are known the fourth can be readily determined. The problem of doses is illustrated thus:

$$\frac{\text{Ma} \times \text{KV}^2 \text{ or spark gap} \times \text{time}}{\text{Distance}^2}$$

This will give you the dose employed in ma. minutes as:

$$\frac{5 \text{ ma} \times 8^2 \times 6 \text{ min.}}{8^2} \text{ equals 30 mp. min.}$$

If you wish to give—say a 45 m. dose it could be worked out as follows:

$$\frac{6 \times 9^2 \times 6}{8^2} \text{ equals 45 mp. min.}$$

This gives us a full erythema dose.

Remember: A decrease in current increases time 10/3; increased distance increases time 9/4; decrease gap increases time 3/2.

Filters may range from one mm. aluminium to one mm. cu. In current of one hundred KV or less aluminium filters are ordinarily used and in deep work and heavy voltage five to ten mm. may be employed. In general superficial use, while not exceeding five to six ma. of current, three to four mm. aluminium are sufficient and in light superficial work frequently no filter is required, but where the current is light but voltage high and a long time treatment is to be given, a filter is needed. Erythema dose—skin tolerance—is forty-five mp. min.

	equals
Intensive dose—filter	1¼ H 4 Hamp 10 X
Semiintensive dose or Inhibition dose. 2 to 4 alu. filter	½ H to 1 H 3½ Hamp 4 X to 8 X
Fractional or Stimulating dose. Light filter	⅛ H to ½ H 1 X to 4 X 1/10 Hamp to 2 Hamp

Nearly all skin conditions respond better to short wave lengths and as a rule spark gaps five to six inches should be used and when filter is employed use eight to nine inch spark gap. Frequently dose one eighth H to one half H may be given once or twice weekly. Semiintensive dose, one half H to one H may be given biweekly. If filter is to be used the quantity may be increased from one H to two H. Intensive dosage, one H to two H without filters, and when filters are used the dose may be increased to two and three H monthly—not oftener with safety.

Effects of radiation, for convenience, are ordinarily divided into three groups, namely, stimulation inhibition and destructive.

STIMULATION

Many human ills are due to a lack of coordination f cell and nerve magnetic impulses, as well as to hany hypofunctional or hyperfunctional conditions. he blood supply may be at fault either primarily r secondarily. There may be primary, secondary or ptic anemia. Most of these conditions can be enefited through this stimulating effect of radiation. o not understand me to make a claim as a cureall or the x ray. With the variation in dose already inted at, many diseases can be reached by this meth-1. While many diseased conditions can be cured y the x ray there are many of them that can be ired more quickly and economically by other means ian the x ray.

The x ray is going to cause a closer study of the iology and pathology of all disease processes. A eat advantage of radiotherapy is that you can ply it where you need it. It does its work in the finitesimal tissue cells, it can stimulate cell proeration, division, and increase its vigor, vitality and ne, producing an equilibrium in the unbalanced lls. The law of Arndt and Schultz declares that e power that stimulates to destruction can stimue to health. It has been demonstrated for years at the x ray can and does overstimulate to destrucn the cancerous cells in malignant conditions. I ote for ten or more years on x ray stimulation cells to health and vigor.

Schmidt has been able to demonstrate the stimuing effect of radiation on living cells in a most isfactory manner. He was able to demonstrate at normal cells under the effect of stimulating ses took on vital stains rapidly and in an increas- quantity, while in those submitted to a heavier se the amount of stain was inhibited and was more seminated in the cell and the cells that had reved destructive doses of x ray did not take on any in whatever.

Stephan of Germany has successfully stimulated liver and pancreas in diabetes, the kidney in acute enchymatous nephritis, and the stomach in achylia trica.

Much work is being done and the literature is ndant in regarding the use of x ray stimulation hypofunctioning organs, as the ovaries for dysnorrhea, the periosteum for ununited fractures, nulating doses to the liver, pancreas and adrenals. ch is being accomplished in x ray applications to hypophysis as an aid to the production of endoe hormones. The endocrines are attracting much ntion in this line of work at the present time. ne authors assert that through the hormones and nges produced in the endocrine glands many dis- can be reached and relieved more quickly than direct treatment of the offending organ.

ritz Hilpert, of the Erlangen Clinic, states that x ray can cure tuberculosis anywhere in the body. nkel advocates a dose of sixty per cent. HED in tonitis and in tabes mesenterica. He asserts two things are required: stimulation of the acies of the local cells and elevation of the general gocytic powers of the body, both of which can ccomplished by means of the x ray. Many be- that this mode of treatment should be classed vaccines, milk, and split protein products.

My work and assertions in the treatment of tuberculosis by the stimulating and invigorating effects of x ray upon normal and pathological tissue cells are being sustained. My formula of treatment is as follows:

For thin patients:

$$\frac{2 \times 8^2 \times 10}{12^2} \text{ equals } 1/4 \text{ H}$$

to

For heavier patients:

$$\frac{3 \times 8^2 \times 10}{12^2} \text{ equals } 1/3 \text{ H}$$

One of these doses is given three times weekly, treatment alternating from the back to the front of the chest and are given through two mm. of aluminium followed on alternate days with a one pole static stress application.

Eczema requires fractional doses ordinarily and the doses can be repeated once or twice weekly until an effect is noted.

INHIBITION

In this class of cases we will place those requiring amounts of x ray ranging from one half H to the full H or near the full erythema dose. It is to take the place between definite stimulations and complete destructive effects. Many eczemas, lupus, superficial exudates and carbuncles will come in this class. Instead of trying to mention all conditions applicable under this heading, I will mention only a few. Alopecia, ringworm and favus will usually come under this heading with the dose ranging around one H or

$$\frac{3 \times 9^2 \times 9}{8^2} \text{ equals } 35 \text{ mp.}$$

and this dose can be repeated in two to three weeks if needed and the formula can be changed to suit individual machines. Goitre may be classed under this same heading and treated with the same dose biweekly. Occasional cases of goitre do well with fractional doses. In treating goitre in this way you will have some failures and then again some brilliant results.

INTENSIVE DOSAGE

This is usually to be given with filters ranging from four to ten aluminium to one mm. cu. Kroenig places the erythema dose or skin tolerance measured by the ionizing chamber at 170 E and all the massive depth doses are calculated from this surface dose.

Kroenig's comparison of his dose with H is as follows:

Kroenig's 75 E equals, with aluminium filter 3 to 10 mm., 1.5 H.

Kroenig's 150 E equals, with one mm. copper filter, 2.5 H.

As it is more practical I will still use the H as our unit for calculating the massive doses. The author reported a case of uterine fibroid of immense size treated with benefit by means of the x ray, in 1902 before the American Electrotherapeutic Association, and from this little beginning has developed one of the most popular methods of treating these conditions. These tumors usually require a rather heavy dose. Kroenig's ovary and fibroid dose is put down as 33 E and the formula is

$$\frac{33 \text{ E}}{170} \text{ equals } \frac{1}{6}$$

and with this dose he rarely fails to produce successful results as regards tumor and symptoms.

Carcinoma and other malignant conditions have received more attention at the hands of the radiotherapist than any other pathological conditions and the whole world is watching and hoping that a definite and positive cure for this dread malady will be developed by means of this agent.

Kroenig has worked out a dose known as a carcinoma dose and when applied correctly causes the disappearance of the disease very rapidly as far as sight and touch are concerned, and with much tainty this dose is stated at 150 E and the equatio

$$\frac{170\ F}{150} \text{ equals } \frac{5}{6}$$

There is no doubt this is the correct amo of energy to use in these cases and if cannot give this dose at one sitting it should delivered with largest KV possible and in as sh a time as safety will permit with the largest machi at your disposal.

The X Ray as an Aid in the Differential Diagnosis of Abdomina and Chest Conditions*

LOUIS EDEIKEN, M.D.,

Philadelphia, Pa.

In presenting this subject, diseased processes within the chest and abdomen have been selected, in which the predominating symptoms may be referable to one region, but the pathological lesion located in another.

In no other field is the diagnostician's judgment taxed to a greater extent. It is of prime importance that his conclusions be correct, for in the one case immediate surgical intervention may be necessary and in the other, contraindicated. An incorrect decision in either case would result disastrously to the patient. The clinician, therefore, should avail himself of every possible aid to perfect a diagnosis.

The chief lesions in which the clarifying influence of the röntgenologist is of supreme importance are in the differentiation of:

1. Pneumonia from acute appendicitis, especially in children. 2. Empyema from subphrenic abscess. 3. Pleurisy from cholecystitis. 4. Traumatic pneumo or hemopneumothorax from intraabdominal perforation and hemorrhage of traumatic origin. 5. Cardiac and aortic lesions from suspected lesions of the stomach and duodenum. 6. Lower esophageal conditions from gastric lesions. 7. Tumors of liver and spleen from masses in lower lobes of the lungs.

No more striking illustration of the difficulties encountered and the importance of the conclusions can be given than the differentiation between early pneumonia and acute appendicitis, when pain in the lower right quadrant is the most conspicuous symptom. All the symptoms ushering in a pneumonia may be present but are overshadowed by the pain and tenderness in the right iliac fossa. The diagnosis is of increasing difficulty because in the early stages of some of these cases no physical signs of pneumonia may be elicited.

If pneumonia be the causative factor of the pain, and consolidation exists, it is clearly demonstrable on x ray films and often at the fluoroscope. If the pathology has not progressed to consolidation a hazy appearance resembling a cloud of cigarette smoke is seen, indicating an inflammatory process. The contrast between the hazy base and that of the c one is quite decided. If there is no existing p monia, the normal radiability of the lungs is disturbed.

This is considered of such importance on on the pediatric services at the Mt. Sinai Hospital there is a standing order that all children, in w an acute appendicitis is suspected, shall have x ray study of their chests to eliminate the sibility of pneumonia before any surgical inter tion is considered. In hospital procedure, this amination is easily carried out and now, with perfection of the portable x ray apparatus, is al as easily accomplished in the home of the patient

Empyema, one of the most frequent complicat of pneumonia, is the condition most frequently fused with subphrenic abscess, because of the s larity of symptoms and physical signs. The his is quite different. The diagnosis can be readily m at the fluoroscope in conjunction with films. subphrenic abscess the diaphragm is greatly elev and its respiratory excursions are restricted. costophrenic angle is clear and the radiability of lung is normal. There is an increased density the liver area. In empyema, the röntgen pictu a totally different one. The diaphragm is not s the costophrenic angle is obliterated and a fluid is seen. The normal lung radiability is replace a dense shadow in its lower portion. One can r ily see while clinically these conditions can be fusing, röntgenologically there is usually little culty in differentiating them.

The pain due to pleurisy often simulates that to cholecystitis to such an extent that at times confusing. Where pleurisy is the causative fa fluoroscopic examination reveals limitation of excursions of the diaphragm and the pictures close some evidence of pleural adhesions or th ening, if the process be chronic. Where the pa of gallbladder origin, the x ray of this organ be of great value. With the improved technic a better understanding of the obstacles to be c come, the x ray diagnosis of diseases of the bladder has reached a fairly high degree of accu

*Read before the Southeast Branch of the Philadelphia County Medical Society, November 1922.

Calculi are found with more frequency than in the past and in many cases in which we are unable to demonstrate the presence of calculi, the shadow of the gallbladder is shown. It is the consensus of opinion among radiologists that normally the gallbladder casts no shadow and when it is seen on the films it is considered pathological. If the routine pictorial study reveals nothing abnormal in the gallbladder, a bismuth study of the stomach and duodenum may give us some information. Reflex signs such as gastrospasm, six hour retention and hyperperistalsis suggest cholecystitis. Distortion of the duodenal cap without other signs of duodenal ulcer justifies the diagnosis of pericholecystitis with adhesions. No negative gallbladder diagnosis should be made without a combination of these methods.

In discussing trauma, a recent case will serve to illustrate the importance of determining, if possible, whether it be a chest or abdominal injury. A young boy, run over by an automobile, was brought to the hospital in extreme shock, respirations slightly labored and with pain, tenderness and rigidity in the upper abdomen. Injury to the abdominal viscus, probably liver with internal hemorrhage was suspected and operation suggested by the surgeon, but the attending physician could not eliminate the possibility of chest injury and suggested an x ray examination. This was done and it revealed a pneumothorax with partial collapse of the right lung. This of course did not eliminate abdominal injury, but was considered sufficient to give the clinical picture presented by the patient. Surgical intervention was therefore postponed. That these conclusions were correct was shown by the youngster's speedy and uneventful recovery. The röntgen picture of severe chest injury usually shows fractured ribs, the presence of air, sometimes fluid (blood) and air, depression of the diaphragm, collapse of the lung and displacement of the heart toward the unaffected side. In the early stages, injury to abdominal viscera with hemorrhage cannot be shown by x ray examination, although after a few hours a haziness, resulting from the presence of blood, may be noted in both flanks and if the stomach or colon has been injured, a shadow of decreased density resulting from the presence of gas may be visualized in the subphrenic spaces.

Violent trauma to chest or abdomen, may result in a diaphragmatic hernia, a condition rarely seen and less often recognized. According to DaCosta in 50 cases collected by Leichtenstern, only five cases were diagnosed before death. The clinical picture is one of severe shock, dyspnea, cyanosis and pain in the chest and is confused with the typical chest injury described above. Its differentiation is important because the treatment of the two conditions is radically different. No other method except laparotomy is as certain in its diagnosis as an x ray examination, especially if the stomach is the organ involved. The bismuth study will show the stomach to be partially or completely in the pleural cavity.

Now we come to a consideration of a group of chest diseases producing epigastric distress, a rather common complaint and one sometimes difficult to solve. Patients with this symptom as a predominating one are usually referred to the röntgenologist for a gastrointestinal examination. The gastrointestinal tract including the gallbladder is found to be negative, but in the study of the chest at the fluoroscope, a markedly enlarged heart or an aortitis or even a small aneurysm may be found. The clinician is usually aware of its presence but the epigastric distress is so marked that he desires to eliminate a gastric lesion. Röntgenologically, in cardiac disease, the heart shadow is seen to be enlarged in one or all its diameters. In aortitis, the aortic shadow is widened and calcareous plaques may be found imbedded in its walls. In aneurysm, a pulsating mass is seen arising from some portion of the aorta.

Lesions of the lower portion of the esophagus are frequently causes of epigastric discomfort. The most frequent lesions are cardiospasm and organic stricture and these must be differentiated from gastric lesions. The x ray appearance of cardiospasm is as follows: There is more or less complete obstruction to the passage of solid foods. Semisolids and liquids are delayed. The lower border of the stricture is smooth, regular and conical in shape, with a symmetrical termination. The esophagus above the involved area is dilated.

In organic strictures, instead of having smooth, regular margins we find that one of the walls is markedly roughened and irregular and there is an encroachment on the lumen of the esophagus. There may be some dilatation above the stricture, but it is not usually as marked as in cardiospasm. Benign cicatricial strictures give the same röntgenological picture as malignant lesions and must be differentiated by history and other data.

The epigastric distress due to lesions of the stomach, duodenum, gallbladder or appendix is not within the scope of this paper and will not be discussed.

The last differentiation to be considered is between tumors of the liver, kidneys and spleen or elsewhere in the vicinity of the diaphragm, and masses in the lower lobes of the lungs. Very frequently the mass can be shown on the x ray film and fluoroscopic study can determine whether it is abdominal or thoracic, but it is very often difficult to say with which viscus it is connected. In these cases, as well as any condition around the diaphragm where the ordinary methods of diagnosis have failed, a pneumoperitoneum study may be of great value. It will readily show whether the lesion is supra or infra diaphragmatic and show changes in contour and size of the solid viscera, i. e., kidneys, spleen, liver and also the gallbladder. In this method air oxygen or carbon dioxide or a combination of the two is injected into the peritoneal cavity. The puncture is done in the same manner and under the same aseptic precautions as the ordinary abdominal paracentesis. Care must be taken that gas is not introduced too rapidly or too forcibly. In women it is sometimes advisable to use the transuterine route, if there are no contraindications. Pneumoperitoneum has a distinct value but it is not recommended as a routine procedure. We must remember also that certain conditions, such as cardiovascular diseases, diffuse infection and extremes in ages, contraindicate its use.

This in brief covers the important confusing abdominal and thoracic lesions, as seen by the röntgenologist. I have shown you the methods employed, their value and limitations, in this particular field.

1923 Spruce Street.

Symptomatology and Diagnosis of Polycystic Kidney*

JOHN H. MORRISEY, M.D.,
and FREDERICK W. SMITH, M. D.,
New York,

Assistant Attending Surgeons, Brady Foundation New York Hospital, New York City and St. Bartholomew's Hospitals; Consulting Surgeons, New Jersey State Hospital, Trenton

Cystic disease of the kidney, including the two types, solitary or single cyst and multiple cysts, is a condition of comparative rarity and of sufficient clinical importance to warrant a report of all cases. Its relative infrequency, its etiology, and its symptomatology are three facts which form the major portion of the idea which most of us have readily at hand in reference to the condition. Studies as to its unilateral or bilateral nature seem to have crystallized thoroughly into the conclusion that it is always bilateral. Congenital and adult types are also conceded, which present different types of symptoms. Its familial occurrence has been strengthened by numerous observers, most recently by a careful study on the part of Crawford. The familial incidence, it was determined, had extended throughout four generations. The report is most interesting. Over fifteen cases were noted in the four generations, and in one case, seven children all had polycystic kidneys. One is living at the age of seventy-six years, three of the children died in uremia, the remaining four married and the condition was noted in their offspring.

Zeit, of Chicago, reported the occurrence of heredity in three generations, as follows: A forty year old mother and a one year old baby, both with bilateral polycystic kidney disease; the patient's father died from polycystic disease; all her children (four) are now suffering from kidney disease, presumably polycystic.

Barnett a few years ago, from an extensive correspondence with the surgeons, anatomists, pathologists, and the clinics and institutions where surgery is practised and taught in North America, collected 251 cases. This demonstrates the infrequency of occurrence. The diagnosis is seldom made previous to operations or autopsy. In two of our cases an exact clinical and pathological diagnosis was established by pyelography.

Occlusion of the urinary tubules seems to be the pathogenesis of the cyst formation. It is hardly necessary to mention the various theories which have at times held sway or have been advanced. The acceptance of the defective development of the urogenital organs as the causative factor, seems to be the consensus of opinion. It may be stated briefly that the kidney as a whole is formed of two embryonic structures, the cortex and greater part of the medulla arising from the nephrogenic tissue of the Wolffian body, while the ureter, pelvis, and a portion of the medulla, containing the collecting tubules, are a separate formation from the Wolffian duct. Normally these two parts unite, and the connection becomes established between the former (renal) portion, containing the glomeruli, convoluted tubules and Henle's loops, and the latter (pelvic) portion, containing the collecting tubules. Thus the urinary channels become continuous from glomeruli to calyces and pelvis. The malformation theory is based on the assumption that there is a failure, more or less general, on the part of these two portions to unite, by some atresia, lack of fusion or misalignment, and an obstruction results affecting the tubules of the medullary portion and causing cystic dilatation of the tubular system above the collecting tubules.

The extent of the entire process depends on the relative number of the tubules which do not join. If this is extensive, and the majority of them do not connect, there is no kidney tissue left to eliminate urine—the cystic formation is rapid and death soon supervenes. Similarly if a minor part of kidney tissue only is affected, there is frequently sufficient to carry on the work of elimination, and the patient may live for many years.

Stress is laid by all writers on the prevailing symptoms of kidney insufficiency as associated with this condition. This would hardly seem to be entirely true. Excepting the congenital type the period of active symptomatology may be delayed until well past middle life, the fourth decade, as has been generally observed, is usually a significant time.

Dull pain in the back and loins, persistent headache, frequency of urination, and occasionally hematuria are symptoms which may be noted. Other symptoms are tumor, ptosis, polyuria, toxemia, uremia, backache and abdominal pain. The weight is a menace to the patient. Frequently the urine shows only evidence of chronic interstitial nephritis and unless the cysts communicate with the pelvis of the kidney and are infected, there may be no special indication of this condition. Intermittent hematuria was the main symptom in two of my cases. It was of eleven years' duration in one, painless in type, although at times spasms of ureteral colic were observed, probably due to ureteral clots. This would, therefore, include the possibility of a polycystic kidney in the differential diagnosis of the cause of the hematuria and forms a further reason for the utilization of pyelography and the establishment of the final diagnosis. The practical importance of recognizing this condition is readily apparent, as errors in diagnosis have resulted in the removal of a polycystic kidney.

Careful urological investigation is clearly essential, and in cases presenting a discrepancy of function, delayed phthalein appearance, time, etc., cystic kidney must always be suspected. This is especially true if a kidney tumor is palpable. Chemical examination of the blood may reveal a decrease in the output of the nonprotein content but this is not invariably the case.

*Read before the Genitourinary Section at the New York Academy of Medicine, May 15, 1923

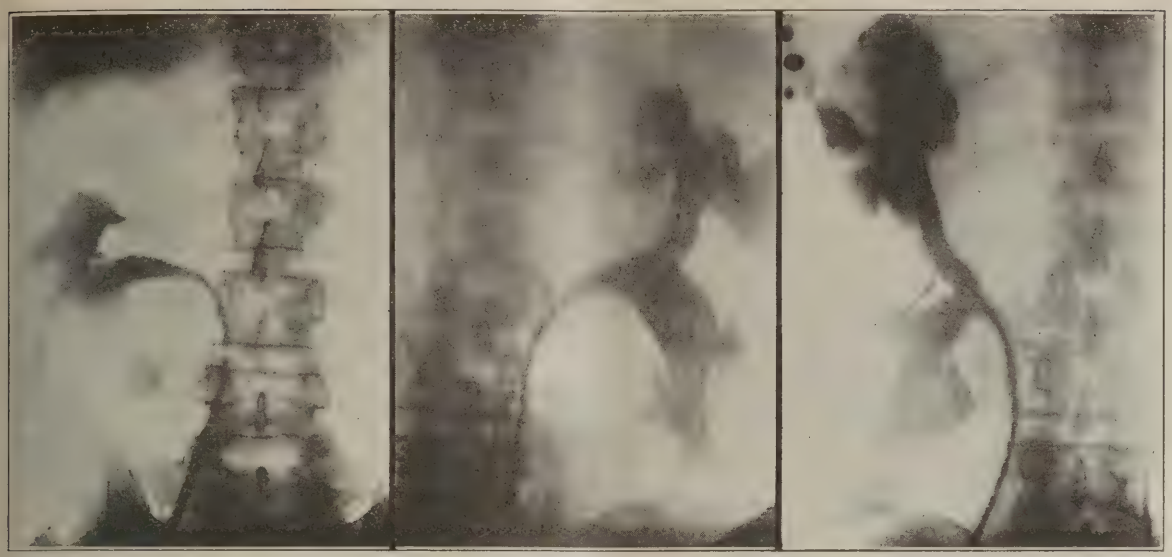

Fig. 1. Fig. 2. Fig. 3.

Fig. 1.—Case I. Note the dislocation of the ureter as it is pushed inward and upward to wind around the tumor; the indefinite character of e calyces and the lack of configuration in the lower portion of the pelvis.

Fig. 2.—Case II. Pyelogram of a kidney showing characteristic configuration.

Fig. 3.—Pyelogram of a tremendous kidney, filling almost the entire abdominal cavity. Only symptom, hematuria for eight years. As can noted the upper margin of the kidney goes to the level of the tenth rib, and descends well below the crest of the ilium.

Pyelography gives a characteristic picture which quite conclusive—usually the kidney contains sev- al times the normal amount of fluid and injection painless. The characteristic symptoms on disten- on of the pelvis are not obtained. There is a finite irregularity of outline which must not, how- er, be confused with tumor. The irregularity is ore or less circular in outline, the size depending the cysts with the socalled cupping appearance d broadening of the pelvis and differing from the ling defects, with indefinite outlines, and bizarre rms, noticed in hyperne- roma.

In polycystic kidney we fre- ently find an obliteration or ortening of the calyces or egular retraction of the lyces due to encroachment the pelvis of cortical cysts. largement of the pelvis and ten change in the axis, gives irregular, oblong or oval ntour resembling pyonephro- , but without pyuria, and a culiar rounded or cylindrical tline, and often a change in e relative position of the pel- s. In hypernephroma we y have complete obliterа- n of the pelvis or narrow eaks and irregular outlines d usually more complete re- ction of the calyces. If a st ruptures into the pelvis of e kidney the opaque medium ich fills it gives a rounded tline which contracts with cysts which encroach on e pelvis.

The recognition of the part yed by faulty development in other portions of the urological tract and their relative frequency leads me to report three cases of polycystic kidney—two of which occurred in my own practice within a few days of each other, and the other about the same time in the Urological Service at New York Hospital.

Case I.—Male, fifty years old, married, no children, mother died of kidney disease. Perinephritic abscess on left side while living in Los Angeles in 1915. It was opened and drained and examination revealed a polycystic kidney. Some sixty cysts were punctured and drained. Two years later a floating or ptosed kidney was found on the opposite side. The chief subjective symptom was backache and pain in the lower quadrant on the right side. The operation had apparently relieved the discomfort on the left side. The urine showed evidence of chronic interstitial nephritis. Both kidneys were palpably enlarged. As a history of polycystic kidney on the left side was obtained, a pyelogram of the right side only was made. The separated urine specimens were obtained and found to be about equal in quantity and contents and comparable to the specimen obtained from the bladder. The phthalein output was four per cent. on the right and five per cent. on the left side in twenty minutes.

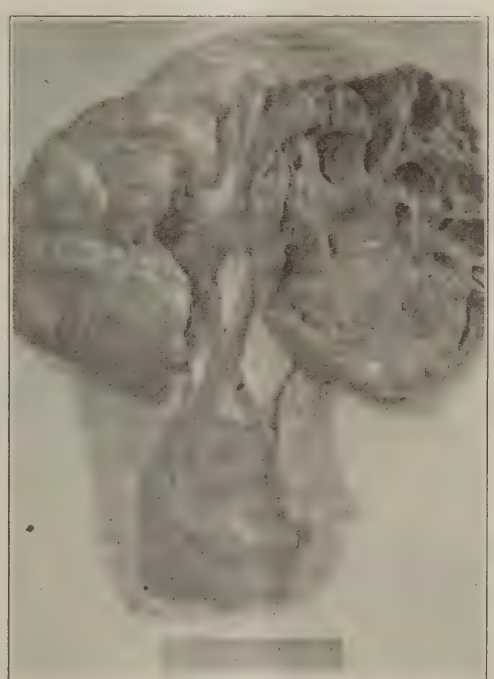

Fig. 4.—Pyelogram of patient, aged twenty-three. Only symptom was rightsided tumor and an occasional pain in the right side, discovered in the course of a routine urological examination. Typical pyelogram can be noted.

Forty c. c. of twenty per cent. sodium iodide solution was injected into the right pelvis without the least dis-

comfort. This was drained off afterwards with apparently little reaction.

Case II.—Male, forty-three years old, married, no children, no hereditary history relevant to his condition. Intermittent hematuria for varying periods and at varying intervals for twelve years.

Fig. 5.—Photograph of a waxed model, made by an artist, of kidneys removed from the patient dying at the age of forty-seven. Relative size can be determined by attached scale. Each kidney was the size of a large watermelon.

During this time three examinations by the Life Extension Institute and two by urologists of prominence were all negative. Present hematuria began seven days before examination with frequency and urgency day and night. Residual urine fifty c. c. Cystoscopy revealed moderate lateral prostatic intrusion and slight trabeculation. The orifices appeared normal and from the left blood was ejected. Catheters were passed easily to the kidney pelves and the urine collected for ten minutes. The specimen from the left side was mostly blood and from the right, urine of low gravity and urea content with a trace of albumin, and no casts or blood. The phthalein appearance time was twenty-five minutes on the left and twenty-six minutes on the right side. Plates and smears were negative for bacteria. The left kidney pelvis was injected with thirty-six c. c. of twenty per cent. sodium iodide solution without discomfort, and pyelograms were made. The opaque medium was drained off and as the patient had no reaction a similar procedure was carried out on the other side one week later.

Case III.—Female, forty-three years old, single. No special prior illnesses relevant to the condition reported. Mother died of kidney disease, the nature of which was not reported.

Present illness began over six years ago when the patient became cognizant of a mass in each flank, which, by pressure, caused physical interference with the functions of the gastrointestinal tract. These symptoms progressively increased in severity until, while in France in 1919, she had persistent vomiting for three days and a laparotomy was decided upon and done, and bilateral polycystic kidneys were found. The operation was exploratory and only for diagnosis. On January 14, 1922, she was admitted to New York Hospital, complaining of abdominal pain—the first acute pain—and intermittent hematuria. The uranalysis showed a low specific gravity, traces of albumin, a few hyaline casts, and a few white and red blood cells. She left the hospital, improved, after a few days, and was readmitted on December 14, 1922. The urinary findings were about the same but showed evidence of uremia. The phthalein output was six per cent in the first and twenty-five per cent. in the second hour. The blood urea increased in ten months from 61.16 to 84.64 and the creatinine content from 4.4 to 13.32 milligrams in 100 c. c. of blood.

Owing to retention and the increasing uremic symptoms an operation seemed imperative and was done on the left side under gas and local anesthesia, December 18, 1922. Numerous cysts were aspirated and 2,200 c. c. of fluid removed. In some of the pockets the fluid was thin, clear or brownish and in others blood tinged. As the needle was withdrawn

Fig. 6.—Pyelogram of patient in Fig. 5, made after kidneys had been removed. The cystic character of the kidney tumor is quite obvious and the configuration closely resembles the accompanying illustrations.

the wounds continued to ooze so the cysts were punctured—the socalled Rovsing operation. The patient died five days later from uremia. No pyelography was done as the diagnosis was made by operation. I present herewith a picture of the autopsy specimen and postmortem pyelograms.

TREATMENT

This is essentially palliative and must be along conservative lines. One must guard against the enthusiasm of the surgeon in operating for unilateral bleeding, where a cystic kidney is present, and probably bilateral. Frequently until the cyst formation is extensive, the kidney may be considerably enlarged and yet show no definite external indication of obvious cystic kidney. In cases where the symptoms are sudden in appearance and apparently are progressing rapidly, all out of proportion to the development of the condition, the Rovsing operation—namely that of puncturing the cysts, may be performed. The presence of the increasing cystic tissue sometimes may squeeze the remaining healthy kidney tissue and gradually interfere with its function. It is in this type of case that the Rovsing operation is most likely to be beneficial.

One of my patients has been relatively free from symptoms following this operation performed eight years ago.

CONCLUSIONS

1. With the aid of pyelography, particularly in the past two years, a relatively new field has been opened up in the association of clinical symptomatology with pathological anomalies of the genitourinary tract. The condition is universally commanding attention and whereas two years ago isolated cases of double ureter, bifid pelvis, and similar conditions were reported singly and considered unusual, these are now being reported in groups and noted frequently. It is not unlikely that polycystic disease of the kidney may fall largely within the same class. There is no reason to suspect the occurrence of fewer cases of misalignment and faulty development which contribute to polycystic disease of the kidney, than of faulty development, which gives rise to bifid pelvis and double ureters. Attention is directed, therefore, to this fact and the value of pyelograms in the diagnosis.

2. The influence of heredity has been established beyond question of doubt and this factor should always be considered, once the diagnosis has been arrived at. From a prophylactic viewpoint in families where the condition has already been recognized in one, it should be of value in the care of the others.

3. Simple operative methods—puncture of cysts—are often of palliative value. Nephrectomy is indicated only when the function is nil.

4. The obscurity which still surrounds the condition warrants a careful study and report of all cases occurring in individual practices and hospital services, as it is only by a comparison of cases that the real incidence can be proven and progress made in the therapeutic and operative procedures, which may be beneficial.

Pulmonary Abscess Following Aspiration of a Tooth Cured by Artificial Pneumothorax

RAYMOND J. SISSON, M.D.,
Syracuse, N. Y.

A careful search of the literature fails to reveal a case report of an instance similar to that presented in this paper.

CASE REPORT

CASE.—The patient, F. A., a man thirty-nine years of age, entered the hospital on June 20, 1922, complaining of cough and expectoration of ten days' duration, night sweats for two weeks and blood streaked sputum once on the morning of admission. Two weeks prior to admission extraction of a tooth was attempted by a dentist using nitrous oxide oxygen anesthesia, given by a nurse. The dentist asserted that the pharynx was packed in the usual manner and that extraction was uneventful, although the patient's wife stated that he was under the anesthesia for more than one hour. Directly after the extraction, pain was noted in the right mandible, which continued for one week. Another dentist was consulted who treated the right mandible for four days. On entrance the patient's temperature was 100.4°, pulse 84, and respiration 22.

The patient was a middleaged man, good color, bilateral facial flush; did not present the picture of being extremely ill. Nutrition was good and there was no evidence of recent loss in weight. The skin was moist—no unusual pigmentation, no rash or previous operative scars. The conjunctiva was somewhat infected, sclera clear; no exophthalmos, nystagmus, extrinsic ocular movements and convergence good, pupils equal, reacted to light and accommodation, consensual reflex present. Media clear, vessels normal, disc clearly defined, cupping normal, no hemorrhages, no deafness, discharge or tophi. Slight septal deviation to right—some slight discharge. Sinuses not tender, transillumination good. There was anesthesia over distribution of right mandibular nerve. Lips and mucous membranes of good color. Several devitalized teeth were present with caries and pyorrhea. A discharging sinus was present in right mandible. The tongue was coated, tonsils were of moderate size, pharynx injected. There was some cervical adenitis on the right side. The thyroid was not enlarged. The chest was that of a well developed male, symmetrical, no evidence of restricted motion, expansion good. Vocal and tactile fremitus normal. No impairment to percussion, Krönig's wide and equal. Breath sounds vesicular and, except inferior to right scapula, nothing abnormal was heard. Inferior to right scapula, there were heard, after expiratory cough, a series of crepitant râles at the end of inspiration. The apex was in the fifth interspace, twelve cm. to left. Left border of heart thirteen cm. to left in fifth interspace. To the right, two cm. in the third interspace. Sounds clear, regular, no accen-

tuations or murmurs. The pulse was 88, regular, average size and tension. The vessel walls were not thickened. Blood pressure, 130 systolic, over 80 diastolic; weight 144 pounds, height 5 feet, 7¼ inches. The white blood cell count was 14,100.

On the second day of admission, there was a definite area of impairment from the right midscapular region almost to base. The breath sounds were diminished over this area. Numerous sonorous râles with an occasional crepitant râle were heard over this area. There were occasional distant sibilant râles over the left chest.

Stereoscopic examination of the chest on June 22nd showed slight hypertrophy of the heart to the left. In the region of the fourth interspace and eighth spine on the right side, there was considerable increase in interpulmonary opacity suggesting an ill defined consolidation. A small spot of calcification at the peripheral end of this area rather ill defined suggested a tooth or tooth fragment.

There was a gradual fall in temperature and pulse rate for nine days. The patient's cough was much less distressing. Physical signs in the chest were unchanged.

On the ninth day the temperature suddenly rose to 103.2°. There was moderate cough with sudden increase of expectoration. A total of 200 c. c. thick, foul smelling, gray green sputum was raised in two hours. White blood cell count 16,000. Expectoration then became profuse, the odor foul. Postural drainage was started. No elastic tissue found in repeated examinations. The sputum was of the characteristic three layer type. A daily temperature of the septic type began on the ninth day after admission.

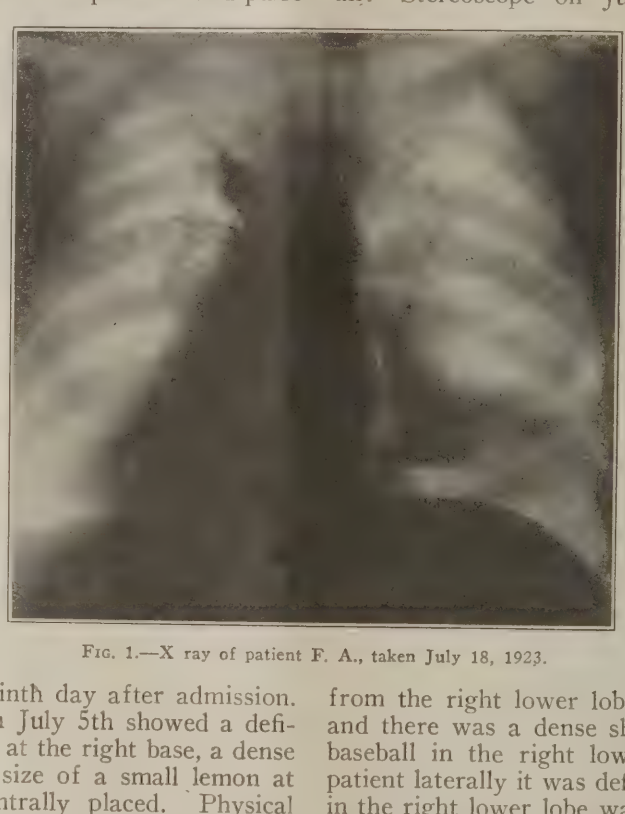

Fig. 1.—X ray of patient F. A., taken July 18, 1923.

Stereoscopic plates taken July 5th showed a definite increase in the process at the right base, a dense shadow being present the size of a small lemon at the right base, rather centrally placed. Physical examination showed restricted motion of the right base, moderate impairment in right axilla, none anteriorly. There was impairment in right interscapular region increasing to practically flatness at base opposite ninth and tenth dorsal spines.

Artificial pneumothorax (air) was induced the twenty-second day of admission, using 300 c. c. of air. Stereoscopic examination of the chest showed upper portion of the right lung partially collapsed due to pressure of therapeutic pneumothorax and in the lower lobe there was a definite increase in density with rather ill defined edges which seemed rather central. The artificial pneumothorax did not extend beyond this point, being prevented by adhesions, apparently. At the upper edge of this density was a small irregular shadow.

Pneumothorax with 650 c. c. of air was induced the twenty-fourth day after admission. The temperature began to drop after the first injection and continued to drop. The sputum was somewhat increased, the cough lessened.

Pneumothorax was again employed on July 18th the twenty-eighth day of admission, using 340 c. c. of air. The stereoscope showed therapeutic pneumothorax more marked, the upper part of the lung being more collapsed. The abscess cavity was smaller and a calcified shadow of higher density than the rib suggested the possibility of a tooth root. Adhesions were still present in the lower portion of the lung, preventing greater collapse. There was a moderate collection of air above the diaphragm. The temperature became normal for two days, then rose again to 102° daily with some remissions. The left border of the heart was 15.5 cm. to the left. Pneumothorax was again induced the thirtieth day of admission of 400 c. c. of air. Stereoscope on July 25th showed pneumothorax increased still more in the upper portion of the right chest. The abscess cavity appeared to have filled up again, the shadow in the lower was much denser and more extensive. The adhesions were still pronounced. The foreign body was still present.

Fluoroscopic examination on July 27th showed some dislocation of the heart to the left. Considerable pneumothorax was present, the upper and middle lobes on the right side considerably collapsed. Some air was present above the diaphragmatic dome. Between this and right lower lobe adhesions were evident, extending from the right lower lobe to the lateral chest wall and there was a dense shadow about the size of a baseball in the right lower lobe. On turning the patient laterally it was definite that the consolidation in the right lower lobe was posterior in a fan shape with the greatest diameter toward the periphery.

On July 29th, the thirty-ninth day after admission, the patient coughed up a tooth fragment with blood streaked sputum. The temperature dropped to normal and so remained. There was no cough. The patient was comfortable. Stereoscope showed abscess cavity a little less full, otherwise no change. Pneumothorax was a little less marked. The temperature continued normal and on August 2nd, the forty-third day after admission and the fifty-third after extraction, the patient, while conversing with a dentist, coughed, noting something in his mouth. It was a tooth. Stereoscope taken August 3rd showed the pneumothorax about the same, the abscess cavity almost completely collapsed. No foreign body was visualized.

The patient continued to improve. The physical signs in the chest remained unchanged up to discharge seven days after expulsion of the tooth, except that the pneumothorax was being gradually absorbed. The patient spent six weeks in Arizona, returning for an examination October 31, 1922. His weight was 166 pounds. He was absolutely well and stated that he never coughed after expulsion of the tooth.

Stereoscope taken October 31, 1922, showed moderate cardiac hypertrophy. General lung radiation clear. The diaphragm on the right side showed some restriction of movement apparently being attached to the phrenocostal angle by adhesions. The right lower lobe was about two or three fingers' breadth above the diaphragmatic dome, and showed some localized haziness in the general region where the former abscess was. This was not marked and in all probability was the shadow of scar tissue.

COMMENT

Postural drainage seemed to be of some benefit but it was not marked in this case. Bronchoscopy was considered but deemed inadvisable on account of the peculiar location of the foreign body. Improvement was noted directly after pneumothorax treatment was started, culminating finally in expulsion of the foreign body. As this was followed by immediate improvement subjectively and objectively it seems fair to assume that the pneumothorax was the active agent in effecting the cure.

915 Willis Avenue.

Impotence in the Male: Its Practical and Scientific Treatment*

MAX HUHNER, M.D.,
New York

If physicians would only understand that the organs making up the sexual apparatus respond physiologically and pathologically just like other organs in the body, the treatment of impotence would not be the mysterious or foolish method so often prescribed. What would a throat specialist advise a patient who was suffering from hoarseness due to a highly congested condition of the vocal cords? What would a surgeon advise a patient who was unable to move his elbow as a result of a highly inflamed condition of that joint? Would not both these specialists, in entirely different fields, advise immediate rest of the respective organs to get rid of the acute congestion, before making any attempt to induce the organ to perform its function? This is plain common sense. Would we not laugh at a throat specialist who would advise such a hoarse patient to talk as much as possible, on the theory that exercise of the muscles involved would tend to strengthen them, and thus restore the voice? This again is common sense.

But when we come to the treatment of impotence, we find just such a foolish method of treatment advised by many practitioners. For some reason the opinion seems to have become prevalent that the muscles, bloodvessels, nerve centres, etc., involved in the functions of the sexual apparatus, work in some mysterious manner, entirely different from those in other parts of the body.

The poor patient who has become impotent as a result of extreme congestion of the prostate and prostatic urethra, has one aphrodisiac after another thrown into his system, local stimulating treatment applied, until finally the entire sexual apparatus becomes completely exhausted, and refuses to respond to further stimulation, and the patient is left totally impotent.

Considering the entire subject of impotence from a rational point of view, the overstimulation of tired exhausted muscles and nerve centres is contrary to laws of physiology and pathology, yet this is the method employed by many practitioners, because, as stated above, the belief is prevalent that the muscles, nerve centres, and circulation of the sexual organs are for some mysterious reason different from muscles, nerve centres and circulation in every other part of the body.

Let us now consider very briefly the course of events in normal physiological erection. During the preliminary sexual excitement the parts become hyperemic. At the close of ejaculation, detumescence occurs, that is, the blood gradually leaves the parts, until finally they are in their natural state. Should the normal mechanism of coitus be interfered with by withdrawal, or similar unphysiological practices, the turgescence does not leave the parts as in normal coitus, but persists for some time. A single act of withdrawal probably does no or very little harm, but if the practice is indulged in for months or years, there occurs, as a result of the frequent long continued congestions, a state of chronic congestion of the prostate and prostatic urethra, just as is the case in diseases of the nose or throat or any other organ of the body. The same pathological condition of chronic congestion may be brought about in individuals during the sexual excitement of prolonged spooning incident to long engagements. In this later state of affairs it frequently happens that the young man calls on his sweetheart night after night and indulges in intense sexual play, during which time the entire sexual apparatus becomes markedly congested preparatory to coitus which does not take place, and the parts are left in a condition of congestion. Here again one offense probably does little harm, only the long practised or frequently repeated acts, especially where the engagement has been prolonged to several years, will end in the same condition of chronic congestion. Should such a patient find himself suffering from premature or rapid ejaculation at his first marital attempts, a certain group of sexologists would

*Read at a meeting of the New York Physicians' Association, October 24, 1923.

immediately put it down as a case of impotence due to continence, and would descant upon the evil effects of continence. As a matter of fact, such a person has not been really continent, but, on the contrary, has been *overusing* his sexual apparatus in the most shamefaced and unphysiological manner. Any observer can satisfy himself of this final outcome by feeling the congested prostate or seeing the congested posterior urethra and swollen verumontanum through the urethroscope in such an individual.

I have repeatedly emphasized one point in performing urethroscopy in such cases. The beginner may expect to see gross pathological changes or alterations in the posterior urethra. This, however, is not generally the case. It cannot be too strongly emphasized that most gross pathological conditions in the posterior urethra, such as tumors for instance, may not cause any symptoms, and certainly not impotence; but that a congestion of the parts, which might easily be overlooked by the beginner, or thought of little etiological importance, is often the real cause of impotence.

In bad cases, and indeed in most cases of long standing, the congestion is probably not limited to the posterior urethra and prostate, but even the reflex centres in the spinal cord no doubt become hyperemic and respond more quickly to reflex excitation.

What is the clinical result of all these congestions? Exactly like congestions in any other portion of the body. A congested nose will sneeze at the slightest current of air, a congested eye will blink at the slightest amount of light, and a congested larynx will cough at the slightest particle of dust, or at the slightest use of the voice. While in normal coitus, it takes a certain amount of friction before orgasm and ejaculation are reached, in the congested condition of the parts the reflex centres are so irritable, that the slightest friction of the penis is sufficient to cause orgasm and ejaculation. In extreme cases, ejaculation takes place even before the penis has entered the vagina (premature ejaculation) while in others immediately or shortly after entrance (rapid ejaculation).

There is still another very important point in this connection to which I desire to call attention. The desire for sexual intercourse depends to a large extent upon the condition of distention of the seminal vesicles. This has been definitely demonstrated in frogs, in which all desire for coitus disappears when the contents of the vesicles are squeezed out, but if they are now distended by the injection of plain water, then desire returns immediately.

Now, even in normal coitus the seminal vesicles are not completely emptied, and in abnormal coitus, as in withdrawal, they remain much less depleted. In those cases of prolonged spooning without coitus, just described, they will generally be found greatly distended. Thus we will have in these cases of abnormal coitus, a condition in which the vesicles become distended much sooner than after normal coitus, the desire for coitus returns much quicker, coitus is indulged in more often, thus tending more and more to exhaust the already overtired sexual apparatus.

One might imagine, from a consideration of the physiology and pathology just described, that the continent man ought to be tortured by very frequent desire for coitus, as his seminal vesicles would always be in a condition of extreme distention. Here again, I am happy to be able to emphasize that the sexual glands, nerve centres, etc., functionate just like these structures anywhere else in the body. The amount of saliva or gastric juice secreted is increased, not only by the actual entrance of food into body, but even by the sight or smell of food. And so it is with glands everywhere, their amount of secretion depends upon the amount of reflex stimulation, and so it is with the sexual apparatus. In the man who is physiologically continent, the amount of semen produced is comparatively small, it takes a long time to distend the seminal vesicles, and then nature takes care of this by an occasional nocturnal pollution, which is physiological once every ten days or two weeks. But the man who indulges in very much spooning, or keeps his sexual apparatus always in a state of excitement, is not truly continent though he refrains from coitus. In him, there is a large amount of semen secreted, and he really does have increased and repeated sexual desire, and finds it more difficult to restrain himself than his truly continent brother. In him, also, nature tries to come to his rescue by frequent pollutions, which serve to keep his vesicles more or less empty, and is a sign, not that he needs coitus, as many young boys believe, but that he should refrain from unphysiological sexual excitements. Treatment, as described in some of my previous publications (1, 2, 4) will quickly put an end to such pollutions.

If, in spite of repeated warnings in the way of rapid and premature ejaculations, the patient continues the abuse of his sexual apparatus, by such practices as withdrawal, etc., we have again the same result as in other parts of the body. The centres, which have at first merely become overirritated, finally become exhausted and refuse to functionate at all, and we get, as a final stage, the clinical picture of complete impotence, in which neither erection nor ejaculation takes place, although the desire may still be present. The exhaustion of the centres, is not entirely brought about by the frequent demands made upon them by coitus, spooning or other sexual excitements, but is largely due to the reflex stimuli arising from an ever present congested prostate and prostatic urethra, as well as distended seminal vesicles, which are continuously bombarding the centres with reflex stimuli. Physiologically, the centres only receive peripheral reflex stimuli during the local congestion incident to coitus, but, when the parts are always in a state of chronic congestion as before described, the reflex stimuli received by the spinal centres are so numerous that exhaustion must take place.

The same final result of complete impotence I have frequently seen hastened by misdirected advice and treatment. Many such patients are advised by their physicians that their weak erections and rapid ejaculations are purely psychic and imaginary and that they should go on trying coitus, making up their minds that they can have erections, somewhat *á la Coué*, and they will certainly be all right. Other physicians, recognizing that treatment is necessary, start at once with stimulating treatment, by socalled aphrodisiacs, electricity, sounds, etc., at the same time advising the patient to try his powers. The result in

both cases is, and must be the same, just as similar treatment applied to any other inflamed organ in the body must result in failure. We must recognize that nature is trying her best to cure the patient by sexual rest. It does not want the patient to indulge in coitus, and therefore takes away his ability to do so. If a patient under certain pathological conditions ought not to partake of food, nature will take away his appetite, and if, in spite of such warning, the patient does put food into his stomach, nature will make him vomit or give him such distress that he will not be inclined to try the experiment again.

What then is the rational as well as scientific treatment for impotence? The treatment is the same as that applied to any other organ similarly affected. The first essential is absolute sexual rest, no coitus, and certainly no sexual excitements of any kind. Bromides should be given internally to allay as much as possible sexual desire and passion. The patient must be told at the very start what the object and result of the administration of bromides is, otherwise he might think he is getting worse, when he finds his desire diminishing. He must be told that this is exactly what we want. I tell my patients that if I could put the entire sexual apparatus, centres and all, in a plaster cast, just as we insure rest to an inflamed joint, I would gladly do so. There is no danger of a permanent loss of sexual desire from the temporary use of bromides. Epileptics often take bromides for long periods of time, and they do not suffer from impotence from this cause.

The local treatment consists in prostatic massage, and the instillation of weak silver nitrate solutions into the prostatic urethra. As regards prostatic massage, please remember that poking or squeezing the organ per rectum is no more massage of the prostate than giving a man a punch in the stomach is massage of the stomach. Massage is massage whether applied to a joint, an abdominal viscus or the prostate. It is *not* the object to squeeze out every bit of secretion from the prostate. This would be *expression* and not *massage*. Massage must be gentle, especially gentle in these cases because the prostate is congested and hyperesthetic. It is impossible to describe the feel and method of manipulation, but the criterion should be the patient's sensation. Any amount of pain should be a warning either to be more gentle or discontinue altogether.

The use of instillations of silver nitrate into the prostatic urethra is to remove the congestion just as the laryngologist often swabs the vocal cords with the same drug. We do not desire any antiseptic effect of the drug, but merely its astringent and tonic action. For this reason the solution employed must be very mild, starting with a one in 3,000 solution and gradually increasing it at each treatment until a one in 500 is reached. Many practitioners employ a much too strong solution, and hence cannot get results. Pain or bleeding following the instillation is absolutely unwarranted, and does positive harm. The instillation is done with the Bangs's sound syringe.

Many years ago, while I was perfecting this method of treatment for impotence, I subjected the patient to another posterior urethroscopy after a time to make sure that all the local congestion had been removed. Many years of experience have shown me that this is not necessary, and that, when the prostate feels normal to the touch, and the urethra is no longer hypersensitive to the passage of the instrument and the instillation, all congestion has been removed. When the local congestions have been removed, the bromides are discontinued, all restrictions as to diet are removed. We now start the stimulating and developing treatment. For this purpose I employ the sinusoidal faradic current. The current is mild at the commencement, but is gradually increased until it is as strong as the patient can bear. Painful currents must be avoided. Patients are sometimes under the impression, that the stronger the current the better the result, and this will induce them to bear currents of great strength without a murmur. They must be disabused of this notion. The current should be of only moderate rapidity.

With these factors in mind, I employ the method as follows: Any form of rectal electrode is introduced into the rectum, and connected with either pole, and the other cord is connected with an ordinary medium size sound placed in the urethra and bladder. A special prostatic electrode is not necessary. The current is allowed to pass for about ten minutes. I then remove the urethral sound, leaving the rectal electrode in situ. I now apply an ordinary wet sponge electrode to the perineum permitting the current to pass for about five minutes. Then I remove the rectal electrode, and apply two ordinary sponge electrodes to either side of the penis, near the glans, and pass the current for another five minutes.

The rationale of these various applications is as follows: In the first instance, the prostate and prostatic urethra lie between the rectal electrode and the urethral sound, and are naturally stimulated. The second procedure is to raise the tone of the muscles of erection. The last procedure is to improve the sensibility in the skin of the penis, which in some cases is diminished.

The limitations of space permit the discussion of only the most common and important form of impotence. I have therefore omitted the organic and psychic forms, the treatment of which obviously depending upon the underlying cause. These have been discussed in previous publications (1, 2, 3).

In conclusion, I wish to say a few words as to the use of glandular extracts in impotence. I have tried most of them, but thus far the results have been unsatisfactory. I have, however, not lost my faith in this field of endeavor, and believe that the day will come when, in selected cases, results will be achieved. The occasionally remarkable results from testicle implantation, and the excellent results reported by competent observers from the Steinach operation, both point to the probability of approach along the lines of endocrine therapy. Moreover, the decided results which most of us have perceived from the use of extracts of the female sexual glands, bids us hope that like results will some day be obtained from the male sexual glands. Thus far, it seems to me, that somewhere in the process of manufacture something is done which seems to destroy the active principle of the male glands, so that the extract is inactive, while in the case of female glands, the active principle remains potent to a degree. A new method of administration must be devised.

Practical Therapeutics

CHEMOTHERAPY IN EMPYEMA

WALTER ALBERT GEKLER, M. D.

Albuquerque, New Mexico

Medical Director of the Albuquerque Sanatorium

The purpose of this paper is to present our experiences of the past two and a half years in the treatment of pleural infections by nonsurgical methods. Most of the cases cited are tuberculous individuals in whom the empyema arose as a complication in artificial pneumothorax. We have made no attempt at chemotherapy of tuberculous empyema but have confined our efforts in this condition to simple drainage by repeated aspiration. We believe that the treatment of tuberculous empyema is mainly preventive; that is not allowing a tuberculous exudate to remain indefinitely in the thorax. In this connection we should like to take issue with the orthodox view concerning the treatment of exudates occurring in the course of artificial pneumothorax. It is commonly held that this exudate may be allowed to remain indefinitely in the chest without damage to the patient. In a large percentage of the empyemas complicating pneumothorax a preexisting tuberculous exudate seemed to provide the culture media for secondary organisms, and to invite the occurrence of empyema. After encountering a number of patients in whom secondary infection of the thoracic cavity had taken place, with its severe and alarming symptoms as well as protracted course, we have made it our practice to remove fluid from the chest whenever we may find it there in any more than minimal quantities. Since starting this practice we have not encountered any tuberculous empyemas, and feel that in certain patients this condition has been avoided by keeping the chest as free as possible of accumulated fluid.

Another reason for this course lies in the fact that pneumothorax is a mechanical method of treating tuberculous abscesses and cavities in the lung and if we are to have the success with this method of treatment which it deserves the pressure conditions in the pleural cavity must be under our control constantly. The habit of allowing fluid to remain in the chest and removing it only when urgent pressure symptoms demand it takes out of our hands entirely the control of the pressure and in some cases means ultimate failure in the treatment. It is well known that in some cases when fluid is present in the chest the lung will commence to reexpand, becoming adherent to the chest wall at some point where it is bathed with the exudate, and in spite of anything we can do the process of reexpansion will continue and make treatment for the proper period of time impossible.

In some of the cases briefly described in this paper we had to deal with spontaneous pneumothorax complicating artificial pneumothorax, at which time the infection of the pleural cavity with secondary organisms took place. In most of them, however, there were no signs or symptoms of spontaneous pneumothorax and the manner in which the pleura became infected still remains a matter of speculation. It is possible, of course, that infectious material may have been carried into the chest in the process of the routine injection of air. Again it is possible that an acute infection of the upper air passages extended by continuity to the pleura, causing a small subpleural abscess which ruptured into the pleural cavity. Again, infection may have been carried into the pleural space through the lymph channel during the course of a severe cold. (Not mentioned in the paper are two patients in whom a typical lung abscess developed in a partially collapsed lung following an acute infection of the upper respiratory tract.) A final possibility is that during the course of a severe cold microorganisms carried about in the blood stream might have lodged in the pleura, and with a culture medium at hand in the form of a sterile exudate, caused the empyema.

Surgical treatment of empyema complicating pneumothorax or pulmonary tuberculosis has a large mortality, and in those patients who do not die very shortly following the operation we frequently have an undesirable wound which will continue to discharge for an indefinite period. These wounds often become infected with saprophytic organisms, giving rise to exceedingly vile odors which are a source of extreme annoyance to the patient and those about him. The reason why surgical drainage with rib resection is not successful is that there is no way to get the collapsed lung reexpanded. A lung that has been collapsed for tuberculosis for a period of time does not have the elasticity of a normal lung. In chronic empyema in nontuberculous persons it is frequently found that the lung has not only lost its elasticity but is covered with a thickened, shrunken pleura. With atmospheric pressure being exerted down the bronchial tree, and also through the opening in the chest wall, there is no force favoring reexpansion. Drainage alone does not of necessity get rid of infection. In some of our pneumothorax patients we did not desire reexpansion of the lung because it was considered advisable to continue the collapse for the tuberculosis.

The technic employed in drainage of fluid from the chest has been, in our opinion, a great factor in whatever success we have had in this work. In order to empty completely the chest by aspiration, or otherwise, it is necessary to aspirate at the very lowest point, which, with the patient in an upright position, is impossible to do. Our method consists of placing the patient on the affected side, his body on one table and shoulders on another, with a space of six inches between the two tables. The chest is then punctured from beneath. In this way the side of the chest is made temporarily the lowest point—the logical point for drainage. Before the needle is withdrawn the patient is made to roll over on his back and the possibility of pus following in the needle's track and causing subcutaneous abscess is considerably minimized. X ray plates made of the patient before and after puncture show that the chest can be completely emptied of fluid in this manner

This technic is used for the removal of any kind of fluid from the thoracic cavity as a routine.

The ordinary Potain aspirator with its many connections and pump has proved an unsatisfactory instrument in our hands. When one has exudate to remove from three or four patients in an afternoon, as frequently happens in our practice, the laborious use of the hand pump which is part of a Potain equipment becomes exasperating. We have used a home made apparatus devised by the late Dr. A. G. Shortle, which so far as we know has never been described in print, and which has been more than satisfactory. An ordinary gallon bottle, usually one in which some drug has been purchased, is fitted with a rubber stopper through which a glass tube has been inserted. A piece of rubber tubing some fifteen inches in length is connected to this. A strong artery forceps is used to clamp off the tube. In creating a partial vacuum the bottle is rinsed with denatured alcohol and after standing a few minutes a match is applied, which results in a rather sharp explosion accompanied by a shooting of flame from the neck of the bottle. At this instant the stopper, with the tube clamped off, is quickly put in place and one has a sufficient negative pressure in a gallon bottle to withdraw two quarts of fluid from the chest. It is very seldom that one will need a larger capacity than this.

REPORT OF CASES

Case I.—L. H. S. was a sugar free diabetic who had been under treatment since December, 1919. A successful collapse had been achieved with symptomatic relief. Tuberculous exudate developed shortly after pneumothorax was begun but acute symptoms of this exudate subsided after a few weeks. Enough fluid was withdrawn to relieve any mechanical disturbance caused by displacing the heart, etc., and the rest of it was allowed to remain in the chest where it caused no discomfort or symptoms. Early in October, 1920, the patient contracted a severe cold from which he had not entirely recovered when he reported for his routine injection of air. He had a slight chill the day before his treatment. Two days later when I was called to see him he had a high temperature, dyspnea and a great increase in the level of the fluid which had been constant for a number of months. I took off enough air to relieve the dyspnea and cardiac disturbance and the next day removed by aspiration 1,500 c. c. of fluid which, on culture and smear, contained Staphylococcus aureus. Enough air was introduced to leave a slightly negative pressure. Drainage by aspiration was done as often as fluid accumulated, which in the beginning was every day or two. Lavage of the thorax with one or two litres of normal saline was done following removal of the pus. The temperature remained high and, along with it, the patient's general condition became steadily and alarmingly worse. In the dilemma an attempt was made by the injection of a neutral solution of sodium benzoate to inhibit bacterial growth, but this had to be discontinued on account of irritating the pleura as well as the entire lack of success. Next a neutral solution of anthranilic acid was tried—with the same result. (This compound shows a much more marked bacteriostatic and bactericidal action than the closely allied salicylic or benzoic acids. Its toxicity appears to be very low. Up to the present time we have not been able to demonstrate it in the blood following intravenous application. This may be due either to a lack of proper tests on our part or possibly, also, to a change in the compound which would make its detection impossible. Further work is under way with this material.) The aspirations were continued and our persistence was rewarded by some reduction in temperature and improvement in the general condition. At this time sugar reappeared in the urine and the temperature rose to its former level. Typical staphylococcic pus accumulated with the same rapidity as in the beginning.

Churchman's work on the sterilization of infected joints with gentian violet suggested the use of this compound in the pleural infections. In the absence of any accounts in medical literature of the use of this dye in the chest, or its possible toxicity when used in this way, it was thought wise to test the absorptive power of the pleura for anilin dyes by injecting methylene blue in the chest and noticing the time that elapsed before it appeared in the urine. From work done previously I knew that absorption from the healthy pleura is very prompt—the dye appearing in the urine in from thirty to forty minutes—and that this absorption from pleural cavities that had been the site of tuberculous exudates was greatly delayed—the dye sometimes not appearing for twenty-four to thirty-six hours. (In one patient the dye appeared in small quantities in the urine for a period of five weeks, and was demonstrable in the exudate during this time.)

The first injection of gentian violet results in the accumulation of a very thick, deeply stained fluid which is difficult to remove through an aspirating needle. It is our practice to dilute this with normal saline and then attach the aspirating bottle. As a rule injections of several ounces of saline will make it possible to get out twice this amount of material, when another injection of saline will have to be made. This procedure is continued until the chest is entirely empty. The first few aspirations following the use of the dye are very tedious and may take as long as an hour each. Mixed in with the material aspirated one often finds shreds which will block up the needle and have to be removed by the injection of saline. During this procedure care must be taken to avoid either too great intrapleural pressure by injection of too much saline or a sudden drop in the pressure by removal of too much fluid before air is introduced to replace it. It is also not wise to expect any marked change for the better following the first injection of the dye.

In this first patient the blue appeared in the urine sixteen hours after injection into the thorax and it was decided that the gentian violet could be safely allowed to remain for the same length of time. One hundred and twenty c. c. of saturated aqueous solution of the dye was injected following removal of the pus and lavage with normal saline. A slight improvement followed, with no reaction, pleural irritation or other symptoms. Two days later the process was repeated but the dye allowed to remain twenty-four hours. Since then we have never allowed the dye to remain less than twenty-four hours and usually allow it to remain thirty-six to forty-eight hours or longer. At the same time careful atten-

tion to the diet resulted in the disappearance of sugar from the urine and the patient again improved. Later, when the fluid was entirely clear a series of dietetic indiscretions resulted in another appearance of sugar in the urine and coincident with this, the empyema flared up with all its old intensity. The dye treatment was carried through faithfully until there were no further formations of fluid in the chest, either serous or purulent. There has been no further recurrence of the empyema despite indiscretions on the part of the patient, and his chest has been dry for over a year. A tuberculous process in the other lung has extended to the point where, together with his diabetes, it will probably end the patient's life shortly.

Case VII.—R. G., a physician who came into our hands in September, 1920, gave a history of having had a spontaneous pneumothorax in the left side eighteen months previous, with a low grade streptococcic empyema following. He was aspirated several times and the aspirations were discontinued after several dry taps. It was assumed that purulent fluid was no longer present. Our entrance examination revealed, in addition to a well marked ulcerative, tuberculous lesion in the right upper lobe, an area of absent breath sounds, flatness on percussion and other symptoms of fluid, extending from apex to base and from the midclavicular line to the posterior axillary line on the left. The x ray showed an intense white shadow corresponding to the area described. Having seen signs and x ray shadows such as this caused by a greatly thickened pleura we assumed that we had such a condition here, taking into consideration the history of repeated unsuccessful attempts at aspiration. The patient did fairly well until February, 1921, when there was a marked increase in his temperature and physical examination gave signs of pneumothorax over the area of supposedly thickened pleura. This was confirmed by x ray. Considering the history of a marked increase in the amount of sputum it was obvious that he had a bronchial fistula. Treatment with gentian violet was begun and the sputum was colored with the dye. During the course of treatment a needle track infection took place and we had not only a bronchial fistula but one through the chest wall to deal with. Routine treatment resulted in the closing of both fistulæ and the lung had reexpanded to within an inch of the chest wall when the patient decided to return to his home. He was warned against rib resection or any other treatment than that which was giving such satisfactory results. We heard later that contrary to this advice surgical drainage was done, followed by death in eight weeks.

Case XVIII.—R. K. had had influenza and pneumonia, complicated by empyema, in February, 1920. The empyema evidently was not discovered because drainage was not instituted and the patient gave a history of very suddenly expectorating over a quart of pus. From that time on this man expectorated an average of eleven cigar boxes of pus a week. He came into our hands the middle of November, 1921, and when first seen by us showed signs of hydropneumothorax on the right side. The general condition was very bad, with both feet and legs edematous. Temperature varied from 99.5° to 101° daily. Incessant cough and expectoration of very foul smelling pus completely destroyed any appetite for food and gave the patient little rest. At the first aspiration we removed two litres of pus which on culture contained such a large number of organisms that it was impossible to determine the one originally responsible for the empyema. Gentian violet solution was injected at once and removed the next day, together with another litre of pus. A few days later the dye was injected again, to be removed after forty-eight hours. Within ten days the exudate was serous and the use of the dye was discontinued. By this time cough and expectoration had ceased and they have not returned. The temperature dropped to normal and for the first time in fifteen months the patient could sleep undisturbed. Within three months there was no longer any fluid present in the chest. The patient developed a voracious appetite and gained over fifty pounds. After the fluid ceased to accumulate we tried by regular aspirations at two week intervals to pull the lung out to the chest wall. It was our practice to reduce the pressure in the pleural cavity as low as the patient could tolerate it but after six or eight months of this we found that it was impossible to stretch the thickened pleura and further attempts to bring the lung out were discontinued. At one time we considered the advisability of doing a thoracoplastic operation in order to make the chest wall fit the collapsed lung but the excellent general condition of the patient made us doubt the wisdom or necessity of such a procedure at this time and nothing further was done. It will be of interest to note how long a sterile pneumothorax may remain in the chest without causing any trouble. One seldom sees a more striking recovery than this patient has made.

Case XX.—L. B. developed a lung abscess following tonsillectomy for which he was operated on in Chicago in 1919. He came under our observation in the spring of 1921 with a discharging fistula on the right side opposite the fifth dorsal vertebra. Purely as an experiment a concentrated alcoholic solution of the dye was injected through the fistula into the abscess. The dye proved very irritating to the bronchial mucosa but the amount of sputum and discharge were so diminished by its use that the patient demanded that we continue it. After eight or nine injections of the dye the fistula through his back closed and he left Albuquerque in the fall of 1921 for another western city where he went to work. At the last report we had he was free of symptoms and enjoying good health. (This case is added to this series to show that direct application of the gentian violet to the purulent processes in the lung itself may be safely undertaken.)

Further work along this time will be reported in a later paper.

SUMMARY OF CASES*

Case No. Condition.	Infecting Organism.	Remarks.
II. Spontaneous pneumothorax complicating artificial.	Micrococcus tetragenus.	Lung reexpanded; patient working.
III. Pleural infection during severe cold.	Streptococcus.	Lung reexpanded; patient working.
IV. Mode of infection unknown. Pneumothorax patient.	Staphylococcus aureus.	Complicated with malaria; no results.
V. Pneumothorax patient. Mode of infection unknown.	Staphylococcus aureus.	Lung reexpanded; patient apparently well.

*Complete reports of these cases will appear in the author's reprints.

Case No. Condition.	*Infecting Organism.*	*Remarks.*
VI. Spontaneous pneumothorax complicating artificial.	Staphylococcus aureus.	Improved, but left community before treatment was concluded; result unknown.
VIII. Artificial pneumothorax. Mode of infection unknown.	Bacillus influenza?	Lung collapsed; sterile exudate; general condition good.
IX. Artificial pneumothorax. Onset of empyema during course of severe cold.	Staphylococcus aureus.	Lung reexpanded; patient working.
X. Artificial pneumothorax. Empyema followed cold.	Staphylococcus aureus.	Lung reexpanded; patient working.
XI. Artificial pneumothorax. Follicular tonsillitis.	Streptococcus.	Lung reexpanded; patient working.
XII. Artificial pneumothorax. Empyema during course of acute cold.	Streptococcus.	Lung reexpanded; patient apparently well.
XIII. Artificial pneumothorax. Mode of onset of empyema unknown.	Streptococcus.	Lung reexpanded; patient working.
XIV. Artificial pneumothorax. Mode of onset unknown.	Streptococcus.	Patient died of nephritis.
XV. Artificial pneumothorax. Empyema following severe cold.	Streptococcus.	Lung reexpanded but tuberculosis still active.
XVI. Artificial pneumothorax. Mode of onset unknown, probably lung abscess.	Mixed infection.	Complicated with malaria; patient died.
XVII. Spontaneous pneumothorax complicating tuberculosis.	Unknown.	Complicated with malaria; patient doing well, but not completely recovered.
XIX. Empyema following influenza pneumonia.	Streptococcus.	Lung reexpanded; operative fistula in chest wall healed; patient well.

SUMMARY

This work may be criticized from the point of view that possibly the results have been due to repeated and thorough emptying of the chest by simple aspiration and had nothing to do with the use of the dye. On the other hand, we have seen the temperature drop in twenty-four hours from over 104° to normal following one of the dye treatments, which would hardly take place with simple aspiration. Our patients, once the dye was used, demanded that its use be continued because they had universally felt better immediately after the gentian violet therapy was begun, and also complained about feeling worse when its use was not repeated frequently enough. It may very well be that the same persistence with ordinary aspiration and lavage would in a number of these cases have produced results. In many of them, however, the condition of the patient was rapidly growing worse and the patient himself would not tolerate attempts at treatment without the dye.

After this work had been under way for some time several reports of the use of gentian violet in empyema appeared, and we determined to withhold a report on our work until we had some end results to present. Cases II, III, V, IX, X, XI, XII, XIII, XV and XIX show definitely that a reexpansion of the collapsed lung can be brought about with obliteration of the pleural cavity so that recurrence of this condition is impossible. This was one of the points about which we were most anxious to have some degree of certainty before making any report.

Our experiences have shown us that gentian violet in any strength solution may be used with impunity to combat infections. In aqueous solution the dye seems to cause no irritation or destruction of tissues and in a period of two and a half years we have noticed no deleterious effects, either locally or constitutionally, from the liberal use of this dye.

Fortunately most of the infections with which we have to deal in the pleural cavity are caused by gram positive organisms. This was almost universally the case in our series. We feel satisfied in our own minds that the possibility of empyema need no longer deter any of us from using pneumothorax therapy, as in by far the larger percentage of cases this complication may be successfully treated. The coexistence of malaria and secondary infection in the chest is a vicious one and should be watched for constantly.

The existence of bronchial fistula or operative or accidental fistulæ through the chest wall are not only not contraindicative to chemotherapy but seem to be an indication for it. We have reached the conclusion that when the infective organisms are killed prompt healing of the fistulæ occur. It is difficult to conceive of a more nearly ideal method of achieving this result than by the use of some potent chemotherapeutic agent such as gentian violet.

THERAPEUTIC NOTES

CHARLES GREENE CUMSTON, M.D.
Geneva, Switzerland

TREATMENT OF LEPROSY

News has recently come to hand from Indo-China of continued favorable results obtained in the treatment of leprosy with intravenous injections of Chaulmoogra oil and an emulsion of the oil taken *per os*. After considerable clinical experience, Lamoureux has found that the exhibition *per os* of Chaulmoogra oil in emulsion in a normal soda solution in no way decreases its efficacy and is advantageous in that it is well tolerated by the digestive tract, so that considerable amounts can be taken for a long time—more than ten c. c. a day. The intravenous injection of the emulsion is more active in the acute phases of the disease and may bring about retrogression without ulcerations or intense congestive lesions. The continued use of the drug will keep the leprosy in check for more than two years, which is longer than the phases of latency usually observed in the ordinary evolution of the disease. If the drug is stopped, thus allowing the affection to run its course, acute accidents are prone to develop, so that it is essential to keep the organism impregnated with the drug, while at the same time no danger from accumulation need be feared.

By using progressively stronger percentages—three per cent., six per cent., twelve per cent., and twenty-five per cent. of the emulsion—Lamoureux has been able to reach much higher doses than those given by Noc and Stevenel. The only untoward occurrence incident to intravenous injections is early nitritoid crises—similar to those arising with the arsenical preparations, characterized by a temperature of 30° to 40° C. (102° to 104° F.) and severe chills, followed by sweating, but these crises may be prevented by previously injecting three or four drops of a one to 1,000 solution of adrenalin.

TREATMENT OF SLEEPING SICKNESS

Details have recently been given by the Belgian Ministry of the Colonies of the results of recent experiments made on the Congo in regard to the treatment of sleeping sickness with the new product

"205." This has been carried out in the Belgian Congo by Dr. Walravens, chief of the laboratory at Elizabethville, who has been assisting Professor Kleine in the district of Lake Noero, and Dr. Van den Branden and Dr. Van Hoof, who have been experimenting at Leopoldville for over a year. The results obtained have been favorable.

The new product has an advantage over atoxyl and hemetic in giving the subject a longer immunity against the action of the specific bacterium. Fewer injections are necessary, two or three being as a rule sufficient, while of atoxyl eight or ten are required. It has not yet been demonstrated that the remedy is of the same efficacy in the case of patients in the second phase of the disease. In the third phase, and when the bacteria have penetrated to the central nervous system, it has no effect. Though "205" has proved to be a useful remedy, there is room for improvement, while its use is not without danger, for it may cause renal disturbances.

I would add that another product, produced by the Rockefeller Institute—tryparsamid—has been experimented with by Dr. L. Pearce. Her work, which has been followed with attention by the Belgian physicians, appears to have given interesting results, but this product may give rise to unfortunate consequences for the eyes.

THYROID MEDICATION IN ARTHRITIS DEFORMANS

At a recent meeting of the Paris Medical Society, Dr. L. Lévi reported the case of a female, sixty-three years of age, presenting an arthritis deformans of the left knee that had been present for twenty years. The joint was greatly enlarged and deformed, while the skin covering it contained large varicose veins. Movement was difficult and painful. Lévi finding that the patient was a thyroid subject, exhibited thyroid medication with the result that improvement began the first week; the circumference of the knee decreased, likewise the pain and cracking of the joint, while the patient was able to walk as she had not done for years. From these immediate results the medication became a means of diagnosis just as myxedema.

Among the thyroid signs presented by this patient was complete absence of eyebrows. Upon the administration of thyroid medication these at once began to grow, while the hair, which had been falling out, began to grow and the patient, who was obese, lost weight. Recalling other cases in which the patient became more youthful in appearance, Dr. Lévi supposes that in the complex problem of early senility, or even when physiological, if the various glands—including the genital glands—play an unquestioned part, a foremost place should be given the thyroid. From the physiological viewpoint, it was pointed out that the hands and feet were hot, the face congested, the eyes brilliant and oppression marked. Five milligrams of powdered thyroid were given four times daily the first week, but afterwards, on account of the nervousness and excitement produced, only six doses were given a week.

The patient's son was also treated for numbness of the right ring finger, spasmodic asthma, asthmatiform crises, stiff legs, pain in the hands, gastrointestinal disturbance, dry eczema of the legs, startled sleep, and poor general health. Thyroid medication completely transformed this patient, who said he had become ten years younger; but as in the case of the mother, the decrease of memory, high blood pressure, and tachycardia did not improve. Lévi thinks that these cases confirm thyroid heredity.

HYPERGLYCEMIA PRODUCED BY ADRENALIN TEST

Since we are on the subject of the endocrine glands, I would say that Professor Labbé, of Paris, recently read a paper before the Biological Society of Paris, in which he stated that an injection of one milligram of adrenalin in cases of Basedow's disease usually produced hyperglycemia and a higher pulse rate than that obtained in normal subjects. Blood pressure is not usually increased, while the oculocardiac reflex is inverted in all cases, but there was no glycosuria, local reactions, or subjective disturbances. In sympathicotonic subjects the adrenalin test does not usually give rise to marked hyperglycemia; on the other hand, the blood pressure increases, likewise the pulse rate with inverted oculocardiac reflex. This test distinguishes sympathetic disturbances from those due to endocrinosympathic disturbances, otherwise Basedow's disease.

PHENOLSULPHONEPHTHALEIN TEST IN PROSTATECTOMY

Negro and Colombert have recently stated that in their opinion the phenolsulphonephthalein test is superior to any other as a prognostic indication of prostatectomy. To the data obtained by this test it is of course necessary to add the results obtained from examination of other viscera in order to eliminate any other contraindications for this operation that may offer themselves, independently of a good renal function. The phenolsulphonephthalein test only gives precise data in respect to the ureic function of the kidneys, these being less exact when some circulatory lesion coexists. The test is advantageous in that it is simple. Operation can be safely done if at least forty-five per cent. of the drug is eliminated during the first hour following its intravenous introduction, otherwise prostatectomy is contraindicated.

UNEQUAL PUPILS

In a recent very excellent study (*Thesis,* Paris, 1923) Dr. W. Jullien finds that if all anisocories due to lesions of the cornea or intrinsic ocular lesions are eliminated, cases of unequal pupils can be divided into two classes, namely—small and large unequal pupils. The first are discreet and will be overlooked if not sought for; they are fleeting, appearing one day and disappearing the next, only to be found later on perhaps with a different aspect. The reflexes remain normal. Tuberculosis is to be incriminated in the same way as many other pulmonary or general affections. Large unequal pupils are usually striking, hence their diagnosis is easy and being permanent, they are found at each successive examination without any change. They are usually accompanied by a change in the reflexes. Pulmonary tuberculosis is rarely the cause, syphilis occupying the all important place in the genesis of these anisocories, and to a lesser extent those affections acting on the parasympathetics or their nervous origins. Although Jullien admits that this distinction is somewhat schematic, it nevertheless covers the great majority of cases.

Historical Medicine

Thomas Paine on Yellow Fever

G. ARBOUR STEPHENS, M.D.,
Swansea, England
Consulting Cardiologist to King Edward VII, Welsh National Memorial Association

Writing in 1806 the great English-American-Frenchman, Thomas Paine, tells us that "A great deal has been written respecting the yellow fever . . . and what I am going to suggest in this essay is to ascertain some point to begin at in order to arrive at the cause."

Sound philosopher as Thomas Paine was, it is no wonder we find him searching strenuously for the cause of this disease, so as to understand the fundamental principles associated with, or underlying, a disorder which had far more devastating effects than either the Anglo-American war or the French Revolution.

Paine, who had fought so hard to establish the American Republic, and whose hand is to be seen so plainly in the phrasing of the Constitution, was gravely concerned at the fearful epidemics which were being attended by such a very high mortality.

Matthew Carey gives us but a faint idea of the state of things in Philadelphia in 1793 when he tells us that out of a population of forty thousand over four thousand persons died from this terrible disease.

Other epidemics occurred in 1798, 1799, 1802, 1803, and 1805, and in 1806 Paine published his essay "as belonging to natural philosophy rather than medicinal art, and therefore I say nothing about the treatment of the disease."

Paine was no quack; he appreciated the difference between the science and the art of medicine—a difference that deserves to be emphasized properly in these days, of pseudoscience, when vaccines are boosted out of all proportion to the benefits which can possible accrue from their use. It may interest readers to know that it was no uncommon practice for philosophers in the seventeenth and eighteenth centuries to take an active part in connection with medical as well as other sciences, for as I pointed out in *The Practitioner* for February, 1924, "The Invention of Injection into the Veins is given to Sir Christopher Wren."

The Hon. Robert Boyle has a paper on queries and trials proposed to Dr. Lower, to be made by him for the improvement of transfusing blood out of one live animal into another." It strikes one oddly to find Sir Christopher Wren, the great architect, proposing experiments which anticipated our modern methods of treating syphilis by over two hundred years!

The Hon. Robert Boyle, who as director of the East India Company took important steps in connection with the propagation of Christianity in the East, was a great scientist, and founded with Wren and others the Royal Society of London.

To enable us the more adequately to appreciate Paine's efforts in elucidating the mystery associated with yellow fever, it may be worth while quoting an authoritative statement made as late as 1900.

"Negroes and Mongolians are little susceptible to yellow fever, and it is noteworthy that strangers are the more liable to be attacked, the farther north or south from its area they have been born."

"New arrivals are more liable to contract the disease."

"The area of distribution is limited to the sea coasts, and banks of the great rivers."

"For the production of yellow fever a dense population is necessary, as also a temperature of above 70° F., a moderate amount of moisture in the atmosphere, and a low altitude."

"The yellow fever poison can be transported further by sea than on land, and may be carried by clothing, bedding, etc., which may retain the poison for a very considerable time."

Thomas Paine tells us that "Yellow fever always begins in the lowest part of a populous mercantile town near the water, and continues there without affecting the higher parts. The sphere or circuit it acts in is small, and it rages most where large quantities of made ground have been made by banking out the river for the purpose of making wharfs."

"The appearance and prevalence of the yellow fever in these places being those where vessels arrive from the West Indies, has caused the belief that the yellow fever was imported from there."

"Here," says Thomas Paine, "are two causes acting in the same place: the one the condition at the wharfs which being new made on the muddy and filthy bottom of the river is different from the natural condition of the ground in the higher part of the city, and consequently subject to produce a different kind of effluvia or vapor: the other is the arrival of vessels from the West Indies."

He goes on to point out that in the State of Jersey there was no arrival of shipping and consequently no necessity to build wharfs. "This," he adds, "does not decide the point, as to the immediate cause of the fever, but it shows that the species of fever is not common to the country in its natural state."

The disease seems to have been described for the first time about the year 1647 when it was encountered in the West Indies to which parts together with the adjacent coast of North and South America it seems peculiar.

It may be of some interest to know that the town in which this article is written, namely Swansea, is the only one in Great Britain where an epidemic has occurred.

The trade at that time, 1856, between Swansea and the West Indies was very considerable, a large fleet of specially designed boats being actively engaged in the copper ore trade.

Most probably the mosquitoes were imported together with some very mild cases, and on arrival the

insects were quick to detect individuals ready to respond to their vicious bites. These specially built boats were good craft and covered the distances under favorable circumstances in a very short time.

A friend of mine who served on that trade tells me that he covered the distance from here to the Barbadoes in thirteen days—a period well within the time necessary for the full development of the organism together with the incubation period of the disease in a person leaving the West Indies in a fit condition. This friend points out that there were more cases of yellow fever in wooden than in iron boats and also that there was more bilge water in the wooden boats than in the iron craft, so that if the larvæ required such opportunities for development, they were supplied to the full extent in the wooden boats.

He also informed me that it fell to his lot "when everybody else had fled," to look after the second mate who was ill with yellow fever. They occupied the same cabin, he sleeping in the upper berth so as to be at hand in case of any emergency. They were treated as lepers, their food being handed in at the end of a pole.

Fortunately for him mosquitoes did not bite him, or even if they did the effect was trifling, though all the crew had their eyes nearly "bunged up."

For prevention he always took quinine and a lime squeezed into a glass of water, while he was very careful about the evacuation of his bowels.

Thomas Paine seems to have been interested in the history of the disease, but finds that "no old history, that I know of, mentions such a disorder as the yellow fever."

One interesting point he seems to be very definite on, and that is: "A person seized with the yellow fever in an affected part of the town, brought into the healthy part, or into the country and among healthy persons, does not communicate it to the neighborhood or to those immediately around him."

A statement of this sort clearly anticipates the finding of the Yellow Fever Commission of the United States Army, which discredits the belief in the transmission by fomites.

This philosopher concludes that if the disease be not spread by contact when cases are moved into the higher reaches it is absurd to blame the West Indies at a distance of more than a thousand miles as the great distributing centre for the American coast merely by contact.

Thomas Paine satisfies himself therefore that:

"First, the yellow fever is not a disorder produced by the climate naturally, or it would always have been here in the hot months; the climate is the same now as it was one hundred years ago; there was no yellow fever then, and it is only within the last twelve years that such a disorder has been known to America.

"Secondly, the low grounds on the shores of the rivers, at the cities, where the yellow fever is annually generated and continues for about three months without spreading, were not subject to that disorder in their natural state, or the Indians would have forsaken them; whereas they were the parts most frequented by the Indians in all seasons of the year, on account of fishing."

He is impressed by the fact that some new "circumstance" as he calls it has been introduced, and forthwith proceeds to find out what it is. The coming of the white people, their building of towns, their clearing lands, levelling hills and filling up valleys are, he points out, "all new circumstances which are unaccompanied by yellow fever. No alteration," he adds, "made on dry land produces the yellow fever; we must therefore look to those alterations that have taken place between wet and dry, between land and water."

At the period when Paine was writing great alterations had taken place along the shores of the rivers at New York and also at Philadelphia on account of the rapidly developing commerce in those parts; for this commerce a large amount of work had been done and the ground very considerably disturbed in order to erect wharves to discharge the shipping. "It is only in such parts of the shores where these alterations have taken place that the yellow fever has been produced. The parts either on the East or the North River where no alteration has taken place do not produce the yellow fever."

He gives us this further interesting information: "Besides several new streets gained from the river by embankment, there are upward of eighty new wharves made since the war; the consequence of which has been that great quantities of filth and combustible (sic) material deposited in the muddy bottoms of the river contiguous to the shore, and which produced no ill effect while washed twice every twenty-four hours by the tide water, have been covered up with new earth and pent up and the tide excluded. *It is in these places, and in these only, that the yellow fever is produced.*"

I have italicised this last sentence in order to show how very definitely Paine seems to have localized the trouble and how very near to the whole truth he had arrived.

The history of medicine contains several instances of close approximations to the truth, the actual arrival being delayed for centuries. About the most striking instance of this is to be found in connection with Harney's discovery of the blood, for Aristotle makes statements in his works suggestive of, if not actually referring to, a circular movement.

Having definitely localized the spots, or disease spreading centres, Thomas Paine tells us that "the impure air or vapor that generates the yellow fever issues from the new made earth or ground raised on the muddy bottom of the river, and which impregnates every fresh body of air that comes over the place as when air becomes offensive in smell when it passes over vegetable or animal matter in a state of putrefaction."

"The muddy bottom of rivers contains great quantities of impure and often inflammable air (carburetted hydrogen gas) injurious to life and which remains entangled in the mud till it be let loose."

In connection with this inflammable gas Thomas Paine describes some experiments he carried out with General Washington and General Lincoln in the year 1783, when Washington had his headquarters at Rocky Hill, New Jersey.

"A scow had been stationed in the mill dam, and General Washington, General Lincoln, and myself, together with three or four soldiers with poles were put on board. General Washington placed himself

at one end of the scow, and I at the other: each of us had a roll of cartridge paper, which we lighted and held over the water.

"When the mud at the bottom was disturbed by the poles, the air bubbles rose fast, and I saw the fire take from General Washington's light and descend thence to the surface of the water."

Thomas Paine having arrived at such a definite conclusion thinks he ought to make some suggestion in order to prevent the recurrence of these epidemics. His great idea is to give up covering up the mud and to build the wharves by means of stone arches so as to allow of the mud being washed by the tide twice a day.

The length of Thomas Paine's disquisition on yellow fever is in marked contrast to the short and poverty stricken ideas of the "Authorities" writing one hundred years afterwards. Had his work been followed up by scientifically minded medical men one feels certain that the truth would have been discovered much earlier than it was.

The tendency today is to imagine that our predecessors were very limited in their ideas, but the more one consults the ancient folios the more one is convinced that they contain truth nuclei of very great value, which only requires to be cleverly handled to give us revelations beyond our wildest dreams.

Mendel, the Apostle of Heredity

CHARLES A. CLOUTING, M.D.
London

Of the very great men, that is, men of original genius, who failed to come into their own during life, in modern times Mendel is easily the most conspicuous example. His theories, or rather the wonderful facts he worked out with regard to heredity, and which should have rightly placed him on a pedestal with Pasteur, Galton, and Darwin, were forgotten and not known to the scientific world for years after his death. It is no exaggeration to say that Mendel's discoveries were epoch making and opened a new era in the science of heredity.

Johan Mendel, like Pasteur, was of humble origin, his father being a small peasant proprietor much interested in fruit culture. He was born in Austrian Silesia in 1822, in the same year as Francis Galton, the great British student of heredity. When he was twenty-one he was admitted as a monk into the monastery of Brünn in Bohemia, and was given the name of Gregor. In 1851, having manifested a great gift for scientific work, he was sent by the religious order to which he belonged to the University of Vienna, where he studied physics and natural science. Returning to the cloister, he acted as a teacher of science in the Realschule of Brünn, occupying his spare time in making experiments with peas and other plants in the garden of the monastery. In so doing, he made his great discovery with regard to heredity, and reached the very important conclusion, i. e., the rule, referred to briefly as Mendel's law. In 1866 this was published in the *Proceedings of the Natural History Society of Brünn,* but it was never heard of outside this place, for the remainder of the century. It was not until 1900 that DeVries in Holland, Correns in Germany, and Tschermark in Austria, unearthed Mendel's work and confirmed it.

Mendel was a remarkable man in many directions, an able teacher, a good man of business, a keen chess-player, and an investigator with an infinite capacity for taking pains. He was an earnest experimenter. Mendel made observations on heredity in bees, and it is especially to be deplored that no papers bearing on this branch of research have been found. He had fifty hives in the garden of the cloister and experimented in the crossing of queens of different species. It has been suggested that Mendel may have destroyed any notes he made, amid the disappointments of the later years.

According to Professor J. Arthur Thomson, there are three foundation ideas in Mendelism. The first is the idea of unit characters, that the inheritance in part at least is made up of numerous more or less clear cut, crisply defined, nonblending characters, which are contained in some of the descendants as intact items, without merging and without dividing. If a man has his fingers all thumbs, with two joints instead of three, this unit character of brachydactylism will be continued in a certain proportion of his descendants. Since the reign of Charles I, some of the descendants of one Jean Nougaret have shown the peculiarity known as night blindness, "the inability to see in a faint light." The long persistence of the Hapsburg lip in the royal houses of Austria and Spain is well known. Sometimes the character is quite trivial, as, for instance, a lock of white hair. Sometimes it is very important, as, for example, a tendency to bleeding in males. The unit characters have their representatives in the nuclear rods or chromosomes in the egg cell and sperm cell, and these representatives are called factors, or genes, or determinants.

The second big idea in Mendelism is dominance. If a Japanese waltzing mouse, with its constitutional peculiarity of dancing round and round on the slightest provocation, is crossed with a normal mouse, all the offspring are normal. This is technically expressed by saying that the waltzing characteristic is recessive, while normality is dominant; but one cannot tell beforehand whether a given character will be dominant or recessive. When the hybrid, apparently quite normal mice are inbred, their offspring show twenty-five per cent. of pure waltzers and seventy-five per cent. of normals. If these waltzers of the second filial generation are bred with others like themselves, they produce only pure waltzers. If the normals of the second filial generation are inbred, a third of them will produce pure normals, but the after two thirds will produce normals and waltzers in the previous three to one ratio. This is the Men-

delian rule. One might sell one of the second filial waltzers as a pure waltzer, though its parents were normal, as also was one of its grandparents.

There may be mentioned half a dozen examples of characters which show Mendelian inheritance, placing the dominant first in each case; hornlessness and the presence of horns in cattle, normal hair and long angora hair in rabbits and guineapigs, crest and no crest in poultry, bandless shells and banded shells in the woodsnail, tallness and dwarfness in peas—it was with peas that Mendel made his classical experiments, susceptibility to rust and immunity to this disease in wheat. But no one knows why one character should be dominant and another recessive. At the beginning of each individual life when the egg cell is fertilized, usually an equal number of hereditary items is contributed by each parent. If one of the parents has a dominant character, like a tendency to early cataract, which the other parent has not, the unfortunate probability is that the offspring will show the dominant character. Mendel supposed that the offspring produced in equal numbers two kinds of germ cells, one contingent with, and the other contingent without, the factor or gene for the dominant character. Now, if the said offspring should marry another with similar history, the likelihood is that three fourths of the grandchildren would show the tendency to early cataract.

Professor Thomson points out that there may be other modes of inheritance besides the Mendelian mode. Thus blending may occur in some cases, but every year sees a further demonstration of Mendelism, and the discovery has put into the hands of breeders and cultivators a method by which desired results can be reached both quickly and surely. Heredity has made a great stride towards becoming an exact science.

The modest unassuming and unknown Abbé Mendel, who passed his life in the out of the world little town of Brünn, was one of the great discoverers of the world. He showed the way to a goal which although it has not been quite reached, has yet in its results been most wonderful and beneficent. To breeders and agriculturists it has been of the greatest value and it has blazed the trail to further discoveries in human heredity which may almost revolutionize medical science.

Mendel's law is an argument in favor of diathesis, or the inheritance of a susceptibility to certain diseases or conditions of body or mind which were dominant in a parent or an ancestor. If the influence of diathesis is accepted in its entirety, prevention of certain diseases or conditions will be rendered more easy, and even treatment will be facilitated. Although Mendel during his life was obscure, probably not even appreciated by those among whom he lived and worked, he will be acclaimed by posterity as one of the brightest lights of the age.

Contributors to the Science of Medicine

PAUL EHRLICH

Paul Ehrlich was born on March 15, 1854, at Strehlen in Silesia. Although he came of a family that had already contributed a number of celebrities to science, among them the famous Karl Weigert, who was a cousin of Ehrlich, the latter was but an indifferent student at school and later at the University of Breslau, where he received his academic education. When he went to the University of Strassburg, however, to take up the study of medicine and where he was able to devote himself to the lines of work in which he was most interested, his true abilities manifested themselves at once. After obtaining his degree in medicine at this university, he went for further study to the universities of Leipzig and Freiburg. Here he further specialized in the study of the application of chemical principles to animal pathology, along which line were made most of his contributions to science. When he had established himself in his specialties, he was made privatdocent and later professor at Berlin University, and finally was appointed to the enviable position of assistant in Koch's Institute. In 1896 he became director of the newly founded Institut für Serumforschung at Steglitz, which was later transferred under his direction to the Institut für experimentelle Therapie at Frankfort on the Main. Biographers usually divide his life into four periods according to the development of his work: 1, 1877-1890, devoted chiefly to the study of chemistry and experimentation with aniline dyes; 2, 1890-99, study of toxins, the chemistry of immunity, the development of the sidechain theory; 3, 1899-1906, study of hemolysins, malignant diseases in rats and mice, and completion of the sidechain theory by the theory of amboceptors; 4, 1906-1915, study of chemotherapy, especially in the treatment of trypanosomiasis. Ehrlich is best known as the discoverer of salvarsan, or 606. He was also the founder of hematology, and the pioneer of *Farbenanalyse* or the microchemical relation of the tissues to dyestuffs. An idea of the indefatigability of his brain may be gained by the fact that, between the years 1877 and 1914, he is said to have contributed 212 papers and books to the literature of science and to have inspired the composition of more than four hundred publications by his subordinates and laboratory workers. He was of course indirectly responsible for the printing of thousands of original articles by chemists, clinicians, and experimental pathologists the world over. He died on August 20, 1915, another of the great victims of the World War, the cruelties of which preyed on his mind and which he found hard to believe possible. He was the recipient of many scientific honors from all the countries of the world, among them the sharing in 1908 of the Nobel Prize in science with Metchnikoff. The Rockefeller Institute made grants for

some of his researches, and he delivered a series of the Herter Lectures in Baltimore.

This outline of Ehrlich's scientific career throws almost no light on the man's personal life; in fact, little was ever known about his private life except to a few of the most intimate of his colleagues. He married Hedwig Pinkus, daughter of Privy Commercial Councillor Pinkus, and the couple had two daughters, both of whom married German scientists. In 1888, he was threatened with phthisis and had to leave his work for a time to travel in Egypt in the effort to regain his health. Thanks to treatment with Koch's recently invented tuberculin, he recovered. His life was limited so entirely to his work and in this he was so untiring and indefatigable, with almost no relaxation, that, had it not been for the solicitous care of his devoted wife, he would doubtless have died much earlier than he did. As it was, his death from heart trouble came at the height of his scientific activities and, had he been spared some years, probably more great contributions would have been made by his genius to medical science. One of his biographers compares the brilliant, never resting mind of Ehrlich to "a sharp sword that ever tended to wear through the scabbard." He was always intensely preoccupied and absent-minded about everything in life except the immediate problem at hand. He had a tremendous power of concentration almost uncanny in its force and in its capacity to eliminate trifles, a quality which would have quite unfitted an average man for the ordinary affairs of life.

PROFESSOR EHRLICH IN HIS STUDY
(Courtesy of the *British Medical Journal*)

In a recent issue of *Medical Life,* A. L. Wolbarst writes interestingly about his personal reminiscences of Ehrlich. Wolbarst, accompanied by his wife, had gone in 1910 to the Institute of Experimental Therapy at Frankfort to study the then new remedy for syphilis, 606. He describes their arrival at the institute's waiting room, a large foyer bare of furniture and much in need of a coat of paint.

Through a letter of introduction, the Wolbarsts were admitted to the great man's inner sanctum, and the meeting is described as follows: "Seated in an old arm chair in front of a desk covered almost to the ceiling with papers, books, cigar boxes, stumps, matches, and various other articles, we saw a kind-faced, fatherly old man, probably sixty or more. He was reading my letter of introduction. Round about him were a few chairs and settees, all of which were similarly piled high with unopened mail, magazines, and books, all covered with a coating of dust that was glorious to behold. . . . As soon as he saw us he quickly arose, and asked us to be seated while he continued reading the letter. . . . At last he broke the spell by taking a cigar out of the box which lay near by and offering it to me. . . . It did not take long to plunge into conversation with this most charming man. He asked questions innumerable about New York and mutual friends in New York, and he recalled with pleasure his visit to our city some six years previously, referring particularly to the 'Flatironing' building where he bought 'those delightful cigars.'" An incident is recounted showing the great sensitiveness of Ehrlich to criticism. His secretary read to him one morning an attack on 606 by Gaucher. The great scientist was much distressed and wept. "All my life," he sobbed, "I have given to this work, and now they abuse me!" Wolbarst describes Ehrlich as a man fond of the country while on his brief and rare vacations, cordial and friendly with those he knew, of great simplicity and sweetness of nature, broad-minded and liberal in viewpoint, finding good in all and loath to find fault, with an appreciation of real values in life and people, and faultless as a host. "He always was eager to get the American viewpoint; he had a high regard for American physicians and American medicine generally."

Ehrlich's writings showed great felicity of expression. He had a genius for the creation of descriptive phrases such as his famous *"Corpora non agunt nisi fixata."* He was fond of expressing his ideas in symbols and diagrams. C. H. Browning writes of him in the *British Medical Journal:* "Were I to attempt to characterize the genius of Ehrlich, I should say that it consisted in two striking characteristics: his faculty of escaping the trammels of error in past work, and his capacity for bringing into association as the basis for experiments ideas which purely critical minds would tend to dismiss as fantastic." Browning goes on to say that he believes this man, whose practical contributions to medicine have been so numerous, probably never approached any problem in a utilitarian spirit. "Pure science," writes Browning, "frequently stand in need of apologists, and Ehrlich's whole career is a striking vindication of the pursuit of knowledge for its own sake. He who seeks, finds; and Ehrlich was an inspired seeker."

Editorial Articles

A NEW CATEGORY

Human characteristics have had various groupings. In medicine the study of man has long been pursued under the heads of anatomy and physiology. Pigeonholing by mental traits has seemed of less service, though the grouping into "sanguine, phlegmatic, bilious, and melancholic" was as distinctly psychological as it was physical, and it was only a generation ago that this grouping was revived by some psychologists and the physical features of each type pointed out.

Classification by constitution or diathesis, with reference to special diseases, has been attempted, though with much haziness of conception. Of late it has been little mentioned. In an attempt at a revival of interest in this subject and of putting the subject of constitution and disease on a more sharply defined basis of measurement, Draper, Dercum, and Seegal have been making some studies. The results of these efforts, so far published, are of considerable interest. They have at least added one more heading for human classification, or rather have separated one item into a more outstanding feature, that of reaction to bacterial infection. They group our traits into "four panels of personality"—morphology, physiology, psychology, and immunology.

Hitherto, reaction to bacteria has been considered as to some extent linked with anatomical structure—at any rate, tuberculosis has been so connected, and we have had the "phthisical constitution," "the phthisical chest," and other diagnostic phrases which have grown out of clinical comparisons. Perhaps it has not been taken into account, in this connection, that tuberculosis is not an acute disease and that the bodily type was as much the result of the disease as the disease the consequence of morphological type. At any rate, most of us have had the disease, diathesis or no diathesis.

The mechanism of resistance to infection is, of course, a physiological one, just as the reactions to environment which we call mental are also physiological. Both psychology and immunology rest on an anatomical basis, yet the brain, in structure and function is so little related (save perhaps in extreme cases) to other attributes that no comparison can be drawn. Spinoza, Descartes, Kant, Mill, all had marvelous brains, but they were as distinct in outward bodily traits as if they belonged to different varieties of the species. Chopin was of the tuberculous diathesis (if there is such a thing). Beethoven was of the apoplectic order. Balzac and Stevenson were at opposite anatomical poles.

Immunologically, there is as wide a variation in men. Washington and Lincoln were both athletes as well as statesmen of a high order; one had many attacks of malaria, dysentery, influenza, etc.; the other is said to have never been sick.

Anatomical and physiological traits are chiefly hereditary; so, too, are mental features, at least in general, but with apparently little reference, by descent, to the former factors. Immunological traits are also closely bound up with heredity and seem equally independent of measurable bodily features; however, we shall be glad if the investigators who have taken up this interesting subject will discover some definite anthropometric relationships which may be of help in clinical medicine.

THE TREATMENT OF GASTRIC AND DUODENAL HEMORRHAGE

Perhaps in no other condition has there been so wide a divergence of opinion regarding treatment as in severe gastric and duodenal bleeding. The physicians have held firmly to the view that medical measures are almost universally indicated and that to operate when severe hemorrhage was going on was directly contrary to sound practice. At a combined meeting of the Sections of Medicine, Surgery, Therapeutics, and Pharmacology of the Royal Society, held in London on March 5th last, a paper on this subject was read by H. J. Paterson and gave rise to considerable discussion. Although a surgeon, Paterson took the stand that surgical treatment of acute hematemesis was unjustifiable, but as his paper appears in this issue, it is superfluous to run through his arguments, which, stated briefly, are that in treating cases of hematemesis, inaction is often the wisest and possibly the only safe course, although always the most difficult.

In the discussion which followed, divergent opinions were expressed. Sir William Willcox drew attention to the risks attending the administration of morphine, pointing out that patients suffering from cirrhosis of the liver, alcoholic or syphilitic, were peculiarly susceptible to the toxic effects of the drug, and the same held good with chronic nephritis. He thought that the giving of morphine hypodermically as a routine practice in cases of gastric and duodenal hemorrhage should be discouraged. It was a good plan to promote the coagulation of the blood by giving calcium salts in the manner advocated by Vines and Grove. In long continued symp-

toms, he believed, as a rule, in operative measures. A. F. Hurst was strongly in favor of medical measures, stating that he had only once had occasion to call in a surgeon to save the life of a patient suffering from bleeding from a gastric or duodenal ulcer. R. P. Rowlands had faith in radical operative measures, while Izod Bennett thought that the immediate treatment of these cases should be left entirely to the physician.

In the discussion, the surgeons advocated operation, and the physicians for the most part, medical treatment. It was generally agreed that old sclerosed gastric ulcers with a history of chronic pain and thickened vessels should be treated surgically. Some of the surgeons thought that if operation were undertaken at all on a bleeding gastric ulcer, it must be a direct and drastic attack on the ulcer, its separation from pancreas or liver, and its destruction either by excision or cautery. It was pointed out that in hemorrhage from a duodenal ulcer there was a much greater tendency to early and repeated recurrence of the bleeding, and consequently it was more immediately serious than gastric ulcer.

The point held by Paterson was that operation should not be undertaken during acute hemorrhage, but that the interval between the hemorrhage and the operation should be at least three months. Statistics seem to be on his side.

The question of whether to operate during severe hemorrhage from gastric or duodenal ulcer is important, and it would be instructive to obtain the opinions of surgeons and physcians in this country on the subject. Sir Berkeley Moynihan is averse to medical treatment, and according to two articles on gastric and duodenal ulcer issued recently from his pen, the operative mortality is low. But there is much to be said for Paterson's contention that it is dangerous to operate when a gastric or duodenal ulcer is acutely bleeding. It may be pointed out that Paterson holds that in chronic or recurrent hematemesis operation should, as a rule, be deferred for two or three months after the last hemorrhage, according to the condition of the patient. It is well that this matter should be discussed from all angles, as it is only in this way that even an approach to an agreement can be arrived at.

It may be added that at a meeting of the Surgical Section of the Royal Academy of Medicine in Ireland, held on February 29th last, James Sherren, one of the best known surgeons of London, gave an address on disease of the stomach and its surgical treatment, in which he laid stress on the need for recognition and thorough medical treatment of acute ulcers, in order to prevent the chronic type. In acute cases, with hematemesis, he said an operation should never be performed.

THE USE OF ANIMALS IN TEACHING NUTRITION

Although it is a well known fact that, because animals and man are so different, laboratory results obtained through animals cannot always be taken as criteria for human conditions, yet it has also been proved that, given comparable conditions, valuable deductions can be drawn about man from animal experimentation. This applies especially to the subject of nutrition, a subject in which just now there seems to be a widespread popular interest. A number of scientific and welfare organizations and institutions, wishing to foster and contribute to this interest, have been teaching nutritional values to popular audiences and children through records of the comparative growth of animals on good and poor diets. This comparison, when the living material is not available, is made in charts and graphs, but of course the lesson is much more impressive if the actual experimental animals of the same litter, fed on different diets, can be shown.

This method is being used by the director of nutrition research at Battle Creek Sanitarium, Michigan. Health exhibits for the public are held in the laboratories at which the experimental animals themselves are sometimes to be seen, and always interesting charts and photographs of results. A little, stunted rat who has been fed on too much sugar instead of the proper protein diet, shown beside his big, healthy brother of the same age who has had the right kind of food, is a vivid lesson to the child who is greedy for sweets. An interesting series of experiments was recently started to show the deficiencies of some of the socalled average American dietaries. Five diets were planned. Diet 1 contained meat, starches, butter substitute and sugar. Diet 2 improved on this by substituting real butter, thus giving vitamine A, previously lacking. Diet 3 had whole wheat instead of white flour, adding vitamine B and some minerals. Number 4 contained less meat, green vegetables, and malt sugar instead of cane sugar. In diet 5 all meat was omitted and milk and eggs substituted. One rat in each of the two first groups died, showing rickets. Those in the other groups lived, showing significant differences in growth and development as the diets improved. The effect of iron as a blood building food was harder to demonstrate, since the animals apparently failed to respond with any anemic conditions. It was found, however, that mother rats fed on white bread or rice and milk for several months previous to birth of a litter, although they themselves did not seem to be anemic, failed to raise healthy young, and none of the third generation on the iron free diet survived. Since the value of fruits and fresh vegetables cannot be demonstrated with rats, who seem able to thrive without vitamine

C, guineapigs are used to show the results of this lack. Guineapigs fed on oats and boiled milk, lacking vitamine C, developed scurvy, while members of the same litter given greens were entirely free from this disease.

An article in *Public Health,* published by the Michigan Department of Health, states that any of these experiments could be carried out with comparatively little difficulty in the school room or small laboratory, and the living material in this way made available for demonstration, teaching and lecturing. If possible, several experiments should be kept going at the same time, so that some demonstration is always on hand. Small, compact cages have been devised for transporting the animals from place to place. Great care should be taken that no promiscuous feeding be allowed, and that a uniform method of feeding and of cleaning the cages be maintained. The interest in animals that most children have instinctively will make the exhibits appeal to them, so that they will readily catch the significance of the living object lessons.

AUTOMOBILE FATALITIES

In a report recently issued by the industrial life insurance companies of America, covering the years 1916-1920, the section on traumatism by automobile is of especial interest as emphasizing the fact that the control of automobile accidents is today the outstanding problem of the safety movement. The death rate from this cause rose continuously throughout the five year period, the figure for the final year (12.1 in 100,000) being almost fifty per cent. higher than that for the first year (8.1). "From the viewpoint of this rising tendency," says the report, "the automobile fatality record is in contrast to those for the four other principal modes of accidental death. In the case of accidental falls, for example . . . the rate declined almost continuously from 13.6 in 100,000 in 1916 to 9.5 in 1920, there being a drop of thirty per cent. Similarly, the accidental drowning death rate fell from 9.7 in 1916 to 6.7 in 1920, or thirty per cent.; and the mortality from accidental burns declined from 8.7 in 1916 to 7.8 in 1920, which is equivalent to a decrease of ten per cent."

Another point of interest is that automobile fatalities ranked second in numerical order among the accidental causes of death, its total being slightly exceeded by traumatism by falls. The automobile fatality rate was 10.5 in 100,000 as compared with 10.8 for accidental falls. In the later years of the five covered, however, deaths from automobile accidents considerably exceeded those from falls, meaning that, from 1918 to 1920, inclusive, automobile fatalities constituted the most important cause of death in the accident group. These figures supplement those issued by the census bureau relating to the general population. "Each set of figures tells the same story of the constantly increasing death toll. . . . This is obvious, even on the basis of the mortality figures, without taking into account the nonfatal injuries, of which unfortunately there is no really full and accurate record. It is known that during the two years subsequent to the period to which this report relates the automobile accident death rate continued to increase. There must be still closer cooperation between the police, the press, the school authorities, the automobiling licensing agencies, and, above all, between automobile owners and drivers and the general public."

Automobile accidents as a cause of death now outrank most of the infectious diseases. A few years ago automobile fatalities were by no means as numerous as deaths from typhoid fever, and were outranked also by the infectious diseases of children—measles, scarlet fever, whooping cough and diphtheria. According to this report, "Deaths due to motor driven vehicles exceeded by a very considerable margin the number due to typhoid fever or to measles; their total was about double the number due to scarlet fever and to whooping cough, and about half of that caused by diphtheria. It is, perhaps, even more striking to compare the automobile accident mortality with that due to some of the leading causes of death. There is, for example, one automobile fatality to every six deaths from apoplexy; one to every seven deaths from cancer, and one to every eight deaths from Bright's disease; there is one automobile fatality to every thirteen deaths from organic heart disease, one to every thirteen deaths from pneumonia, and one to every fifteen deaths from all forms of tuberculosis combined."

The report emphasizes the realization of the fact that the published death rates do not tell the full story as to number of persons killed, and that deaths as the result of collisions between automobiles and trains or trolley cars are not classified in mortality statistics as due to motor accidents, but under the headings railroad accidents or street car accidents. A special study was made by one insurance company as to the increase that would result from adding the number of deaths from such collisions to the total from automobile accidents, and found that, in a single year, in addition to 1,642 deaths officially classified, there were sixty-five additional fatalities from collisions of automobiles with trains and forty-two from collisions with trolley cars. When these 107 deaths were added to the total for the year, the

increase in the death rate from automobile accidents was six and a half per cent.

About one half of the deaths were those of children. More than a quarter were in the age group of five to nine years. Comparatively few of these children were passengers in the automobiles. The minimum rate was reached in the age group of twenty-five to thirty-four years.

"Comparison of the death rates of the several age groups . . . brings out clearly the following facts: first, the death rate among the insured at all ages exceeds that in the general population by a margin of seventeen per cent.; second, the mortality among the children of the wage earners exceeds that of children in the general population by very large margins, namely, forty-three per cent. at ages one to four; twenty-nine per cent. at ages five to nine, and thirty-nine and one-half per cent. in the age group ten to fourteen years; third, there is also shown a much higher death rate among insured adolescents; fourth, for some reason, which we are not able to explain, the automobile accident death rate during the main working ages of life, namely, between the ages of twenty-five and fifty-five years, is lower among insured wage earners than for the general population; fifth, in old age the figures are again unfavorable to the insured."

CANNED FOODS AND PUBLIC HEALTH

Foods preserved in sealed vessels represent a large and rapidly increasing proportion of our diet, according to Dr. W. G. Savage in his recent Milroy lectures on Canned Foods in Relation to Health. The art of canning arose in response to a bounty of twelve thousand francs offered by the French government during the Napoleonic wars for a method of preserving food that would reduce waste in naval and military stores. The success of canning in our Civil War gave a further stimulus to the new industry. Since then, in war and peace, preserved foods have been employed in increasing quantities. They have the advantage over fresh milk, meat, fish, fruit, and vegetables, of being easier to transport, store, and handle. By their use, seasons or places of plenty come to the aid of hard times or districts where natural production is impossible. The bulk and variety of food at the disposal of most of us are increased, and the cost of pleasant living is lowered. And yet there is a vague dislike of the idea. Are we justified in being content with this change in diet, or is our prejudice well founded?

Dr. Savage has set forth present knowledge—much of it the result of his personal labors—on the relation of preserved foodstuffs to health. His conclusions bring comfort on the whole, but he suggests several directions in which more research is essential, as some of the existing precautions are not directed against the most serious dangers.

Preserved foods, as prepared on a commercial scale, have some initial advantage over raw goods of the shops and markets. The materials are carefully selected and carefully cleaned—for the simple reason that they "can" better. The great firms select their oxen, use quite fresh salmon, store sardines in clean water for twenty-four hours, so that their alimentary tracts may be emptied, and can their fruits and vegetables before these have lost their natural freshness. Handling is replaced almost entirely by machinery, with great gain in bacteriological cleanliness. The inspection at source by Government officials, and still more the voluntary organization of the United States packers, and at the ports of entry in England, are far in advance of the casual handling, marketing, and retailing of most of the fresh foods that reach our tables. But there are still loopholes in the control of canned goods through which much damaged or dangerous foods may reach the consumer. Some of these, as Dr. Savage shows, can be remedied by legislation, and others require more research.

Summing up his own researches and those of others, Dr. Savage has come to the rather surprising conclusion that neither the initial selection of food, the kind of treatment it undergoes before canning, nor the final "processing" or subjection of the sealed cans to heat suffices to produce absolute sterility. There are bacteria or their spores, or both, in practically every sample of canned food. When these are of the kinds which cause fermentation or putrefaction, and when the subsequent conditions are suitable for their growth, the deterioration is usually plain to the sense of sight, by alterations in the aspect of the food or distortion of the can from liberated gas, or to the sense of smell. Existing safeguards secure the destruction of a large proportion of such spoiled foods. It is doubtful, moreover, if food merely fermented or putrefied does much harm, and certainly it is not responsible for the serious cases of poisoning.

Unfortunately, the real bacterial dangers, the microbes of the Salmonella group or those which produce botulism and the toxins which they liberate, cannot be detected by the senses of smell, taste, or sight, or by their mechanical effects on the cans. Moreover, it usually happens that they are present only in one or two out of a large consignment of cans, turned out at the same time, from the same factory, and subjected to the same subsequent conditions. Still further research is required at the source, that is to say, before the preparations are marketed, to discover the mode of entrance of the dangerous bacteria and the conditions under which they escape

the effects of cooking and manufacture. The Salmonella group appears to be associated more directly with certain definite localities, as, for example, according to Dr. Savage, with South America, and the native home of the rarer bacillus of botulism seems to be the prairies rather than cultivated ground. Taken in percentages, the risk from these dangerous groups is excessively small, and least of all in the case of the products of great factories, but it does exist, and can be overcome only by specific research.

There is little to justify the common fear of danger from metallic substances in canned goods, and so far there is no basis for the popular preference for goods preserved in glass. But there is a disadvantage in diets chiefly composed of preserved foods depending on their deficiency in vitamines. The accessory substances are unstable when subjected to heat and, further, if not destroyed by the actual process of manufacture, may be still further reduced by oxidation unless the materials are soon consumed. Fat soluble A, deficiency of which is associated with rickets, is most tolerant of heat, but gives way to subsequent oxidation, so that old cans of preserved milk may be quite deficient in this respect.

SPECIAL CANCER NUMBER

The increase of morbidity from cancer and the fact that its real nature is still one of the unsolved problems of medical science makes the special cancer number of the *Canadian Practitioner* a valuable contribution to the literature of the subject. The object of the symposium is to give a brief but comprehensive discussion of the present status of scientific knowledge about cancer, especially in regard to its cause, prevention and treatment. A number of authorities on the subject have contributed valuable articles, among which are the following: The Influence of Radiation Therapy on the Study of Cancer, by Dr. James Ewing; Clinical Observations in the Treatment of Cancer of the Uterus, by Dr. A. J. Ochsner; Treatment of Hodgkin's Disease by the X Ray and Radium Based Upon a Study of 200 Cases, by Dr. W. S. Stone; Chronic Intestinal Stasis and Cancer, by Sir W. Arbuthnot Lane, Bart.; Stasis the Main Cause of Cancer, by Dr. A. C. Jordan; Carcinoma, by Sir G. Lenthal Cheatle; Prevention of Cancer of the Stomach, by Dr. Nathan Mutch; Treatment of Intraoral Cancer, by Douglas Quick, M.B.; Treatment of Carcinoma of the Antrum, by F. M. Johnson, M.B.; Radiation in the Treatment of Mammary Carcinoma, by Dr. B. J. Lee; Radium Treatment of Carcinoma of the Bladder and Prostate, by Dr. B. S. Barringer; Cancer in the Female, by Harold Chapple, M.Ch.; The Cancer Problem; Researches on the Blood in Relation to Diagnosis and Treatment, by Dr. J. A. Shaw-Mackenzie; Treatment of Cancer of the Uterus with Radium and X Ray, by Dr. W. P. Healy; Radium Treatment of Skin Cancer, by F. C. Harrison, M.B.; X Ray Examination of the Upper Abdomen for Malignant Disease, by Dr. H. M. Tovell; and What Is to Be Expected of the Radium Treatment of Cancer of the Cervix, by Dr. P. Degrais and Dr. Anselme Bellot of Paris.

In an interesting editorial by Dr. Adam H. Wright, editor of the *Practitioner,* the "positive opinion" is expressed: that the causes of cancer are to a large extent known; it can be prevented in many cases; early diagnosis has become easier and more certain; most skin cancers are curable; and a large proportion of cancers once considered hopeless can be cured.

GRADUATE MEDICAL EDUCATION IN BROOKLYN

A public health movement in which the interest of the medical profession, not only locally but throughout the country, is enlisted is the Brooklyn extension plan for graduate medical education. Although this type of medical training had long been a dream of the physicians of Long Island, it remained for Dr. Frank D. Jennings, president of the Medical Society of the County of Kings in 1922, to make the plan practicable. That year marked the centennial of this society, and it seemed to Dr. Jennings that no celebration could be more appropriate than a demonstration of public service through education of the practising physician, so he appointed a committee to develop a plan. The adoption of this plan was voted by the society, with the result that the Brooklyn Home for Consumptives, the Kingston Avenue Hospital for Contagious Diseases, the Cumberland, the Greenpoint, the Jewish, the Long Island College Hospital, the Wyckoff and the United Israel-Zion all agreed to give graduate courses under the committee's guidance. There are no clinics in the usual sense, but the teaching is clinical in that the student sees the patient. Almost all these extension courses are given in the afternoon, and are designed to meet the needs both of those physicians who are able to give several hours a week to study, and of those who have not this time. A fee is charged for the intensive courses, but the others are open. The chief subjects included in the intensive courses are tuberculosis, syphilis, focal infections, fevers, diseases of the heart, kidneys and bloodvessels, diseases of the blood, spleen, pancreas and liver, diseases of the stomach and bowel, applied anatomy and clinical laboratory work. The extension courses cover diseases of the heart, spleen, pancreas, blood and lymph glands, arteriosclerosis, diseases of the lungs, thyroid gland, lower extremity and rectum, traumatic surgery, clinical pathology, empyema, the acute abdomen, prenatal care, pediatrica, contagious diseases of infancy and childhood, urology, and obstetrical and gynecological pathology.

News Items

Harvey Lecture.—Dr. Ludwig Aschoff, professor of pathology at the University of Freiburg, Breslau, Germany, delivered the eighth Harvey Society Lecture at the New York Academy of Medicine, Saturday Evening, May 17th. his subject being Renal Secretion and Renal Disease.

Testimonial Dinner.—Dr. Robert J. Carlisle, recently appointed professor of medicine at New York University, and member of the class of 1884, was honored at a testimonial dinner given on May 3d by the Alumni Association of the University and Bellevue Hospital Medical School.

Mental Hygiene Conference.—Several Buffalo medical and social organizations held a conference on different phases of mental hygiene on May 8th, 9th and 10th.

Industrial Hygiene.—An advisory committee has been formed to draw up plans for reorganizing the Division of Industrial Hygiene of the State Department of Labor; Dr. W. Gilman Thompson, of the Reconstruction Hospital, is chairman.

Merging of Relief Societies.—The Society for the Prevention and Relief of Tuberculosis, Inc., has been merged with the New York Association for Improving the Condition of the Poor. The combined activities call for an annual budget of $260,000.

Army Medical Corps.—The Surgeon General of the Army is soliciting applications from young doctors who have had at least one year's postgraduate experience, to adopt the army medical service as a career. Examinations will commence Monday, July 28th.

National Hospital Day.—May 12th, the anniversary of the birth of Florence Nightingale, was again observed as National Hospital Day. Appropriate exercises were held at the different government hospitals, and at many other public and private hospitals.

Annual Conference of Health Officers.—The annual conference of health officers and public health nurses will be held at Saratoga Springs, N. Y., probably on June 24th, 25th and 26th. It has been suggested that the program include a special session for city health officers, under the joint auspices of the State Department of Health and the State Conference of Mayors.

Personal.—Dr. Appleton H. Pierce, Senior Surgeon, U. S. Public Health Service, Reserve, has been appointed Medical Officer in charge of the recently completed U. S. Veterans' Hospital No. 95, at Northampton, Massachusetts.

Dr. Eugene Lyman Fisk, medical director of the Life Extension Institute has sailed for th epurpose of arousing interest in the introduction of periodical health examinations.

Medical Attention to School Children.—Dr. L. W. Childs, supervisor of health education of school children in Cleveland reports that nine Cleveland hospitals have agreed to give aid to children injured in or about the schools, in case accidents happen when no school physician or nurse is present. Private practitioners cannot be called for these cases, as the school board has no authority to pay for such treatment in case the child's parents cannot pay.

Rush Medical College.—Plans have been completed for the merging of Rush Medical College and the University of Chicago. For the time being, Rush College will continue its present work. New buildings on the Midway will house the School of Medicine of the University, which on completion will absorb the work of Rush College. The new Rawson laboratories will house the postgraduate department. The units to be erected at once include the Billings Memorial Hospital, containing two hundred beds. Affiliated institutions are the Presbyterian Hospital, John McCormick Memorial Institute for Infectious Diseases, and the Home for Destitute Crippled Children. Teaching facilities are afforded by Cook County Hospital. Rush Medical College was founded about seventy-five years ago.

Activities of New York Academy of Medicine.—Of outstanding interest is the purchase by the academy of a site at Fifth Avenue and 103d Street, on which it is planned to erect buildings at a cost of $1,700,000. The property on Park Avenue has been sold.

A portrait and a marble bust of the late Dr. Arpad G. Gerster has been presented to the academy, also a portrait of Dr. Walter B. James.

A special committee of the academy has undertaken the coordination of all facilities for postgraduate medical instruction in greater New York.

Hospital Notes.—Hunts Point Hospital, in the Bronx, will be opened to the public May 11th. The superintendent will be Dr. S. B. Hirschberg, and the chief resident physician, Dr. David Miller.

The New Rochelle Hospital has increased its capacity from ninety to one hundred and fifty beds.

The Bronx Eye and Ear Infirmary, now situated on East 12d Street, has purchased ground on the Grand Concourse 166th Street, on which it will build a four story building.

The cornerstone of Hudson Towers, the hospital hotel, has been laid.

Dr. A. J. Bedell Honored.—Dr. Arthur J. Bedell of Albany has been elected chairman of the Executive Committee at the meeting of the ninety-first annual clinical congress of the New York Section of the American College of Surgeons.

To Study Industrial Diseases Abroad.—Dr. George M. Price, director of the Union Health Centre and the Joint Board of Sanitary Control, sailed for Europe on May 15th. He has been commissioned by the New York State Industrial Commissioner to study industrial diseases and their compensation.

United Hospital Fund.—The yearly distribution of the United Hospital fund has just been made, fifty-six hospitals receiving $525,000, the amount collected last year. Of this, forty-seven Manhattan hospitals received $442,000, and nine Brooklyn hospitals $82,000. In addition, over $18,000 was given to certain hospitals specified by the donors. The distribution was made on the basis of days of free treatment given by the institution, the cost of caring for ward patients, and the character of the hospital management. No distinction is made as to race or creed. Of the general hospitals, Mount Sinai received the largest amount, $41,800, but the largest single allotment went to Montefiore Hospital for Chronic Diseases, $52,500.

Smallpox.—Outbreaks of smallpox have been occurring at widely separated places. Probably the largest number have been found in Detroit, where there have been 697 cases during the first three months of 1924, and general vaccinations have been made. Forty cases of smallpox have been tabulated at New Britian, Connecticut, since the first of the year, with five deaths. Schools have been closed in Southfield, New York (a rural community near Ithaca) and in Huntington, a small town near Westfield, Massachusetts. A case of smallpox thought to have been contracted on board a ship from Bombay to Marseilles caused the death of a passenger on the *President Roosevelt*, sailing from Southampton to this country. Ninety of the first class passengers were vaccinated, and medical officers at quarantine made a close examination of all on board the ship.

League of Nations' Medical Work.—The League of Nations is working toward building up a system of international exchange of reports and epidemic diseases and statistics of their prevalence and mortality, which is felt to be especially important with regard to the countries of Asia and Eastern Europe, the locality of such severe epidemics. These studies will be handled as the Epidemicological Intelligence and Statistics Section of the League of Nations, and Dr. Otto R. Eichel of Albany, New York, has been given leave of absence from the New York State Department of Health, to direct the work. Dr. Eichel has attained unusual distinction in the scientific world for a young man, being one of the few Americans elected to Fellowship in the Royal Statistical Society of England. He has been engaged in public health work for fourteen years, and attained recognition for study of influence cycles.

Association Meetings.—The American Medical Association will hold its annual meeting in Chicago, from June 9th to 13th. Although opportunity will be given to visit the completed headquarters of the association, at 535 North Dearborn Street, said to be the largest and most completely equipped building devoted to the activities of a professional organization, the meeting itself and the exhibits will be held at the Municipal Pier.

The eighth annual meeting of the Association for the Study of Internal Secretions will be held at the Drake Hotel, Chicago, June 9th. Dr. Walter Timme, of New York, is president; Dr. T. E. Smith, first vice-president; Dr. A. T. Rasmussen, second-vice president, and Dr. F. M. Pottenger, secretary-treasurer.

The second annual meeting of the American Association for the Study of Allergy will be held at the Drake Hotel, Chicago, Monday, June 9th, under the presidency of Dr. Grant Selfridge, of San Francisco.

Other associations meeting in Chicago at practically the same time are: Medical Women's National Association, Radiological Society of North America, American Radium Society, American Society of Tropical Medicine, Associated Anesthetists of the United States and Canada, and the Medical Library Association.

MEDICAL IMPRESSIONS OF MEXICO CITY

William Sharpe, M.D.
New York

During the latter part of the summer of 1923 I had the honor of being invited by the Medical School of the University of Mexico to give a series of lectures and operative clinics in that distinguished medical centre, upon the subject of neurological surgery, and it is with much pleasure that I gratefully acknowledge the many courtesies shown to me by the members of the medical profession of Mexico City. It was my fear, at first, that on account of the heat the summer would not be an advisable season of the year for such a visit, but I was reassured that the climate was then most enjoyable and moderate and that, in fact, the months of June, July, August and September were the most pleasant ones of the entire year there. And now, after my visit, I do not hesitate to state that there is no city quite so delightfully cool during our summer time, with a climate fresh and invigorating—both as a beautiful city and as a summer resort, with its environs unequalled, an atmosphere of historic and educational interest, the charms of old Spanish architecture and historical associations—I know of no place upon the Western Continent that can compare with the capital of Mexico. The hotels are excellent in service and food, and the city is clean so that the most exacting visitor need have no fears. English is understood throughout the city and yet a speaking knowledge of the Spanish language is both interesting and helpful.

Situated in the Valley of Mexico upon a plateau having an altitude of over seven thousand feet and a diameter of almost seventy miles, surrounded on all sides by mountain ranges some of which are perennially snowcapped, a luxuriant tropical vegetation, extensive drives and promenades—to mention merely the Alameda, Avenida de la Reforma and Chapultepec Park with its beautiful lakes and trees, Mexico City has a unique charm for traveler and student alike. Some of these trees were there during the invasion of Cortez, four hundred years ago, and are now over forty feet in circumference and over two hundred feet in height. Other interesting features are the historic structures of the Plaza de la Constitucion, such as the Cathedral (almost four hundred years old and built upon the ruins of the old Aztec temple), the Palace of Cortez, the National Picture Gallery (the oldest upon the American Continent), the National Museum with its priceless treasures—the old Aztec Calendar Stone (approximately one thousand years old) and the Aztec Sacrificial Stone, upon which twenty thousand human beings were sacrificed yearly at the time of the Spanish invasion under Cortez, and numerous churches erected during the régime of Cortez and the later Spanish viceroys.

The National School of Medicine, as a department of the University of Mexico, is under the able directorship of M. Gia Gonzales, and is situated in the historic building of the Holy Office of the Inquisition, having been erected in 1732 upon the site of the first Dominican Convent built upon this continent; many of the smaller rooms were formerly used as cells for the victims of the Inquisition—the last one being the revolutionary patriot and national hero, Morelos, who was shot in 1815. The outer and inner walls are of solid masonry and over one yard in thickness, having a most unusual patio architecturally, in that the corner pillars or supports of the upper cloister are missing. The medical school is in a very flourishing condition, the number of students being even larger than before the World War, and the course is a most thorough one of six years—hospital internship and a doctor's thesis being obligatory requisites for a degree.

In a country having a culture so much older than our own in the United States, in fact, we need only to remember that at the time of the Jamestown colony in 1607 and of the Landing of the Pilgrims in 1620, the Spanish invasion of Mexico had occurred one hundred years before, and especially in this Valley of Mexico the culture and religion of Spain had become firmly superimposed upon the advanced civilization of the Aztecs, it is not surprising to find in Mexico City the oldest hospital upon the Western Continent—Hospital de Jesus Nazareno, erected in 1527 upon the site of the meeting place of Cortez and Montezuma in 1519. It is a long, low building of masonry with the ever present patio of much charm; the tropical vegetation of Mexico makes it possible to transform the commonest garden into a place of beauty with its palms and flowers the year around.

The most interesting hospital, however, from a medical point of view, is the Hospital General, covering many acres of beautiful grounds and each of its forty wards in a separate one story building and accommodating in all almost two thousand patients. The excellent window ventilation and sunlight facilities in the open patios and upon the roofed porches and promenades, the spotless cleanliness of the wards and of the patients themselves—these were most impressive and indicated an advanced degree of nursing and the proper attitude toward charity patients in hospitals; the director has reason to be proud of this institution.

The operating rooms are satisfactorily lighted and sufficiently equipped for excellent surgical work; in this regard, it is observed here as in South America, that there is an absence of surgical nurses in our meaning of the term—nurses who scrub for operations, have charge of the instruments, suture material, etc., and frequently assist in the operation itself by holding retractors, etc., and thus valuable aids if the surgical technic is to be both rapid and smooth. This development of the nursing problem in Mexico will undoubtedly come within a few years.

The x ray laboratory and equipment are most complete—the best modern apparatus having just been presented to the hospital by President Obregon. There is an elaborate Zander exercise room and also a spacious swimming pool with numerous therapeutic baths. In addition to the wards for infectious diseases, there are separate ones for typhus and also for leprosy, this latter disease being unusually common in Mexico, due to a large extent to the lack of governmental interest and control, in that patients in both the early and advanced stages of this horrible and loathsome disease are not segregated or even

mildly restricted in their daily activities, so that they may be seen not only upon the streets but in the churches and theatres, and thus greatly increasing the danger of infection. Fortunately, at present, there is an agitation in the medical profession to stimulate the Government in its duty, not only in regard to the victims themselves but also to the public and the possible future victims. On the other hand, a laudable advance has been made by the medical profession of Mexico City in regard to autopsies which are permitted upon all bodies not claimed within twenty-four hours after death in hospitals; in this manner the diagnosis may be confirmed, the real (and not merely the supposed) cause of death is ascertained, and thus the doctor acquires the proper attitude toward his work—not knowing everything, but very willing and anxious to know when a mistake is made so that future patients may benefit from this added knowledge.

The Military Hospital is another well organized institution. Until the revolution separated the Government from the Church, the two story buildings had been constructed and were being used as a convent, and throughout them may still be seen the cells into which those nuns, sinful in thought and in deed, were thrust and confined to do penance. The wards are well ventilated and clean. Outdoor sports of all kinds are now being stimulated in the army and among the youth of Mexico, so that it was not surprising to see an exciting baseball game in progress in one of the large hospital enclosures and also several soldiers receiving boxing lessons in the gymnasium—formerly the chapel!

Among the several other large hospitals of a similarly high character, such as Hospital Juarez, Hospital Beistegui, etc., there is the same constructive effort of directors, doctors and nurses to afford their patients the best possible service and it is very gratifying to record this ideal attitude. One of the most picturesque of the smaller hospitals is the American Hospital with its beautiful garden of entrance and its extensive walks among the numerous trees and tropical vegetation on all sides. Excellent work is being carried on here under Dr. Monroe, Dr. Pressley, Dr. Goodman and others, and an effort is now being made to erect a modern hospital building similar to the one now being constructed for the British Colony by a recent bequest of approximately one million dollars.

It was very impressive to observe the excellent operative technic at the different hospitals and particularly of the junior group of surgeons of forty years of age and even younger, among whom are Dr. Ortiz, Dr. Miranda, Dr. Mendizabal, Dr. Palacio Luis, Dr. Bremont, Dr. Rodillo, Dr. Ryydes, Dr. Margain, Dr. Varelas, Dr. Valverde, Dr. Meloz and others. Skilled in the most modern methods, even though their technic is handicapped by the absence of trained surgical nurses, these men are obtaining satisfactory results. Up to the present, no general surgeon has specialized or limited his work to any particular field of surgery, but apparently the time has now come in Mexico City for this further development in surgery, thus enabling the surgeon not only to extend his knowledge more and more regarding a special field, but also to perfect his operative skill and thus obtain even better results. So much more common in Mexico City than in the United States is the use of local anesthesia for appropriate conditions affecting all parts of the body and of spinal anesthesia for lower abdominal and pelvic lesions that each surgeon, thus influenced by the French school of surgery, has become an expert in its safe administration.

The medical profession, not only of Mexico City but throughout the Republic, has become more and more impressed with the need and the value of closer cooperation and thus produce an organization better adapted to the needs of the various communities and of the profession itself. Organized along lines similar to the American Medical Association, the Mexican Medical Association was formed within the past two years, having already enrolled over five hundred members. This organization will be of great benefit to the people of Mexico in that various medical suggestions regarding sanitary needs can thus be made to the Government and as the association becomes larger and more powerful, it can make a combined attack against existing unsanitary conditions and medical abuses throughout the country; in addition, medical knowledge and research work will be both stimulating and facilitated by the annual meetings.

In closing, let me repeat that I know of no more attractive and interesting city and environs to be visited by the medical profession and their families, and one more preferable as a summer resort, than the capital of Mexico. The sanitary conditions there are excellent and there need be no fear of lawless attacks—less so than in New York City. English is understood generally throughout the city, but a smattering of Spanish would be both useful and a pleasure to the visitor.

20 West Fiftieth Street.

LONDON LETTER

(From our own correspondent)

London, *April 19, 1924.*

THE ELIZABETH GARRETT ANDERSON HOSPITAL

Lord Riddell, presiding on March 11th at the annual meeting of the Elizabeth Garrett Anderson Hospital for Women in London, said that the freehold of the site on which the hospital stands had been bought as the result of the bequest to English charity of a sum of money by Mrs. Gertrude Lorillard, of New York. The number of in-patients during the past year had been 1,387 and the number of out-patients 9,964 with a total of 51,770 attendances. It was those branches of medicine that specially concerned women that had been the particular interest of medical women, and as women formed more than half the population of Great Britain this seemed only right. Mrs. Fawcett, speaking of her sister, after whom the hospital was named, said that a great deal of Elizabeth Garrett Anderson's spirit seemed to have fallen on the managing committee, which was composed equally of men and women. This equality of the sexes on the committee seemed to her so sensible and natural that she wondered why other hospitals did not adopt it. Mr. Gordon Pollock said that it was proposed to increase the in-patient accommodations, there is a waiting list of two hundred, so

as to provide for larger medical and surgical wards, a small children's ward, and adequate maternity and isolation wards. There would also be a new outpatient's department in two sections and an outpatient's theatre. It was estimated that £50,000 would be required to carry out these improvements.

FEWER DOCTORS

According to the medical correspondent of the London *Times,* a very remarkable slump has taken place in the number of entrants to the medical profession in Great Britain. In 1919 nearly 3,500 medical students were enrolled. In 1923 the number was 545. This is the lowest number for more than twenty years. The *Lancet* expresses the view that the drop is partly to be accounted for by a reduction in the number of women students. "Judging by the Christian names in the General Medical Council's list of students there are hardly more than sixty women among the total of 545 medical entrants in 1923."

ACCIDENT TO SIR ST. CLAIR THOMSON

Sir St. Clair Thomson, the well known nose and throat specialist of London, who attended the late President Roosevelt, the late King Edward and the King of the Belgians among others, was injured in the accident to the Ventimiglia express near Lyons on March 10th. It has been announced to the great relief of his many friends that his injuries are slight and that he will soon be able to resume his journey to the Riviera.

THE CANCER CAMPAIGN

The meeting of the Grand Council of the British Empire Cancer Campaign, which was held on March 7th last, was the first meeting under the amended constitution, which has been carried out in agreement with the Imperial Cancer Research Fund, the Cancer Hospital, London, the Cancer Charity of the Middlesex Hospital, and other associated bodies. Mr. S. G. Asher, chairman of the Medical School and of the Cancer and General Research Committee of the Middlesex Hospital, has become a member of the scientific advisory committee, and will serve as one of the two lay members. The committee is now complete, and consists of the following: Sir John Bland-Sutton, Dr. H. H. Dale, Sir Richard Garton, Dr. F. Gowland Hopkins, Sir William Dunn, Dr. Robert Knox, Sir William Leishman, Professor C. J. Martin, Dr. Robert Muir, Sir Humphry Rolleston, and Mr. S. G. Asher. A large number of suggested cures, treatments, and offers of services have been dealt with by a preliminary inquiry committee, under the chairmanship of Sir Charles Gordon Watson, and a certain number of these suggestions are being passed forward to the scientific advisory committee for consideration.

RESIGNATION OF DR. MARGARET BALFOUR

According to the Indian papers Dr. Margaret Balfour, head of the Women's Medical Service in India, a post she has held since 1917, has resigned, and is now on her way home. In all Dr. Balfour has given over thirty years of her life to India. In 1892 she began three years at the Women's Hospital at Ludhiana. From this place she went to Nahan to take charge of the Women's Hospital there. Her next move was to the Lady Dufferin Hospital at Patiala in 1902. In 1914 she became assistant to the Inspector General of Civil Hospitals, Punjab, which post she held until she took up the one she has just resigned. Dr. Balfour while at Delhi and Simla has been an ardent worker for various welfare schemes initiated for bettering the condition of Indian women and children. Her departure will be a great loss to India, but she is succeeded by another able practitioner, Dr. Agnes Scott, who has had over twenty years' medical experience in India.

ROYAL SOCIETY AND THE LEAGUE OF NATIONS

A special meeting of Fellows of the Royal Society of Medicine was held at the House of the Society on April 10th, to receive the medical officers of health who were visiting Great Britain at the request of the League of Nations. Some fifty medical officers of health attended, and Dr. Rajchman, Medical Director of the League of Nations Secretariat, delivered a short account of the work of the League of Nations Health Organization.

SPAHLINGER TREATMENT

In the House of Commons the other day the Minister of Health, Mr. Wheatley, in a written answer to a question said that he was anxious to arrange for a scientific investigation of the Spahlinger method of treatment in Great Britain, and had personally given Mr. Spahlinger assurances to that effect.

IMMUNIZING CHILDREN AGAINST DIPHTHERIA

The question was asked the Minister of Health in the House of Commons on March 4th whether his attention had been drawn to the remarkable results obtained by the Department of Health in New York in immunizing children against diphtheria; and whether he proposed to take steps to enable parents who desire it to obtain the advantages of this treatment for their children free of charge. The Minister of Health replied: "The answer to the first part of the question is in the affirmative. This form of preventive treatment was the subject of a special medical report by the Ministry of Health in 1921, and in July, 1922, a memorandum was issued to local authorities drawing attention to the practical advantages of the method. The question of offering the treatment to parents is for the decision of local authorities or the managing bodies of institutions, but the Ministry of Health has offered expert advice and assistance in the application of the treatment by those who desire to adopt it."

OXFORD OPHTHALMOLOGICAL CONGRESS

This congress will assemble at Reble College, Oxford, on the evening of July 2d, and the meeting will be held on the following three days. On the first morning a discussion will be held on the general principles of the treatment of convergent concomitant strabismus, with exclusion of description of details of operations to be opened by Dr. E. Landolt of Paris and Dr. Ernest Thomson of Glasgow. The Doyne Memorial Lecture will be delivered on the morning of July 4th, by Dr. T. Harrison Butler, the subject being Microscopy of the Living Eye. The official dinner of the congress will take place on the evening of July 3d.

PARIS LETTER

(From our own correspondent)

PARIS, *April 12, 1924.*

BLOOD MARRIAGE

For many decades now, Paris has attracted physicians and surgeons from Eastern Europe, for the purpose either of research or of practice. Curiously enough, not a few of them have devoted their attention to the problem of rejuvenation or, at least, of the prolongation of human life. The late Professor Metchnikoff had his hour of celebrity in this connection. As he was for many years in the research department of the Pasteur Institute, it was natural enough that his theory should have been essentially microbian. It will be remembered that he pinned his faith to lactic ferments and the suppression of raw foods. As he was little more than sixty when he died, in spite of pasteurizing his salads and ingurgitating untold quantities of curdled milk, wouldbe centenarians have deserted his doctrine. The fame of Dr. Sergius Voronoff then spread over the land. Now that the chief exponent of the glandular process is absent in Africa, rounding up chimpanzees, it is said, Dr. H. Jaworski has stepped to the front. He is the proponent of rejuvenation by the transfusion of blood, and he terms his system the "marriage of blood."

Dr. Jaworski explains that he takes small quantities of blood from a number of subjects, all young and healthy, and analyzes the samples until he finds as complete analogy as possible to the blood of the patient whom he wishes to treat. The exact sample having been found, he proceeds to transfuse a small quantity of the blood. A few drops will suffice, he asserts, because the basis of the process is qualitative and not quantitative. By this system he maintains that he has reduced arterial tension in men and women of sixty years and, in general, to have eliminated symptoms of senility. Dr. Jaworski sums up his method by declaring that such transfusion brings about "a biological rejuvenation of the organism." It should be stated, however, that his communication was made before the Paris Society of Practitioners, which is not one of the leading learned societies of France and that, apparently, he has not been averse to preliminary booming in the newspapers.

CURES DRUNKENNESS, TOO

Simultaneously comes the news from Tours, the city in the heart of the Château Country of the Loire Valley so well known to American tourists, that a local practitioner has met with much success in curing alcoholism by subcutaneous injections of the drunkard's own blood. His name is Lhospitalier and he lives at La Membrolle, in the suburbs of Tours. Dr. Lhospitalier, who has communicated to a medical journal the results of his experiments, does not seek notoriety and asks other doctors for corroboration. None the less he has applied autohemotherapy to sixteen alcoholic subjects, all of whom are now cured. He admits frankly that he stumbled upon this "booze cure" by accident. In 1919 the relatives of a prosperous farmer appealed to him to do something to kill the drink habit in him. Dr. Lhospitalier had been studying autohemotherapy from the theoretical point of view and the thought came to him that the blood of a drunkard might furnish an antidote. Taking a small quantity of the farmer's blood, he used it immediately for a subcutaneous injection. The next day the man ceased drinking; alcohol produced nausea. The effects, however, did not last longer than ten days. Consequently, the injections had to be repeated periodically, but in the intervals the patient was amenable to moral suasion and there was a complete cure. The same success was achieved in fifteen other instances. In the meantime Dr. Lhospitalier perfected his method. Instead of repeatedly taking quantities of blood, which process tends to weary the patient, he resorts to autoserotherapy, taking sixty cubic centimetres of blood and sending it to a laboratory for preparation. Then he injects half a cubic centimetre of the serum, two days later one cubic centimetre, two days later one and a half cubic centimetres, and, at intervals of two days, two cubic centimetres each time until eight injections have been made. Dr. Lhospitalier asserts that red noses become normal and also that there cannot be any question of autosuggestion in his process seeing that in several instances the patient was left in absolute ignorance of the nature and purpose of the operation.

PROGRESS OF TEMPERANCE

If one could believe statistics recently issued by the Ministry of Labor the time is within sight when Dr. Lhospitalier will find his occupation gone. This Ministry conducted an inquiry among big industrial concerns with the object of ascertaining the part which alcohol plays in the daily life of the French workman. The results are considered by the Minister to be highly satisfactory. Undoubtedly the development of athletics in this country has induced the younger generation to forsake the cafés, while the increased duty on alcoholic beverages has reduced the amount consumed by the elders, but the fact remains that the official statistics in question are not conclusive because the questionnaire was not exhaustive. Consequently Professor Letulle, of the Academy of Medicine, who actively presides over the National League Against Alcoholism, has set about to control the figures obtained by the Ministry of Labor. He is convinced that temperance has made progress but he does not wish to be too optimistic.

OYSTERS AND TYPHOID

One of the causes of alcoholism has been the rapid growth in recent years of the *vin blanc* habit. White wine is generally of greater alcoholic content than the old fashioned red wine with which the doughboy of the A. E. F. soon struck acquaintance and which played no small part in the daily ration of the poilu. Many men now take white wine in the morning instead of coffee and they have a tendency to repeat the dose throughout the day. White wine is also favored with oysters, which are very plentiful and popular in this country. Now three well known doctors have risen up against the oyster. Dr. Courtois-Suffit, Dr. Francis Bourgeois and Dr. Raymond Garcin, in a paper read before the Academy of Medicine, have given the results of observations made in 328 cases of typhoid fever. In their view, water nowadays plays a minor part in typhoid contagion. They hold that milk and especially oysters are more often responsible. The indictment against the oyster

is such that the three doctors agree in recognizing an "ostreaceous" form of the malady. The evolution is more serious and the mortality greater (seventeen per cent. against 3.6 per cent. when the contagion is due to other agents). Incidentally, it is learned that vaccination against typhoid is not proving popular, particularly in rural districts, in spite of propaganda in its favor by the Ministry of Health. Because of their 328 patients 224 were women, the aforesaid doctors argue that women do not favor antityphoidic vaccination. They seem to forget that during the war such vaccination was compulsory in the army and that the male population was mobilized between the ages of nineteen and forty-eight.

WASHINGTON LETTER

(From our own correspondent)

WASHINGTON, *April 15, 1924.*

THE RULING POWERS IN WASHINGTON

It is interesting to speculate as to just who is the Government of the United States, just who it is that really makes the wheels go round, and whose is the hand upon the rudder of the ship of state. Theoretically, the President as the head of the Executive Branch of the Government exercises this function, but manifestly he cannot know, much less direct, the multitudinous activities which are supposed to include service to 125,000,000 people. He can, it is true, outline to the members of his cabinet a general policy which he wishes pursued, much in the same manner that a millionaire yacht owner comes aboard and says, "All right, skipper, let's go to Europe." Between the outlining and the execution, however, are many steps about which he never can know, and about which he therefore can do nothing. Then, too, Congress has a habit of inserting little phrases like, "Provided, that no portion of the monies herein appropriated may be expended for ———." This is calculated to cramp the executive style, but it is as nothing to what the Director of the Budget can and does do when he feels that way—which many believe is generally. Also there's the Supreme Court. Congress proposes, but it's the Supreme Court which disposes. It used to be said that that august body was the Government of the United States, but now there are many hard pressed bureau chiefs who are muttering to themselves that the budget is the supergovernment. "Wrong!" screams the patriot. "The people guide the nation—especially election years." The people run our government exactly as does the man whose wife takes him to help her choose a hat —they pay the bills.

Who then keeps the wheels of the government oiled and in motion, who really administers our federal affairs? It's the clerks. Little musty old men, whom Dickens would have loved, wizened maiden ladies, capable encyclopedic secretaries, even the old messengers whose suavity and dignity might be a pattern for a royal court—they run the Government as inflexibly as any benevolent despotism. Cabinets may come and go, the Senate may investigate, comtrollers may make weighty decisions, reformers may breeze in from the hinterland and slink out unnoticed, but the clerks go right along as unchanging and unchangeable as the Sphinx. A new bureau chief takes his seat, filled with the holy zeal of reform and efficiency. He issues an order. His chief clerk invariably digs up an old law, executive order or comptroller's decision, which makes the contemplated action impossible. In one form or another this is repeated every time the chief tries to do something new, always kindly, even tolerantly, much as one gently thwarts a headstrong child. Struggle though he will, the chief must follow the routine established by law and precedent, and once he has learned just what to do with the dotted line he is allowed to exercise the semblance of power. This is the reason why so many strong men come into Washington full of hope, and leave it embittered by failure to achieve their ideals. It is particularly galling to professional men and scientists to be obliged to thrash over highly technical matters with Departmental Committees, Budget Committees and Appropriation Committees, and in the end find themselves hampered by the red tape on which the clerkly class feeds. So far as the medical departments are concerned, they are as much hampered as anybody else, but they manage to carry on and to do some really good work in spite of the limitations by which they are surrounded.

But government of, by and for the clerks, is not an unmixed evil. They are the stabilizers of our ship of state, and when the proletariat becomes hysterical and politicians try to rock the boat, they are the ones who keep it on an even keel. They are repositories of great stores of information, ambulatory files in which precedents are recorded. No more honest, faithful, loyal body exists in our country, and they are the force without which our government would soon cease to function and would quickly join the vanished pomps of long forgotten civilizations.

CANCER DRIVE CONCLUDED

The intensive drive against cancer conducted by the District of Columbia Committee of the American Society for Control of Cancer came to a close on April 12th, with a noon meeting in the National Theatre, and an evening lecture by Dr. James A. Cahill, Jr., which was broadcast over the radio. The noon meeting was addressed by the president of Georgetown University, Rev. Dr. John B. Creeden, the Hon. W. T. Page, and Dr. William Earl Clark. Cancer Month which began March 15th ended formally on April 15th with a public meeting at the Women's Club which was addressed by Dr. E. A. Merritt, director of the x ray laboratory at Garfield Hospital. The success of the drive has far exceeded the expectations of its proponents, and the special clinic which has been a part of the movement is now being patronized at the rate of more than two hundred patients a week. It is the belief of those who are most interested in the work that the large number of addresses which were made by the medical men of the District of Columbia and other prominent citizens will accomplish a great deal in the matter of public education, and will bring to the surgical services of the local hospital an increasingly greater number of early breast cases.

PHYSICIANS' BANQUET

The Washington Medical and Surgical Society will hold its twenty-seventh annual banquet at the Wardman Park Hotel on April 23rd. Dr. Alfred

Stengel, of Philadelphia, will be the guest of honor. Following his paper on Some General Considerations on Cardiovascular Disease which he will read at the banquet, Dr. Stengel will be made an honorary member of the society. The officers of the society are Dr. Ralph M. LeComte, president; Dr. A. C. Gray, vice-president; Dr. Albert P. Tibbets, secretary; and Dr. Frank E. Gibson, treasurer. Besides a large number of local guests, a number of distinguished medical men from nearby cities will attend the banquet which has been arranged by a committee consisting of Dr. Frank E. Gibson, Dr. Howard F. Kane and Dr. William J. Mallory.

MERCUROCHROME

The Division of Chemistry of Medical Products of the American Chemical Society has announced that mercurochrome—220 has been found valuable, not only in the treatment of ordinary infections, but has recently produced remarkable results by being injected in apparently hopeless cases of septicemia or blood poisoning. In a number of these cases the cure was exceedingly rapid. Another related compound of mercury, called flumerin, has shown promise in the treatment of syphilis." Dr. A. C. White, of Baltimore, is credited with a considerable part in this discovery.

LATIN AMERICA LETTER

(*From our own correspondent*)

BALBOA HEIGHTS, *February 15, 1924.*

MORE TREASURE HUNTERS

The average adult believes in fairies. While it would be difficult to secure from him an admission of the fact, he is sure in his heart of hearts that there is a pot of gold at the end of the rainbow. Almost every year there passes through the Panama Canal an expedition of treasure diggers led by some wily individual who is willing to profit by this frailty of humankind and usually the destination is Cocos Island which is about one hundred and twenty-five miles northwest of Puntas Arenas, Costa Rica. The exact amount of gold which is to be dug up depends upon the gullibility of the party, but always there is a time stained map which has been confided to somebody by an ancient mariner upon his death bed. Judging by the number of these maps which have appeared on the Isthmus in recent years there must be a well organized factory for their fabrication. With certain minor details, the story is always the same. About a hundred years ago, the mutinous crew of the British ship *Mary Read* buried a treasure, which had been placed on board for safe keeping during the war between Chile and Peru, on the Island of Cocos. Later the absconding crew was captured by a Peruvian punitive expedition and executed with exception of the cabin boy who was later to assume the rôle of the moribund ancient mariner. Year by year these expeditions set out and year by year they come back, always innocent of treasure except that which comes from life in the open and the adventure of strange places. The latest addition to this harmless outdoor sport is the Scientific Expeditionary Research Association of London composed of two ladies and a stewardess. A yacht has been chartered and will be met at Cocos Island, it is alleged, by the man with the map. After exhuming the treasure, which in this instance is set at £7,000,000, Easter Island, Galapagos and Malpelo will be visited for the purposes of scientific research.

PERSONALS

It is reported that Major T. J. Leary, Medical Corps, United States Army, is to be relieved as superintendent of Colon Hospital about June 1st by Major H. H. Freer, Medical Corps, United States Army. At present Major Leary is on leave status his place being filled by Major Thomas S. Mebane, Medical Corps, United States Army. Upon the completion of his duties on the Isthmus, Major Leary will take station at Fort Slocum, New York.

Among the visitors from the United States on account of the Conference of the Maritime Quarantine Authorities of the West Coast of South America were Assistant Surgeon John D. Long, United States Public Health Service, and Surgeon Samuel B. Grubbs, United States Public Health Service.

Dr. Juan Antonio Lopez del Valle, National Commissioner of Health of the Republic of Cuba, and Dr. Hugo Roberts, Chief Quarantine Officer, who attended the Conference of the Maritime Quarantine Authorities of the West Coast of South America, have returned to Havana, where they are making arrangements for the Pan-American Sanitary Congress which will convene there in November.

COMPLETION OF THE GUATEMALAN FLIGHT

On February 27, 1924, the big Martin bomber and two De Haviland planes which had made the successful flight from the France Field to Guatemala City and return alighted from their 3,000 mile journey and were received by high officials of the Army, Navy and the Republic of Panama. It is expected that the next experimental flights will be routed across Mexico to the United States thus making a trail for flyers from the Canal to Washington. While such flights have an important bearing upon aeronautics and the defense of the Panama Canal, there is a sanitary phase of the matter which must be kept in mind. As intercommunication between countries is increased in rapidity and ease, the possibility of the spread of disease is also increased and the very speed with which an infected person may thus be carried from one country to another will make their early recognition more difficult. The problem of quarantine against aircraft is one which up to date has received relatively little attention. It is true that the United States and the Panama Canal have both enacted regulations covering the quarantine of air craft but as yet they have not been put on a very practicable basis. Manifestly, the boarding of aircraft in the same way that ships are met by quarantine officers is out of the question and the distance of landing fields from quarantine stations makes the inspections of passengers and crew a difficult and time consuming operation. The real answer to the problem is for sanitarians to place their countries in such condition that they cannot spread disease and shall be noninfectible. While the quarantine problem of aircraft may seem at present to be a fanciful one, it is evident the question will soon demand solving.

Book Reviews

INTESTINAL OBSTRUCTION

The Toxemia of Acute Intestinal Obstruction. By R. H. PARAMORE, M.D., F.R.C.S. London: H. R. Lewis and Company, 1923.

Contrary to the usual views that toxemia is one of the main causes of the grave symptoms, even death, in intestinal obstruction, Paramore, while not denying the existence of some toxic products and their effect in this disease, ascribes the gravity of the situation to mechanical factors, among which he includes increased pressure in the abdominal cavity by the acts of vomiting and retching. The association of intoxication with the vomiting, the time relationship between them, seems to denote a dependence of the one upon the other and to explain the difference in these two types. In high obstruction, vomiting comes on early, and with it the exhaustion and other phenomena; in low obstruction, vomiting occurs late, and again precipitately, as it ends the fatal stage of the disease.

In intestinal obstruction, the intoxication arises with the vomiting; in cases in which the intoxication subsides, the vomiting ceases, likewise the straining and the restlessness. The effect of mechanical relief to the obstruction is the cessation of all these; the removal of the stimuli causing pain, the cessation of the violent effort in persistent vomiting, the reduction of the distention by the passage of flatus per rectum, by which the enormous increase of intraabdominal pressure falls, these are the determinant factors in the cure, and they act mechanically. The monograph of Paramore can be highly recommended.

HEMORRHOIDS

Hemorrhoids, The Etiology, Prophylaxis, and Treatment by Means of Injections. By ARTHUR S. MORLEY, F.R.C.S., Eng. Oxford Medical Publications. London: Henry Frowde and Hodder & Stoughton, 1923. Pp. 114.

Morley gives a detailed and succinct description of the etiology and treatment of hemorrhoids. The author is a warm advocate of the injection method for the treatment of internal piles, in fact, he prefers this method to surgery. Regarding his technic, Morley gives the following rules: "My own practice is to inject at each sitting all the internal hemorrhoids that are present. Sometimes this is not possible because immediately after injection, a pile swells up rapidly, and if it happens to be of over the average size, the pile first injected may swell to such an extent that it conceals some of the other smaller ones. The syringe which I find the most useful is known as Dawson's dental syringe. This is made entirely of metal, with the sole exception of a leather washer at the base of the needle socket. It can be sterilized, therefore, by boiling. The solution which I recommend and which I use in the great majority of cases, consists of a twenty per cent. solution of carbolic acid in equal parts of glycerine and water.

"The syringe being filled and all the other requisites being within easy reach, the speculum is introduced and the piles caused to prolapse into it in the manner already described. The parts are next swabbed freely with a weak antiseptic lotion, such as lysol, one dram to a pint. All traces of fecal matter are removed by swabbing, and any surplus fluid is then mopped out. The needle should be entered near the apex of each pile. The proper quantity of solution to inject into each pile is from three to eight drops, according to the size of the pile. I have found that the best interval to leave between each injection is exactly one week. It is my practice to urge that weekly injections should be continued until no trace of any of the piles can be seen. This involves an average of four injections."

The book is very practical and can be highly recommended.

GASTRIC AND DUODENAL ULCERS

Les ulcères de l'estomac et du duodenum. By ED. ENRIQUEZ and GASTON DURAND. Paris: Masson & Co., 1924.

In the last twenty years the question of gastric and duodenal ulcers has been greatly advanced by the united efforts of physicians and surgeons. Notwithstanding the great progress made in this field of medical pathology, the diagnosis of ulcers of the digestive tract and their treatment is at times very difficult. Thus, gastric hemorrhage, which is the most prominent symptom of a peptic ulcer, is not always proof positive of this affection. As is well known, splenic anemia, cirrhosis of the liver, appendicitis and other infectious states of the abdomen can be accompanied by gastric hemorrhages. The diagnosis of ulcer can be made with greater certainty when it has led to complications, principally pyloric obstruction. The x ray helps also in establishing a positive diagnosis when a Haudek niche or a constant deformity of the cap is present.

With regard to the frequency of duodenal ulcers, the authors of the present monograph agree with the American writers that this affection is very common and probably as frequent as gastric ulcer.

INFECTION OF SMALL INTESTINE IN CHILDREN

Würzburger Abhandlungen aus dem Gesamtgebiet der Medizin. Neue Folge herausgegeben von PROF. DR. E. MAGNUS-ALSLEBEN in Würzburg. Die Endogene Infection des Dünndarms beim Säugling. Klinisch-Bakteriologische Untersuchungen von DR. KURT SCHEER, Oberarzt der Universitäts-Kinderklinik mit 66 Abbildungen im Text. Leipzig: Verlag von Curt Kabitzsch, 1924.

This monograph deals with experiments on the endogenic infection of the small intestine in infancy with the aid of the duodenal tube. In healthy children, the stomach and small intestine are practically sterile, but in acute dyspepsias, especially in severe cases, and in those due to parenteral infection, the small intestine shows abundant colon bacilli. The bacterial content of the stomach in such cases varies proportionately to the existing grade of acidity. The acid resistant gram positive flora, particularly gram positive enterococci, withstand all grades of acidity and are therefore physiologically present in the healthy stomach and duodenum. The acid sensitive bacteria of the colon group are killed by pH 4:7. The flooding of the stomach with colon bacilli originates in the duodenum and is possible only when the latter is infected and when the gastric acidity is low. In that case the gastric and duodenal flora are the

same. There is no anacidity or subacidity in dyspepsia, but usually there is hyperacidity. The theory that the hydrogen ion concentration of the chyme in the upper portion of the duodenum determines the physiological sterility is advanced. With alkalinization from primary external causes, such as unsuitable food, overheating, etc., and the resulting increased excretion of alkaline intestinal juice the soil is prepared for the colon bacilli. In general the infection is confined to the chyme and bacteria do not penetrate the intact intestinal wall but only to a slight extent through areas deprived of their epithelium. These bacteria have a marked tendency toward proliferation. Agglutination tests are negative, owing to the inability of infants to produce antibodies. The clinical use of the duodenal tube is well adapted to the investigation of this endogenic infection.

HERNIA

Hernia. By Leigh F. Watson, M.D. With 232 Illustrations. St. Louis: C. V. Mosby Company, 1924. Pp. 660.

This is an excellent book on hernia, adequately illustrated with an excellent bibliography following each chapter. The author takes up first a thorough historical consideration which is interesting and well written; then the general considerations of the various types of hernia with a description of the various operations. The rarer types of hernia, both internal and external, are very well portrayed.

It is delightful to see a book of this kind, so completely up to date, with a thorough discussion, for instance, of the causes of recurrence and a review of such recent literature as Erdmann and Davis's statistics. We believe that the true analysis of such figures is advisable for every one to know. The reviewer thoroughly recommends this work.

CHRONIC AFFECTIONS

Movement in Organic Disease. By Ernest Kingscote, M.B., C.M.Edin., Hon. Physician to St. Pancras Dispensary. Late Physician-in-Ordinary to the Imperial Ottoman Embassy. New York: William Wood and Company, 1924. Pp. xix-187.

The author relates his experiences of many years n the treatment of chronic affections, especially hose of the chest, in which he endeavors to remove he cause of the disease rather than to treat the ymptoms. The subject is discussed from an entirely ew angle. The quotations on cardiac dilatation and he statistics and the dynamics of the chest, taken rom the author's *Asthma: Recent Developments in ts Treatment,* are used to support the argument pre- ented in this book. The good results obtained are ttributed to the possibility of making the fixed chest nobile, thus reestablishing the thoracic negative pres- ure, as in emphysema and allied conditions, and by he ability to reduce the dilated heart by a combina- ion of resisted movements and special breathing xercises, which are fully described. This method f treatment results in a restoration of the respira- ory movement, thereby reproducing the normal horacic negative pressure and avoiding the evil ffects of intrathoracic positive pressure.

The principles laid down also apply to the Nau- eim method of treatment. The treatment outlined s especially effective in cardiac dilatation, which has een greatly neglected by the medical profession, owing partly to inadequate means of measuring the size of the heart and partly to the want of personal touch with the methods advocated. To overcome the former obstacle, the author has devised a pleximeter with which the boundaries of deepseated organs may be delineated even when overlaid by air-containing viscera. Sufferers from fatty degeneration of the heart and angina pectoris and those who have grown old prematurely may be restored to a life of usefulness and comfort by the methods of treatment proposed. The fixed chest and the resulting cardiac dilatation, or vice versa, frequently found in chronic, socalled incurable diseases, must receive attention in the sense of restoring organs and their functions to normal. The keynote of the treatment proposed consists in the ability to change an acquired intrathoracic positive pressure into the normal negative pressure, to establish a definite ratio between the respiratory movement of the upper chest, the lower chest and the abdomen, and to reestablish the errant respiratory excursions in the various forms of fixed chest—feats that have not been accomplished heretofore. With the resulting improvement in the circulation, many chronic diseases, such as emphysema, cardiac dilatation, fatty degeneration of the heart, asthma, pulmonary phthisis, diabetes mellitus, chronic dyspepsia with gastric dilatation, myxedema and the goitres, chest deformities, nerve disorders, athlete's heart, epilepsy and obesity, are corrected. Thirty-five illustrative cases are cited.

METHODS IN MEDICINE

Methods in Medicine. The Manual in the Medical Service of George Dock, M.D., Sc.D. By George R. Herrmann, M.D., Ph.D. St. Louis: The C. V. Mosby Company, 1924.

This manual presents the system of organization which proved so successful in the medical service of Dr. George Dock at the Barnes Hospital, St. Louis. It is intended to be a practical ward or bedside guide to all those individuals who go to make up a service. The manual is divided into five parts.

Part I is made up of administrative methods, rules and detailed regulations to insure prompt, careful, complete and uniform handling of each case. These methods include a system of the duties of the resident staff from the resident physician down to the clinical clerks; notes and suggestions for history taking, physical examination and laboratory work, with the routine requirements for each type of case and the details of the ordinary clinical laboratory procedures. Part II consists of the special methods of clinical and laboratory investigation applied in a more complete study. Part III outlines acceptable therapeutic methods with emergency measures and subsequent treatment and management. Part IV contains approved dietetic methods with practical diet lists. Part V illustrates recording and graphic methods in the form of a composite history with representative charts of data from the usual types of cases.

The efficient and harmonious administration of the professional services of a hospital requires careful attention to detail, and standardization of methods. This applies not alone to administrative methods but to special methods of clinical and laboratory investigation and therapy as well. Hospital administrators and chiefs of service will find Dr. Herrmann's

book a very useful guide. It should not and cannot, of course, be employed in every institution without modification, for each hospital has its own special problems, but it should prove invaluable as a basis for organization.

One of the important educational aspects of an internship, which is too often neglected by hospital authorities, is the inculcation of careful and systematic methods, not alone in diagnosis, but in everything that concerns the relationship of the physician with the patient, the institution, and his coworkers. Along these lines this book will be very helpful. It would be well if a copy of it were placed in the hands of every resident physician.

PAUL EHRLICH

Paul Ehrlich als Mensch und Arbeiter. Erinnerungen aus dreizehn Jahren seines Lebens (1902-1915) von Martha Marquardt. Mit einer Einführung von Dr. Richard Koch, Privatdozent für Geschichte der Medizin an der Universität Frankfurt a. M. Berlin und Leipzig: Deutsche Verlags-Anstalt Stuttgart 1924. Pp. 112.

As secretary to Paul Ehrlich and as a result of close association in his work, the author was enabled to give the world glimpses of the true character of one of the greatest geniuses of modern times. This book contains numerous reminiscences and anecdotes, which reveal the characteristics, habits of thought and action, peculiarities and idiosyncrasies of Ehrlich the man at his work in his laboratory and at home. Genius has been described as an infinite capacity for work and there is no better example of genius than Ehrlich. His personal attire received but scant attention. He wasted little time on etiquette, but nevertheless he was beloved by all who came in contact with him. His simplicity was at times even childlike. He was the traditional "absent minded professor." He loved popular music, a specially heavy smoke, intensely fragrant and gayly colored flowers, a simple game of cards called patience, and he had a penchant for gayly colored pencils. His leisure reading was confined mostly to detective stories. He had a great love for animals and watched smaller animals, like insects and birds, for hours. His greatest extravagance consisted in the buying of books, all of which contained notes and markings in the margins. Borrowed books he invariably failed to return. His experimental work was planned on a card index system. His relations with his associates, assistants and employees were extremely cordial. Those in need, especially when engaged in scientific pursuits, were always supported and encouraged by advice and money, given with a free hand; he was charitable to a fault. Unfounded criticism and professional envy pained him mentally and physically. He believed in practical education, especially as it is planned in the United States. He was an indefatigable worker, as evidenced by his 606 and 914. He worked much and published little. His work he enjoyed like a child enjoys play. He deprecated the World War and believed that it should have been avoided. The numerous honors, medals and titles conferred upon him he did not enjoy as much as he cherished his honorary membership in the German Chemical Society. The man's soul is beautifully bared. Once begun, one is very reluctant to lay down the book until it has been read in its entirety.

Medicoliterary Notes.

Moses Maimonides, philosopher and physician, wrote about 1170: "Man should only believe what he can grasp with his intellectual faculties, or perceive by his senses, or what he can accept on trustworthy authority."—*Annals of Medical History.*

The Walter and Eliza Hall Institute of Research in Pathology and Medicine of Melbourne, Australia, has issued the first volume of its collected papers, covering the years 1920-1923. The volume is composed of reprints, bound together, from the *Medical Journal of Australia,* the *Journal of Pathology and Bacteriology,* the *Quarterly Journal of Medicine,* the *Lancet,* and *Una.*

* * *

The writer, Laura Kieler, nicknamed by Ibsen "the lark-bird," who was the original or Nora in *The Doll's House,* recently celebrated her seventy-fifth birthday. She lives in Northern Schleswig, and has devoted most of her life to writing in behalf of her country.

* * *

"Penguin," in the London *Observer* of February 10, writes a charming article on the subjects of umbrellas famous in literature. He feels that *the* umbrella in fiction was that of Mrs. Gamp. Others of note were Robinson Crusoe's and those mentioned or described by Dickens, Meredith, Kipling in *Kim,* Mrs. Gaskell in *Cranford,* and Miss Austen in *Mansfield Park.*

* * *

A plea for uniform standards and more practicable regulations for swimming pools is made by Arthur M. Crane, mechanical engineer, in a recent issue of the *Nation's Health.*

* * *

The recent earthquake and fire in Japan and resulting conditions are described from the point of view of a sanitarian by Dr. Kitasato of the Institute for Infectious Diseases at Tokyo, in the *Nation's Health* for February.

* * *

The *Westminster Gazette* of recent date announces the death of a curious inmate of the South Kensington Museum of Natural History. This was the grub of an unknown beetle which had lived, the paper states, for thirty years without ever undergoing the transformation into an adult. For six years this beetle had been in the care of a single keeper and with him had traveled half way around the world. Its habitat was a pencil case.

* * *

Dr. Makovitski, who was Tolstoi's physician, secretary, nurse and companion, has bequeathed in his will to the Prague National Museum a new collection of Tolstoi papers, consisting of letters, incomplete articles, and odd notes and scraps of paper, some of which bear interesting inscriptions.

* * *

It is reported that a group of industrial hygienists in and about Switzerland, most of them physicians, have arranged for an international meeting for the study of industrial hygiene problems to be held in Geneva, July 18-20, 1924.

* * *

Marcel Proust, for many years a bedridden invalid, is said to have called for his latest novel, when he felt that death was upon him, in order to correct with his own hand the passages about the demise of one of his characters, which he felt was not sufficiently true to reality. In this deathbed scene, he remarks that nature would permit only brief illnesses, which would cure themselves, but that "medicine has taken upon itself the art of prolonging them."

* * *

Dr. G. E. Harmon, of Cleveland, Ohio, has in the *American Journal of Health* for March an article, with full statistical data, on the course of mortality from puerperal septicemia for certain States of the United States from 1900-1920.

* * *

Mr. Richard Hughes has written a play especially for the radio. Faced with the apparently insuperable difficulty of necessary invisibility of his actors this ingenious dramatist hit upon the notion of placing his scene in the pitch

black blackness of a caved in coal mine. Listeners-in received the instructions to turn out the lights in their rooms in order to create the atmosphere of a coal mine . . . and were further warned that, if they thought the tragedy would be too dreadful for them, tney had better not listen in. The whole of the mining accident was sent through the air, with crashing and cursing . . . the rush of icy waters, and the final sound of the picks as the rescue party approached. The whole cast consisted of one resourceful individual plus the book of the play and a choice assortment of noise-making implements. As an English paper observes: "It seems as though a new member had been found for the club of queer trades—namely, the playwright whose chief characters are 'noises of.'"—*Living Age.*

* * *

Some interesting experiments have recently been made as to the content of sea foods. Dr. Donald K. Tessler, of the U. S. Bureau of Fisheries, has found that oysters, clams, and lobsters are rich in iodine, containing approximately 200 times as much as beefsteak or milk, while the shrimp contains about 100 times as much. These results should be of the greatest significance in regions where goitre is endemic. Mme. Randolin, chief of the French Institute of Food Hygiene, reported recently to the Academy of Science of Paris that oysters are a preventative and a quick and certain cure for scurvy. This is due to their high vitamine content.

* * *

Whether modern civilization will be saved or destroyed by science is still uncertain. Science has not only abolished the chivalry of war; it has taught the belligerents to use devices which even twenty years ago would have been thought inconceivably barbarous. And far more destructive discoveries are probable.—*Dean Inge, in London Morning Post.*

* * *

The *Clinic* is the title of a new journal of industrial surgery and hygiene, published by the Maryland Casualty Company, of Baltimore. The first number is devoted to the importance of a complete physical examination; the second emphasizes compensation features of injuries to the skeleton with joint involvement and traumatic neuroses.

* * *

Dr. Otfried Foerster, professor of psychiatry and neurology at Breslau University, who attended Lenin in his last illness, writes of this in a recent issue of the Vienna *Neue Freie Presse,* translated by the *Living Age* of April 5. Lenin's illness, says Dr. Foerster, was arteriosclerosis, probably due to an inherited tendency, for his father died relatively young of a similar arterial disease. "Undoubtedly his abnormally heavy responsibilities and duties, and the life of constant excitement he led, decidedly encouraged the development of this predisposition. . . . So insistent were the demands upon his time, as he himself told me, that for weeks and months he had scarcely two hours' sleep out of the twenty-four."

* * *

In *Public Health Reports,* for Feb. 15, 1924, Prof. James A. Duoll, of the School of Hygiene and Public Health of Johns Hopkins University, and Dr. Roy P. Sandidge, of the U. S. Public Health Service, discuss the justification of the prophylactic use of diphtheria antitoxin. The conclusion is that in young children the use of prophylactic antitoxin is clearly not only justified but demanded. In the same issue, Atherton Seidell, Ph.D., also of the U. S. Public Health Service, describes the preparation of the crystalline picrate having the antineuritic properties of vitamine B, recently so widely commented upon by the press.

Dr. William Stekel's recent work, *Peculiarities of Behavior,* has been translated into English and is published in this country by Boni & Liveright.

* * *

The secretariat of the Confederation of Italian Facisti Trades Unions has sent a communication to the U. S. Bureau of Labor Statistics stating that, with the object of uplifting the working classes socially, the confederation has decided to give its formal endorsement to a new movement called *dopolavoro* (leisure hours), which is intended to develop and effect a national program of educational recreation and instruction for the moral and physical elevation of the Italian workers. The *dopolavoro* centres, which are already functioning successfully in various provinces in connection with the Facisti trade unions, afford the workers an inducement to keep away from saloons, and to devote their spare time to such lines of recreation and sport as are recognized to be the most suited for improving their physical, intellectual, and moral state. In conformity with the above decision there has been created at the headquarters of the confederation a central bureau for the *dopolavoro* movement, with the object of organizing and developing this movement on a national scale.—*Monthly Labor Review.*

* * *

A recent issue of the *New York Medical Week* praises the valuable public service rendered by Dr. Carleton Simon, special deputy police commissioner, in charge of the narcotic division of the New York City Police Department, in his address on the narcotic problem given before a meeting of the Medical Society of the County of New York. Dr. Simon's conclusions are published in the *Medical Week.*

* * *

The followers of Ghandi in India have made an appeal to have the year of his incarceration in prison stand as the first of a new era, for which calendars are already being made and published. According to this system of reckoning time, the year one began on March 18, 1922, and ended March 17, 1923. The plea is based on the argument that the date of Ghandi's imprisonment had great religious significance, like that of the birth of Christ or that of the Hegira, and therefore marks the beginning of a new era in the history of the world.

* * *

While Ernst Toller, German playwright and revolutionist, lies in prison in one German state, his new play, *Hinkermann,* is being produced in the State Theatre in Dresden. *Hinkermann* has aroused a great storm among the conservatives and Nationalists, chiefly because Toller is an avowed Communist. There was such a riot on the first night of the play that the police had to take care of the theatre. Gas bombs were exploded and one of the audience died from fright.

* * *

Antimalaria sanatoria for children have been established in Italy in various provinces, we are told in the *World's Health.* In the most seriously affected provinces, there are thousands of pale, thin, undersized children in families who have no knowledge nor equipment with which to fight the disease through a campaign which involves ceaseless patience and perseverance. Another obstacle exists in the common belief that malaria is caused by the hand of fate. The only way to save the children is to take them away from their homes and submit them to regular and intensive medical care. The institution at Borghetto, established elsewhere in 1910, but in 1915 moved and enlarged, may be cited as one of the best of its type. It is located in a large villa, and is a veritable agricultural colony, the children doing a great part of the work, and receiving medical treatment, schooling, and proper homelife.

* * *

The transactions of the Fourth Annual Conference of Malaria Field Workers, held at Chattanooga, Tenn., in November, 1922, have recently been issued as *Public Health Bulletin* No. 137 of the U. S. Public Health Service.

* * *

The supply of crowned heads and other royalties has been so greatly depleted during the last several years that the *Almanach de Gotha,* a hundred and sixty years old, has ceased publication. This *Who's Who* of sovereigns and their families was one of the few institutions of the world to successfully defy Napoleon, whom it for years refused to recognize because he was not of noble birth. The great emperor for this reason tried to suppress its 1808 edition and threatened to confiscate its invaluable archives. This fear alone finally led to his name being included in the list of sovereigns. America was not included until the time of President Monroe, and the only American woman who was considered to have become a member of a real royal family by marriage was Alice Heine of New Orleans, whose first husband was the Duc de Richelieu and her second the Prince of Monaco.

Abstracts from Current Literature

GASTROENTEROLOGY

Investigations on the Gastric and Pancreatic Functions Following Extensive Resection of the Stomach.—Georg Stein and Egon Fried (*Wiener klinische Wochenschrift,* November 1, 1923) conclude that the extensive resection of the stomach in the vast majority of cases leads to anacidity and hypochlorhydria of the gastric juice. At the same time the ferment content of the gastric juice falls more slowly than the acidity. After about two months after the operation a more stable condition is reached, which then undergoes changes very slowly. Within the first two months the pancreatic functional test shows, as a rule, a slightly less active pancreatic juice than can be found in the fasting stomach; later on this relationship is somewhat reversed. There is no such condition as a functional pancreatic achylia or hypochlorhydria after gastric resection, but there is rather a compensatory hyperchlorhydria. The authors consider the tests carried out with the duodenal tube as useful and as a very important aid to the methods usually employed for the study of the changes occurring after resection of the stomach.

Clinical Study of Esophagospasm.—F. Lust (*Monatsschrift für Kinderheilkunde,* October, 1923) classifies esophagospasms into three main types: 1. Primary, essential esophagospasm, which is a neurosis that usually occurs in earliest infancy without any previous lesion worthy of mention. It may affect all parts of the esophageal tube including the cardia which forms a functional unit with it, in which case it is preferably called cardiospasm. A special form is the periodical esophagospasm, in which periods of patency alternate with periods of complete disturbances of food passage (esophageal crises). 2. Secondary esophagospasm, the socalled lesional esophagospasm, in which an organic change (stricture) produced by some lesion (for example, cauterization) produces the first occasion for the occurrence of spasms. A marked psychic trauma (sticking of food, severe swallowing the wrong way) may act in the same way. 3. The esophageal emotional spasms of earliest infancy, in which socalled esophageal vomiting occurs when there is marked aversion to food (for example, in the forced feeding of an undesired food, as after vegetables, pap, etc.), whereas desired foods do not give rise to any spasm.

Appendicitis, Its Infectious Cause and Its Endemic Occurrence.—A Fonio (*Schweizerische medizinische Wochenschrift,* October 11, 1923) found gram positive diplococci and bacilli in the various layers in the primary, beginning, nonsuppurative, nongangrenous or perforating appendicitis, which most probably are the cause of the appendicitis. Basing his opinion on the series of 275 cases in which an operation was done, he concludes that a contagion of the infection is frequently possible, inasmuch as fifty-five per cent. of the cases of appendicitis were definitely familial (usually in brothers and sisters) or in other persons in the immediate vicinity. This occurrence bears the character of an endemic with various periodical intervals (one to three years) in the individual cases in the household.

Bacteriophages.—R. Doerr (*Schweizerische medizinische Wochenschrift,* November 1, 1923) remarks that the d'Herelle theory of bacteriophages is recognized only by a few authors. He considers the transferable lysins (bacteriophages) as hormones for the growth of the bacteria. It is certain that they cannot be produced by the destruction of the bodies of the bacteria, as is the case with the endotoxins. The important feature of this question is not the massive destruction of the bacteria, but the vital processes which precede this terminal phase. The assumption that the transformation of the normal bacteria into formers of lysin is the result of ferments, contains a nucleus of truth. However, it is unlikely that the transferable lysins are trypsin. Experiments have shown that newly born chicks that have been raised in a sterile manner possess a potential capacity for the production of lysins even before their natural appearance and that this capacity is brought into action if germs of the typhoid colon group, in which a preexisting capacity of lysin production (contamination with bacteriophages) can be eliminated, are given by mouth. No closer relationship between autolysis and transferable bacteriolysis can as yet be designated as definitely established. However, some authors say that they have shown that certain bacteria acquire the capacity for lysis on aging, but the author was unable to observe this in cultures which could become lysinogen on contast with lysin. In order to prove the living nature of the bacteriophages, d'Herelle and others cited the results of their dilution methods, but the author was enabled to show that the initial concentration of lysin, which starts the phenomenon into action, must be the greater, the more poorly the bacterium is nourished. This does not coincide with the assumption of a living endobacterial ultramicrobe. Up to the present time the experiments are insufficient to the precise formulation of a complete theory on the nature of bacteriophages.

Relation of Gastric Ulcer to Carcinoma.—John Morley (*Lancet,* October 13, 1923) states that while one cannot deny the possibility of cancer developing in the edge of a chronic gastric ulcer, or in some part of the stomach that is or has been afflicted by a chronic gastric ulcer, his investigations provide no evidence that the development of carcinoma on gastric ulcer occurs with anything like the frequency affirmed by some authorities. The evidence set forth by the author points to the conclusion that a patient with a chronic simple ulcer of the stomach is little, if at all, more liable to develop carcinoma than a healthy individual. He finds that roughly thirty per cent. of cases of carcinoma of the stomach give rise to symptoms which simulate more or less closely those which are usually associated with simple ulcer and the author believes that it is this ulcer simulating cancer which is responsible for the belief in the cancerous degeneration of simple ulcers.

Nature and Treatment of Sprue.—H. H. Scott (*British Medical Journal,* December 15, 1923) associates the carpopedal spasms in severe cases of sprue with the carpopedal spasms of calcium deficiency together with diarrhea and intestinal toxins and parathyroid control. The treatment of this condition with calcium lactate leads only to temporary improvement, but with parathyroid extract, all the more acute symptoms disappear and the patients are cured permanently. The calcium content of the blood does not depend to any great extent upon the amount of calcium ingested, but upon the efficiency of the calcium regulating mechanism, including the parathyroid glands with their power of detoxication and regulation of the calcium metabolism. Deficiency of calcium may, therefore, be regarded as an indication of the absorption of toxins. If there is an excessive amount of fat in sprue, the calcium is excreted in excess and there is intestinal intoxication; or, there may be an excess of protein with the formation of intestinal toxins. In both conditions the detoxicating function of the parathyroids is taxed excessively, resulting in a disorganization of the calcium regulating function and a possible additional diminished absorption of calcium. Accordingly, both of these functions of the parathyroid glands are disturbed.

Carbohydrate Fermentation of Human Feces.—The fermentation test is suitable for the study of the carbohydrate fermentation of human feces and valuable in determining its basic microbial activity. E. Fricker (*Schweizerische medizinische Wochenschrift,* December 13, 1923) shows this by numerous experiments. On the addition of a one per cent. glucose solution to normal feces, marked fermentation occurred without distinct secondary fermentation. Increased peristalsis does not always lead to increased fermentation, as this depends principally upon the intestinal contents and the intestinal flora. The absence of gas formation is demonstrable in spite of the microscopical evidence of abundance of starch as a result of the lack of exciters of fermentation. The glucose test always results negatively. The effect of animal charcoal depends upon the adsorption of acids (lactate and fatty acids) and as a result there is diminution of peristalsis, improved resorption, and reduction of the conditions of life for the exciters of fermentation. There is no adsorption of gas in the fermentation test through the charcoal. Experimentally, bismuth strongly inhibits the fermentation, but a 0.1 per cent salicylic acid solution has no inhibitory action on fermentation.

Relation Between Growth Promoting and Antirachitic Functions of Certain Substances.—H. Goldblatt and S. S. Zilva (*Lancet*, September 29, 1923) conclude that the growth promoting and antirachitic properties of codliver oil are inactivated at different rates by heat in the presence of air. There is a great disparity between the growth promoting and the antirachitic potency of spinach. A certain sample of hardened codliver oil had been found to possess high growth promoting and antirachitic activity. The above observations give further support to the hypothesis of McCollum, Simmonds, Shipley and Park that the antirachitic and the fat soluble A factors are different principles.

Differential Diagnosis of Rheumatoid Arthritis as a Clinical Entity.—Vincent Coates and R. G. Gordon (*British Medical Journal*, September 29, 1923) stress the presence of achlorhydria as an etiological factor in these cases. The achlorhydria precedes not only the anemic conditions, but also chronic gastritis which has been believed to be the cause of the achylia. The gastritis is due to the failure of the normal softening and diluting action of the gastric juice, and as a result of the insufficient digestion in the stomach, the intestines are irritated and intestinal dyspepsia results. The proteins reach the intestines in an undigested state, together with bacteria, which are normally destroyed by the action of the gastric juice. The proteins, therefore, undergo still greater decomposition, resulting in the absorption of toxins.

Resection in Perforated Gastric and Duodenal Ulcer.—Anton Mülleder and Johann Neuberger (*Wiener klinische Wochenschrift*, October 18, 1923) states that in perforated gastric and duodenal ulcer the success of resection depends upon the duration of the perforation and the condition of the patient. Resection is the method of choice in every case up to twelve hours, but the authors believe that if the patient is in good condition the resection may be done successfully much later. However, individualization is necessary. Otherwise palliative operations are indicated. Resection provides the necessary security, whereas suturing leaves behind a feeling of uncertainty and the focus is left behind in the body and one can never tell whether secondary digestion may not occur. This procedure seems to be an unnecessarily severe undertaking, but together with gastroenterostomy the difference in time is not very great. In addition, the interference is very well borne. The authors are decidedly in favor of irrigating the abdominal cavity in pyloric stenosis and in gross and abundant soiling of the peritoneum with food remnants. Every form of drainage of the abdominal cavity and possibly even the subcutaneous drainage tube should be avoided. The form of anesthesia recommended is infiltration of the abdominal wall, followed by the induction of the second stage of ether anesthesia, which should be very light during the time of the intestinal suturing. For prognostic and scientific purposes it is advisable to examine the free fluid in the abdominal cavity as to its hydrochloric acid content, if possible during the course of the operation.

Congenital Diaphragmatic Hernia of the Right Side; Its Diagnosis in Life.—Philip Moen Stimson (*Archives of Pediatrics*, October, 1923) states that the usual symptoms described in cases of congenital hernia are cyanosis, rapid respiration, a sunken abdomen, an overdistended chest and dyspnea—all appearing very soon after birth. In those who survive longer, dyspnea is generally the most prominent symptom; it may be constant; it may occur in severe paroxysms, and there may be attacks of cyanosis often of great severity, owing to the accumulation of gas in the herniated hollow viscus. Vomiting is usually mentioned among the symptoms. In the author's cases of right sided hernias respiratory symptoms were noted only once in four cases, but all of them showed marked persistent vomiting, profuse and often projectile, and so repeated so frequently as to affect the nutrition profoundly.

The physical signs depend upon the size and location of the hernia and the nature of the herniating viscus. With large hernias on the left side there is usually considerable displacement of the heart to the right. The physical signs in the lungs vary considerably; there may be signs of a pneumothorax or the presence of fluid may be suggested. With a rightsided hernia there may be a layer of gastric tympany between the lung resonance and the area of liver dullness. Fluoroscopy or x ray plates clear up the diagnosis in most if not all cases. The diagnosis can often be made even without the use of barium. The line of the diaphragm may show a portion regular and a portion blurred with a gas shadow above. The hernial sac as a whole may be distinguishable as well as the fluid or gas contained therein. In questionable cases, insufficiency or eventration of the diaphragm must be borne in mind with its markedly upward and yet symmetrical displacement of an entire half of the diaphragmatic arch together with the organs situated below that half. Here, of course, there is no loss of contour of the diaphragm nor do gas shadows appear above the liver shadow. A point usually strongly in favor of the diagnosis of hernia is made when lung tissue is seen through the shadow of the gas filled stomach. Also evidences of gastrointestinal obstruction found often in hernias are not found in cases of insufficiency.

Chronic Diseases of the Colon.—E. B. Gunson (*New Zealand Medical Journal*, August 1923) thus outlines the treatment he advocates: The first consideration is to unload the bowel. The patient is put to bed. Water only is given for twenty-four hours. It is found advisable to allow a cup of tea once or twice during the day, as this affords a certain amount of stimulation and prevents uncomfortable headaches and nausea. An ordinary specimen of stool is investigated, but this affords little indication of the state of the colon. Where exhaustive laboratory tests can be made this is unquestionably the procedure of choice. As a rule, however, other and more simple means may be adopted as follows: On the second day colon lavage is commenced and applied daily until the colon has been freed of retained products. This treatment may extend over a week or ten days. In the meantime the patient is placed upon a modified diet consisting of milk or cocoa, an egg, a small quantity of meat, potato, and butter. As the colon lavage is proceeded with information is gained which throws important light upon the nature of the pathological process.

In patients who are subject to disorders of protein metabolism putrefaction of the bowel contents is present and the stool reaction is usually alkaline. Fermentation, with the evacuation of highly acid contents, indicates carbohydrate disturbance. Either of these conditions may be due simply to excess of these elements in the diet. On the other hand they may arise from inherent inability on the part of the organism to deal satisfactorily with them. Abnormal bacterial action is also a common source of trouble. Where there is active ulceration of the bowel pus may be present in quantities appreciable to the naked eye. Mucus, which is sometimes absent for long periods, and may be absent at the onset of the investigation, usually makes its appearance shortly after irrigation has been commenced. It is produced in large quantities after the removal of scybala, especially where the retention of the latter has led to erosion of the mucous membrane.

Scybalous masses, sometimes in large quantities, are removed in nearly all cases after a few days' treatment. These can be palpated very readily and their slow progress along the colon can be detected. They vary greatly in appearance. It is not unusual to find them entirely dehydrated, floating in water like pieces of cork. At times they present on their surface castlike impressions of the eroded bowel wall. In mild cases they have the appearance of being simply coated with mucus.

Bowel tissue which has been destroyed by ulceration makes its appearance. Mucous membrane appears in the form of shreds and long strings and even casts of considerable size. Muscle elements are difficult to recognize. As a result of constipation these patients frequently suffer from hemorrhoids. Apart from pain and bleeding which result from their presence, they constitute a difficulty in treatment, interfering with the passage of the colon tube; in some cases a speculum is required in order to pass the tube. After the colon has been unloaded of its retained products the general condition of the patient is greatly improved. The skin quickly regains a more normal appearance, anorexia disappears, and the patient sleeps more comfortably.

The subsequent local treatment of the bowel depends upon the presence and extent of inflammation and ulceration. Lavage is a valuable help but must be carried out with care. The two main indications for its continuance are: Persistent pain with the passage of mucus, and the retention of the bowel contents with the production of either toxic symptoms or pressure symptoms. If the liquefaction of the

bowel contents produces marked toxic symptoms from absorption, then it should be curtailed. The use of enemata in diseases of the colon is to be avoided. Intestinal antiseptics are of little value. Mineral oils are good as lubricants, but form no substitute for aperients, which must be used in many cases to insure satisfactory daily action of the bowel.

In undertaking the dietetic treatment an investigation as exhaustive as possible should be made of the stomach contents. In some cases it is found that what have been regarded as purely stomach symptoms have disappeared after the large bowel has been treated; in others, defects in gastric secretion and other stomach disturbances interfere seriously in applying the appropriate treatment to the disease of the colon. Where ulceration of the colon is present patients require a diet restricted both in quantity and in the nature of its elements. Fruit and green vegetables are not well borne, though a minimum can be tolerated. Milk is most valuable and is as a rule, easily digested. Patients who have lost much weight gain rapidly once the colon has responded to treatment, on a milk diet, a maximum of six pints in twenty-four hours, given at hourly intervals during the day, being aimed at. After the acute ulceration has subsided they do well on a diet of protein and fats with a minimum of carbohydrates. Patients suffering from cecal stasis are intolerant of protein and the diet consists of carbohydrates, fats, fruit, vegetables, with a small quantity of milk and not more than two eggs in twenty-four hours. Spastic constipation calls for regulated exercise, preferably in the open air, and a liberal allowance of vegetables and fruit.

Value of Watercress as a Food.—Harold Scurfield (*British Medical Journal,* October 27, 1923) recommends the more extensive use of watercress as a food, as it contains all of the three vitamines. It is easily cultivated and is a cheap green vegetable which need not be cooked. In addition it is available throughout the year. Its more extensive use may be of considerable assistance in correcting many dietary errors the result of city life.

Effect of Accessory Food Substances Upon the Blood.—As a result of his investigations, Kurt Jonas (*Monatsschrift für Kinderheilkunde,* September, 1923) was enabled to demonstrate that the same changes occurring in germination, which allow the antiscorbutic factors to develop, also lead to the formation of substances, which exert a marked influence upon the construction of the blood. The amount of the hemoglobin and the number of the red blood cells are increased to a marked degree as a result of the feeding of these substances in guineapigs.

GYNECOLOGY AND OBSTETRICS

Routine, Prophylactic Administration of Pituitary Extract in the Third Stage of Labor.—In comparison with the expectant, physiological method of treating the third stage of labor, A. Reist and S. Guggenheim (*Schweizerische medizinische Wochenschrift,* October 25, 1923) found that the administration of pituitary extract at the beginning of the third stage of labor gave the following results: 1. The average duration of the third stage was not shortened. The course of this stage was accelerated in a majority of cases, but it was also prolonged by the appearance of a stricture at the internal os of the cervix. 2. The average loss of blood was not measurably diminished during the third stage and an antihemorrhagic effect of the prophylactically administered pituitary extract was not observed. The number of hemorrhages and, particularly, serious and profuse hemorrhages of more than eight hundred c. c. of blood, were not only not diminished but were even increased. 3. Disturbances of the third stage occurred somewhat more frequently than with the purely expectant treatment, because the placental labor pains, induced by the injection, often appeared before the uterus reached the stage of retraction, which is necessary for the course of the physiological third stage. 4. The number of atonic secondary hemorrhages in undisturbed course of the third stage were diminished by the injections. The frequently made assertion that the pituitary medication readily leads to atony in the third stage after expulsion of the placenta, could not be confirmed in the author's material. 5. In those cases, in which disturbances in the form of hemorrhages appeared without pituitary medication in former third stages, the injections acted favorably, inasmuch as they reduced the number of the repeatedly pathological courses of the third stage to a fractional part of the cases. In such cases the prophylactic injection of pituitary extract is indicated at the beginning of the third stage. 6. There were no essential differences as regards the mechanisms of the separation and expulsion of the placenta in comparison with those occurring with expectant treatment. There was no indication for manual separation of the placenta either in the experimental or in the control cases. 7. In regard to the completeness of the membranes: In the cases treated with pituitary extract, partial retention of the placenta occurred just as often in the treated cases as in the untreated control cases. The membranes were expelled completely more often in the treated cases than in the untreated cases, but his was not observable clinically either by better involution or by a more favorable appearance of the lochia.

Vagotonia as a Symptom of Pregnancy.—On reviewing the results of his experiments, Nicolas Louros (*Zentralblatt für Gynäkologie,* October 27, 1923) arrives at the following conclusions: During pregnancy there is a disturbance in the equilibrium of the vegetative nervous system, which results in an increased sensitiveness of the parasympathetic system—vagotonia. The most prominent symptoms found by the author were: 1, reddening of the face; 2, a brunette type; 3, a positive Aschner symptom; 4, a positive Czermack symptom; 5, a positive endothelial symptom; 6, increased secretion of sweat; 7, lacrimation after an injection of adrenalin without any motive, and 8, a vagotonic adrenalin blood pressure curve. The experiments show that there is a hypersensitiveness of the parasympathetic system during pregnancy, especially in eclampsia. The few sympathicotonic curves observed indicate that sympathicotonia existed outside of the pregnancy, but this was compensated by the vagotonia of pregnancy toward the end of the pregnancy. The sympathicotonic curves of eclampsia should be interpreted in the same manner.

Taken by and large, the following conclusions may be drawn: 1. The injection of adrenalin during pregnancy produces a vagotonic blood pressure curve which gradually and usually increases toward the time of delivery, called the vagotonia of pregnancy. 2. Primary sympathicotonic phenomena are compensated during the pregnancy by this vagotonia of pregnancy. 3. Vagotonia of pregnancy is most pronounced in eclampsia. 4. It is produced by an unknown stimulation, the result of the processes of pregnancy.

Pathogenesis of Corpus Luteum Cysts.—As a result of his experiments, E. Vogt (*Zentralblatt für Gynäkologie* October 27, 1923) draws the following conclusions: The theory of the inflammatory origin of corpus luteum cysts is still unshaken. The theory of metastatic infection, however, has not been given sufficient consideration. Infection by way of the appendix does occur in isolated cases, but does not constitute the rule. Gonorrhea is usually considered only as a secondary complication. No connection between genital tuberculosis and the formation of corpus luteum cysts was observed. No definite conclusion can be drawn as yet regarding the theory of the formation of cysts in connection with dyspareunia. The theory of the development of luteum cysts as a result of the irritative effect of the cyst contents has no foundation. Clinical observations and theory do not favor the endocrine theory. The author concludes that the formation of corpus luteum cysts must be due to a sort of constitutional disease. The inflammatory irritation can be considered as the primary cause only if the prerequisites of the formation of a cyst are present, or if there are peculiar primary conditions in the corpus luteum itself or in the glandular tissue of the ovary, which in turn are of an endocrine or purely constitutional nature.

The Intravenous Use of Forty Per Cent Urotropin Solution in Gynecology.—Ernst Quack (*Zentralblatt für Gynäkologie,* December 15, 1923) does not favor the use of intravenous use of large doses (five c.c.) of urotropin as a prophylactic because of the severe vesical spasms and painful urination occasionally produced. Harmful secondary effects were not observed even in old, debilitated patients. A single intravenous injection of three c.c. of a forty per cent. urotropin solution produces a spontaneous, almost painless urination in ninety-five per cent. of cases in which there was postoperative retention of urine after twenty-four hours, and therefore, it replaces catheterization, except in a few cases. In beginning as well as in neglected cases of cystitis strikingly good therapeutic results are obtained with the intravenous use of urotropin.

Simultaneous Interruption of Pregnancy and Sterilization.—Hermann Freund (*Zentralblatt für Gynäkologie,* October 20, 1923) is in favor of the Sellheim method of interrupting pregnancy and sterilizing at one sitting. He makes the smallest possible abdominal incision, draws the uterus forward and incises the anterior surface of the body of the uterus. The ovum is loosened by blunt dissection and without rupturing it. The uterine wall is closed with interrupted sutures of silk. The sterilization of the fallopian tube is accomplished in the following manner: The tube is divided and the attached silk ligatures of the one end of the tube are used for purposes of ventrofixation of the uterus and the other end of the tube is buried in the peritoneum. In a series of seventy operations of that type the author did not encounter a single case of failure. Temporary sterilization of the tube in one case was accomplished by external fixation of the ampullæ in the abdominal wall and in another case the ampullæ were buried beneath the vaginal flaps at the time a vaginal interposition operation was also done.

Genesis of Icterus Neonatorum.—Max Turolt and Otto Tezner (*Zentralblatt für Gynäkologie,* October 20, 1923) found that the bilirubin content of the umbilical vein was greater fifteen times and diminished in the artery nine times in a series of twenty-five cases examined; the artery and vein showed equal amounts of bilirubin in one case. These differences are too great to be explained by errors. Consequently no relationship to the later developing icterus in the child could be demonstrated. The authors are inclined to believe that bilirubin is formed both in the fetus and in the placenta, but direct evidence of this could not be adduced by perfusion experiments on the surviving placenta. The placenta does not allow direct bile pigment from the mother to pass into the fetus.

Hemolyzed Autogenous Blood as a Nonspecific Stimulant.—Rob. Zimmermann (*Zentralblatt für Gynäkologie,* September 22, 1923) has injected twenty c.c. of hemolyzed autogenous blood subcutaneously or intravenously in cases of ovarian hemorrhages, and also in the hemorrhages of puberty and the climactrium, and in severely deteriorated carcinomatous cases, and has achieved good results with it. The hemolysis of the autogenous blood is accomplished by placing two c.c. of distilled water into the syringe before aspirating the blood from the vein of the arm.

Bumm's Method of Collifixation of the Uterus.—H. Keitler (*Zentralblatt für Gynäkologie,* October 20, 1923) at the present time carries out the fixation of the cervix with auxiliary operations as the method of choice in cases of extensive prolapse, especially where these is prolapse or complete prolapse or retroflexion of the uterus in women of the childbearing age, but also at a later age. The various steps in the operation are anterior colporrhaphy with reefing of the bladder, posterior colporrhaphy, suture of the levators and perineal plastic surgery. Only after all these procedures is the collifixation undertaken. The attachment is made to the fascia of the rectus muscle, together with ventrofixation of the round ligaments. In women beyond the childbearing age a broad ventrofixation of the body of the uterus is done in addition. The author believes that with this technic the best results are obtainable. With it the collifixation is reduced to a less serious procedure and it takes place alongside of the other parts of the operation as a partial operation.

Marriage, Pregnancy, Parturition, and Tuberculosis.—E. Ward (*Lancet,* September 15, 1923) finds that a tuberculous woman loses nothing by marriage alone. It is unlikely to affect her either way; if it does affect her it is more than twice as likely to improve her condition as to cause deterioration. Pregnancy and parturition are likely to make her worse; there is, however, only a fifty per cent. chance of this against a nineteen per cent. chance of improvement. But the children are seven times as likely to be tuberculous as those of healthy people. Patients who ask for advice about marriage will not take it unless it coincides with their wishes. The best way to prevent an undesirable marriage is to procrastinate. Each case must, of course, be considered on its merits from all points of view. The chief risk is to the children, and this should be emphasized. A woman of marriageable age with major tuberculosis should not bear children. To counterbalance the loss of gratification of the maternal instinct must also be placed the risks of deterioration to the patient. In regard to lactation, if milk is available it is wise for a tuberculous woman to breast-feed the child for six weeks certainly, longer in many cases, *but* never longer than eight months, and always with precautions if she is infective.

GENITOURINARY TRACT

Alkali Deficit in Nephritis.—John R. Marrack (*Lancet,* September 22, 1923) states that the most satisfactory method of detecting the presence of alkali deficit is the estimation of the bicarbonate content of the plasma, preferably together with the hydrogen ion concentration of the plasma. This gives direct information as to the actual balance of acids and bases in the blood, and indirectly in the other body fluids also. The results of plasma bicarbonate determination are usually expressed as the number of c.c. of carbon dioxide that the bicarbonate in one hundred c.c. of plasma would give off on treatment with excess of acid. The normal figures for plasma bicarbonate range between fifty-five and seventy. Cases of alkali deficit may be classified into mild with figures between thirty-five and forty-four, and severe under thirty-five.

The amount of bicarbonate given by mouth should not be more than is required to bring the plasma bicarbonate back to normal (forty). The amount required to do this can be calculated from the formula $G=W\ (40-x)\ 2$, where x is the patient's plasma bicarbonate before administration, W his weight in kilograms, and G the number of grains of sodium bicarbonate required. With this should be given $\frac{G}{20}$ grains of potassium bicarbonate, and calcium lactate. Having brought the plasma bicarbonate up to this level, the production of acid should be kept as low as possible by feeding the patient on a mainly carbohydrate diet and moderate doses of sodium bicarbonate, e. g., twenty grains three times daily.

Interstitial Cells and Seminal Epithelium.—Viktor Patzelt (*Wiener klinische Wochenschrift,* August 9, 1923) comes to the conclusion that there are important metabolic relationships between the seminal epithelium and the interstitial cells. The question as to what extent these structures are engaged in an immediate exchange of substances with each other is still undecided. At any rate, the seminal epithelium can resorb not only albuminous substances and carbohydrates necessary for its metabolism but it can also resorb lipoids directly from the adjacent bloodvessels, but nevertheless a part of these lipoids could originate in the interstitial cells. These undoubterly are engaged in an active exchange of substances, as no other theory could be assumed for the places where they are at a greater distance from the seminiferous tubules. Whether they can resorb lipoids immediately from them during the regression of the seminal epithelium, is just as questionable as the transformation of these from the interstitial cells into the seminal epithelium during the process of spermatogenesis. Both of these structures stand in a compensatory relationship toward each other as regards the body, inasmuch as the interstitial cells store up lipoids when spermiogenesis is not going on and give them off when it is going on. This compensatory activity of the interstitial cells is also of great significance to the regeneration of the seminal epithelium after an injury, and especially the storing up of the lipoids so very important for spermatogenesis. Consequently, the interstitial cells can by no means represent merely a filling tissue and they can hardly be considered as a protective arrangement for the very sensitive seminal epithelium in a functionating testicle as a result of its relatively slight development and the immediate contact between seminiferous tubules and bloodvessels, even though they, as in vital staining, can also resorb toxic substances from the blood. There are also no grounds for the assumption of a sexually specific hormone in the interstitial cells, whereas a sexually specific influence on the body is undoubtedly associated with the activity of the seminal epithelium. But when this is markedly diminished or in abeyance, then the testicle is maintained as a total organ in regard to the body as a result of the compensatory increased metabolism of the interstitial cells, even if in a diminished degree, so that signs of castration do not appear at first. The function of the interstitial cells seems to be associated with the fact that the seminal epithelium is present, even though in an indifferent state, and during puberty has achieved complete maturity at least in certain areas and has thus achieved the maturity of the body.

Medicolegal Notes.

MEDICAL EXPERT EVIDENCE IN MALPRACTICE CASES

In an action for malpractice, the Kansas Supreme Court, Saylor v. Brady, 220 Pac., 1047, held that a demurrer to the plaintiff's evidence was properly sustained because "the plaintiff offered no expert evidence to show negligence. It is the general rule in malpractice cases that the negligence in the treatment which it is claimed caused the injury must be shown by physicians or by medical witnesses called as experts."

The claim of negligence here made was that in performing a surgical operation upon plaintiff, the defendant made the incision too long and in an improper place; that he used defective catgut in sewing up the wound, and failed to use proper means to cause the wound to heal; and that he failed to give proper advice and proper treatment after the operation. "Obviously," the court said, "to entitle plaintiff to recover it was necessary for her to offer testimony by some witness who knew something of medical science, and that means a physician or surgeon, tending to show what length of incision was proper in the operation performed, where it should be made, what were the proper means to use to cause the wound to heal, or what constituted proper advice or treatment after the operation."

Plaintiff's medical witness testified that he could form no opinion upon the proper treatment in plaintiff's case without knowing the circumstances of the case, such as the nature of the operation performed by defendant upon her, the condition of the wound, and the condition of the patient. These were not stated to him in a hypothetical question, and his judgment asked thereon, nor was the negligence of the defendant shown in any way by any witness familiar with medical science.

In Pettigrew v. Lewis, 46 Kan., 78, 81, 26 Pac. 458, it was said, "Cases may arise where there is such gross negligence and want of skill in performing an operation as to dispense with the testimony of professional witnesses." If in performing a surgical operation, a metal spring twelve inches long were sewed up in the abdomen (Wharton v. Warner, 75 Wash., 470, 135 Pac. 235), or a jawbone broken in pulling a tooth was given no treatment at all (Eichholz v. Poe (Mo.), 217 S. W. 282) perhaps, the court said, medical evidence would not be necessary to show negligence, but no such situation was presented here.

The same difficulty was found as to the treatment after the operation. There was no evidence by any one competent to testify on the subject as to the period of time visits should have been continued in the condition in which plaintiff then was, nor what advice was proper to give.

The most favorable aspect in which the court could view the plaintiff's evidence was to say that some of it tended to show an unsatisfactory result. There was evidence tending to show an imperfect healing of the wound, resulting in a surgical hernia, which would perhaps necessitate a secondary operation to relieve the plaintiff; but there was no evidence that such an unsatisfactory result could have been prevented by different treatment than that given, nor that the secondary operation would have been advisable any time soon after the major operation. In addition to that, the mere showing of an unsatisfactory or poor result is not sufficient to make a physician liable in damages.

NATUROPATHS IN CALIFORNIA

Under a certificate to practise naturopathy under the California Medical Practice Act, the California courts hold, Millsap v. Alderson (Cal.), 219 Pac. 469, that one is not entitled to engage in the general practice of medicine and surgery, and that the board of medical examiners, having upon competent evidence found that he had so engaged, was justified in revoking his certificate. The materia medica of the naturopath, under the statute, are "light, air, water, clay, heat, rest, diet, herbs, electricity, massage, Swedish movements, suggestive therapeutics, chiropractic, magnetism, physical and mental culture, etc. While the naturopath is limited in his treatment to his system, the physician or surgeon is authorized to use all methods.

MALPRACTICE IN ILLINOIS AND MISSOURI

An action against a surgeon for malpractice in leaving a sponge in a patient during an operation, which was barred in Illinois, where the operation was performed, was held barred in Missouri, where the action was brought, under Missouri Rev. St. 1919, Section 1324, providing that when a cause of action has been barred by the laws of the State in which it originated, the bar should be a complete defense to any action thereon in the Missouri courts. Brown v. Grinstead (Mo. App.), 252 S. W., 973.

PROPER TREATMENT A QUESTION FOR MEDICAL EXPERTS

The relation between a physician or surgeon and his patient, implied by law, is that he possesses that reasonable degree of learning and skill ordinarily possessed by members of his profession and of his school of medicine in the community where he practises, or similar communities, having due regard for the advance in medical or surgical science at the time, and that he will use such learning and skill in the treatment of the patient with ordinary care and diligence. This general principle has been definitely settled by repeated adjudication.

In case of doubt as to which of two or more courses is to be pursued, the Kansas Supreme Court, James v. Grigsby, 220 Pac. 267, holds that he must use his best judgment. He does not guarantee good results, and no civil liability arises merely from bad results, nor if bad results are due to some cause other than his treatment; but where he fails to use ordinary care and diligence, and injury results therefrom, he is liable for the injury in a civil action for damages. These principles apply to diagnosis as well as to after treatment.

What is the proper treatment to be used in a particular case is a medical question, to be testified to by physicians as expert witnesses. Laymen, even jurors and courts, are not permitted to say what is the proper treatment for a disease, or how a specific surgical operation should be handled. Results, if so pronounced as to be apparent, may be testified to by any one. And where negligence in the treatment is shown by medical witnesses, and the evidence shows a bad result, it is the province of the jury to say whether the result was caused by the negligence.

In this case, of malpractice in setting an oblique fracture of the leg above the knee, the chief question discussed on appeal was whether the defendant, when the patient was taken to a hospital where there was an x ray machine, was obligated to take an x ray picture of the leg unless the plaintiff requested it and tendered the cost. The evidence was that it was the proper treatment to take the x ray picture if facilities were available. The court held that it was therefore the defendant's duty to take it without request, and under the evidence of both plaintiff and defendant the question of pay did not enter into it. The court doubted whether plaintiff would be required to pay in advance for the use of an x ray, any more than he would for the use of any surgical instruments or appliances or for bandages, but that did not require to be decided.

The Endocrine Treatment of Amenorrhea and Menorrhagia

GEORGE Y. OLIVER, B.A. (Cantab). M.R.C.S.
London, Eng.

During the last twenty-five years vast strides have been made in surgery but at the present time it looks as if surgery is at a standstill. At or about the same time that surgery started to develop, Brown Séquard was experimenting with orchitic extract. Now the reason why organotherapy has not made the same advances as surgery is because, in this particular branch of science, the handmaidens are biochemistry and physiology. To be able to undertake endocrinology the worker must have a full knowledge of these two sciences and as the progress of modern science goes on it is becoming almost impossible to keep these three subjects in touch with one another.

In order to approach the subject of this paper we must first of all lay down some rules for the guidance of the reader.

In the male the question of the study of organotherapy is far more simple than it is in the female, and the reason for this is as follows: In the male we are dealing with a complete unit. In the female, on the other hand, we have a mechanism so constructed that it can reproduce a facsimile of its species when an ovum is fertilized. In order that the body shall be able to produce the necessary secretions for the developing embryo it is absolutely necessary that the endocrine organs shall be able to react at once to the necessary stimuli. This is the real reason why the female endocrine glands are more unstable than the male.

To put this in another way, one can say that the endocrine glands are factories which are so arranged that all their powers of being able to manufacture goods can be mobilized at the earliest possible moment. The other point is that the glands never bear a constant ratio one to another. By this I mean, that if a child starts its life as a hypothyroid, it is quite likely that when he reaches the age of twenty-five to thirty his thyroid gland may start to work properly. Owing to the fact that the child was a hypothyroid, he will give a history of bedwetting, cord healing late, also delay in cutting his teeth and walking. As an adult he will also show signs of hypothyroidism, i. e., loss of outer third of eye brows, lower teeth crowded together, caries of teeth. Also because he is a hypothyroid the anterior pituitary will be oversecreting. This will give rise to a large sella turcica and also increased growth with overdevelopment of the gonads.

Now it is these facts which make endocrinology such a difficult and fascinating study. From the study of some hundreds of cases of endocrine derangement, the following facts have presented themselves. As the major part of the work rests on the theory of Gaskell's origin of the invertebrates, perhaps it would not be out of place to mention it briefly here.

In 1908, Walter H. Gaskell published a book entitled *The Origin of the Vertebrates*. I believe at the present moment that some zoologists decline to have anything to do with this theory. This may be right or wrong, the only thing that I can say is that the study of his book has helped me to unravel some of the problems of organotherapy. He traces the origin of vertebrates from a member of the paleostracian group and says that in the ammocetes we have evidence that the seventh nerve represents the foremost of the mesosomatic group of nerves and it supplied two segments which have united one with the other. The posterior segment which is the hyoid is a branched segment of the same character as those which are supplied by the vagus and glossopharyngeal nerves. The anterior segment forms the thyroid and differs from the rest in that instead of possessing branchiæ it carries the thyroid gland with its two ciliated grooves. From this we must assume that the branchial appendages became fused in the midlines to form a single median organ—the thyroid gland.

Now in Limulus the appendages are all fused together to form the operculum which on its posterior surface carries the genital duct one on either side. In scorpio the operculum is not free but forms part of the body wall but here also are the orifices of the genital ducts, these duct however open into a common chamber (vagina or uterus) which extends the whole breadth of the operculum and is limited to that segment alone. So much for the thyroid gland.

The anterior pituitary is developed as follows: The excretory glands of the Phyllopoda, known as the shell glands, which exist also in the Trilobite, are present in the mesostromata as the coxal gland. Now in Limulus these glands are connected to the coxæ of the 2, 3, 4, and 5 locomotor appendages. When these appendages became reduced in size and became purely tactile they were compressed and became concentrated round the mouth region, forming the en-

Copyright, 1924, by A. R. Elliott Publishing Company.

dognaths of the merostromata. As a necessary consequence of the concentration of the coxæ of the endognaths, the coxal glands also became concentrated and took up a situation close against the pharynx, when the old mouth closed and the pharynx became the saccus vasculosus and the coxal glands became the anterior pituitary, thus giving the reason why there is such a close connection between the pituitary and the infundibular region.

Whatever was the condition of the digestive tracts at the transitional stage between the arthropods and the vertebrates, the original mouth, opening at the base of the olfactory tube, was closed. The method of closure was exceedingly simple. The membrane cranium was in process of formation by the extension of the plastra laterally and dorsally, a slight growth of the same tissue in the region of the mouth would suffice to close it, and then separate the infundibulum from the olfactory tube. As evidence that such was the method of closure, it is instructive to see how in Ammocetes the glandular tissue of the pituitary body is embedded in and mixed up with the tissue of the cranial wall. Now the termination of the nasal tube which is the pars intermedia of the pituitary becomes embedded in the anterior pituitary or remnant of the coxal glands.

The posterior pituitary arises in quite another manner. In the invertebrates the brain is represented by the preoral and postoral ganglia connected by the circumoral commissure. This is the remains of the primitive brain, the rest of the central nervous system was represented by a chain of ganglia which ran the entire length of the body of the animal and then sent branches to the chromaffin system.

The other part of the central nervous system was represented by the ten cranial nerves. In this way the autonomic system arose. As soon as the need for a large brain with intellect was required, the preoral and postoral ganglia became joined together to form the posterior pituitary and it still retained its connection with the sympathetic cells by its chain of ganglia which became embedded in the spinal cord. This theory if true helps to place Sajous's idea of the posterior pituitary and its functions on a still firmer base.

Let us now recapitulate what has been said before and we find that:

I. The anterior pituitary is developed from the coxal glands.
II. The pars intermedia is the remains of the olfactory tube.
III. The posterior pituitary is the remains of the old invertebrate central nervous system linked by a chain of ganglia to the sympathetic.

These are all close to the mouth region as also are the thyroid, parathyroid, thymus and gonads, so that we see that the following glands were all closely connected to the mouth: Anterior pituitary, pars intermedia, postpituitary, thyroid, thymus, parathyroids, and gonads.

It is therefore logical to conclude that all these glands are still closely connected one with the other. I must apologize for taking up so much space with the discussion of morphology but I am of the opinion that the whole basis of organotherapy rests on these statements.

The next point to be discussed is the ovary. For some time past (1) I have divided the ovary into three parts for the purpose of treatment.

First, the ova. These are shed to my mind seven to ten days before an expected period—my proof for this is that if my theory as regards the corpus luteum is right, i. e., that it inhibits more than one ovulation taking place at a time, pain in the breasts signifies that an ovum or ova have been shed.

Second, the stroma. This controls the development of the uterus and also determines the activity of this organ as regards preparation for the ovum if it becomes fertilized. If on the other hand fertilization does not take place menstruation makes its appearance.

Third, the interstitial cells. These cells have only to do with the secondary characteristics of sex.

I now propose to take each gland separately and describe the rôle which it plays in the process of menstruation.

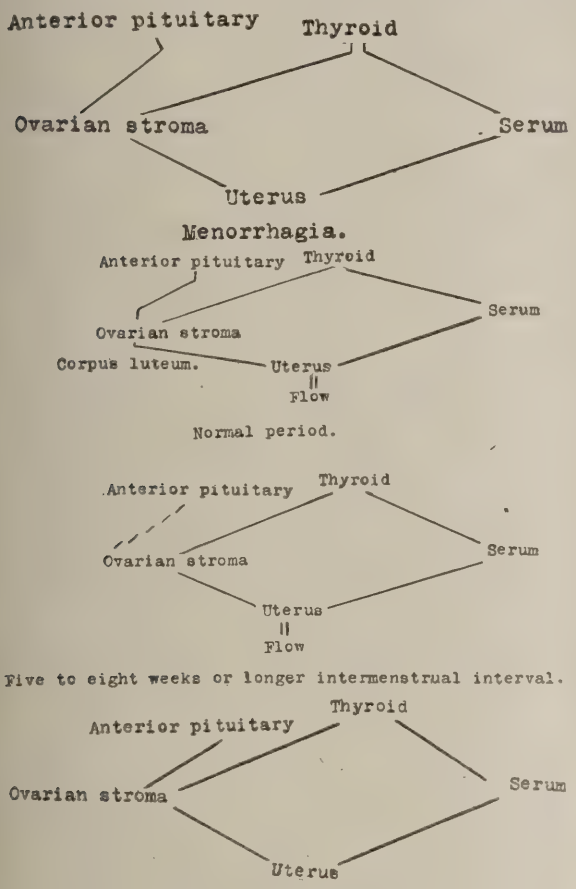
THE ANTERIOR PITUITARY

The activity of this gland is more complex than one would suppose. Personally, I believe that in the most primitive of invertebrates it was united to the thyroid gland. Some work which I have recently done seems to point to this, for if the secretion of the anterior pituitary tends to fail the thyroid gland tries to make good this deficiency; in other words, it takes on a dualistic function. In nearly all my cases of hypopituitarism of the anterior pituitary, I have found a blood pressure of 140-180 and a pulse rate of 80-120. From observations whcih I hope to publish later it would appear that this increase of pulse rate is due to the thyroid trying to make good the failing secretion of the anterior pituitary. In this type of cases, namely hypopituitarism of the anterior lobe, I have observed an increase of the basal metabolic rate and also an increase in the percentage of blood sugar which in some cases was as high as 0.15 per cent. It has also something to do with the mechanism of the skeletal muscles as all my cases had well developed muscles. This is not a deposit of fat as some observers would have us believe.

The anterior pituitary also has to do with the metabolism of sugar in the blood, lack of anterior pituitary secretion causing the percentage of blood sugar to rise. The exact opposite is found in hypothyroidism in this case the percentage of sugar may be as low as 0.07 per cent.

The anterior pituitary also determines growth as it controls the metabolism of the bones at the epiphyseal junctions. Hypopituitarism of the anterior lobe of the pituitary causes an early closure of the epiphysis and so stunted growth; hyperpituitarism of the anterior lobe causes late closure of epiphysis and thus excessive growth. It also stimulates the ovarian stroma, and so reflexly the uterus and mammæ. This is brought about in the following manner. The ovum is shed seven to ten days before the expected period. As soon as the ovum is shed the corpus luteum is formed to prevent further ovulation and at the same time the stroma causes the uterus and mammæ to be engorged with blood. The thyroid is also caused to become more active, owing to the fact that metabolism is increased. The anterior pituitary not only reinforces the thyroid secretion but it also acts on the ovarian stroma and helps in the rhythm of the periods.

For the period to start at puberty the following events must take place. The control which the thymus has over the ovarian stroma must be inhibited. The anterior pituitary together with the thyroid must be working in harmony one with the other. The following diagrams help to explain this.



AMENORRHEA OF PUBERTY

This as will be seen by the foregoing diagrams will depend on three factors. 1. Lack of ovarian stroma; 2, lack of thyroid secretion; 3, lack of anterior pituitary. Now in my opinion a person who is suffering from lack of ovarian stroma also suffers from lack of ova and also interstitial cells. This is the pure eunuchoid type. These patients are tall for their age, the legs are longer than the body, with tapering extremities, the breasts are rudimentary, pubic and axillary hairs are absent and there is lack of fat over the buttocks. I have personally seen only two patients whom one could classify into this group.

Case I.—Miss C., aged fifteen years and eight months. She was first seen in May, 1922; complained of never having had a period. She had cut her first tooth at eleven months, walked at fourteen months, had never wet the bed. (Thyroid mechanism was good.) The patient's height was five feet six inches. Hands and feet long and tapering, legs longer than the body, breasts not developed, axillary and pubic hairs absent, very thin. Blood pressure 90, pulse 74, basal metabolic rate —6. She was treated with ovarian substance (five grams) without corpus luteum. At the end of nine months her periods were regular. The response of this patient to ovarian substance is more an exception than a rule.

Case II.—This patient was aged sixteen, height six feet two inches, weight ninety-eight pounds. She was also suffering from pulmonary tuberculosis and died two months later. Ovarian substance was tried here also but as I expected, there was no result.

LACK OF THYROID SECRETION

Cases of this type are common. Lack of thyroid secretion always causes the period to appear at the age of sixteen to seventeen. Hyperthyroidism on the other hand causes the period to appear at thirteen or even earlier, provided that the other glands are working normally. Engelbach says that the hypothyroid girl menstruates at a much earlier period than the normal. The following is a typical case.

Case III.—Miss B., aged twenty-three, first seen October 3, 1921. Complained of amenorrhea since July 27, 1921, first period at fifteen; five days, twenty-eight day interval, two napkins each day. There had been no dysmenorrhea, quite regular till July, 1920. Her next period appeared November 20, 1920. It lasted five days. She used two napkins each day. July 27, 1921, seven days, one napkin only.

She was a well developed young woman. There was loss of outer third of eyebrows, lower teeth crowded together, skin dry. Mother had suffered from myxedema. The blood pressure was 120, pulse 68. The patient was given hormotone with postpituitary, one tablet t. i. d. and thyroid one quarter gram. The pulse rate rose to 74. December 25, 1921, her period lasted five days with two napkins each day. January 23, 1922, period, five days, two napkins each day. February 19, 1922, period five days, two napkins each day.

The patient was kept on hormotone and thyroid one quarter gram for another three months and up to December, 1923, has never missed a period.

I should like to remark here that I am greatly in favor of using a pluriglandular compound such as hormotone whenever it is possible as I find that they help to reinforce the action of single gland substances. The only rule that must be borne in mind with this is that thyroid substance must never be given to a patient who possesses an unstable thyroid as an unstable thyroid is one of the causes of dysmenorrhea.

LACK OF ANTERIOR PITUITARY SECRETION

These cases are likewise fairly common. The patient nearly always starts her periods late and there is also periods of amenorrhea.

Case IV.—Miss S., aged fifteen. She was first seen June 1, 1923, complained of amenorrhea. Her first period was February, 1923, five days, two napkins each day. Second period March, 1923, five days, two napkins each day. She had been slowly putting on weight. Her blood pressure was 80, pulse 72. She was given entire pituitary, one half gram t. i. d. Her period came June 14th, six days, three napkins each day, July 24th, period four days, two napkins each day. Her blood pressure was 110, pulse 72. The patient was advised to take hormotone for three months to stabilize the endocrine glands.

In order to help in the treatment of amenorrhea I have thought it advisable to insert a table of differential diagrams.

AMENORRHEA DIFFERENTIAL DIAGRAMS

	Hypoorarism	*Hypothyroid*	*Hypoanterior Pituitary*
Eyebrows	Normal	Loss of outer third	Normal
Teeth	Normal	Lower crowded together	Space between teeth
Height	Excessive	Medium	Tall
Muscles.....	Poorly developed	Flabby	Well developed
Span	Greater than height	Equal to height	Greater than height
Fat	Very thin	Plump	Plump
Breasts	Rudimentary	Normal	Normal
Hips	Large pelvis	Normal female	Normal female
First period...	Absent	Hypo, late. 16 Hyper, early. 13	Late. 16-18
Loss	Absent	Hypo, scanty Hyper, excessive	Scanty Green in color
Interval	Absent	Four weeks—months	four weeks—months
Blood Pressure.	90-110	100-120	110-130
Pulse rate.....	72-80	60-70	80-90
Blood sugar...	.09	.07-.06	.1-.14
Metabolic rate.	?	−4 to −10	−4 to −10

There is still one type of case which I would like to mention.

Case V.—Mrs. W., aged twenty-nine. First seen June 12, 1922. Complained of amenorrhea all her life. Married four years. She had three sisters all normal. She was a well developed young woman, height five feet six inches. Her weight was 132 pounds. Her teeth showed spaces between them. Her breasts were well developed, pubic and axillary hairs were present. Her blood pressure was 110, pulse 80. Both ovaries were felt and appeared normal. The uterus was very small, size one by three quarters, freely movable. Says she felt libido at times also felt discomfort each month. Her breasts felt tight. There was also pain behind the eyes. In this case we have a typical hypoanterior pituitary condition. The ovaries were normal as was the ova and also the interstitial cells as she had the secondary sex characteristics well marked. Stroma was not active owing to lack of anterior pituitary.

The patient was placed on large doses of anterior pituitary owing to its action on the stroma. Unfortunately this patient was lost sight of as she would not persevere with the treatment.

MENSTRUATION

In a paper of this description perhaps it would be best to give a detailed description of what I believe takes place.

An ovum is shed seven to ten days before the expected period. The corpus luteum is then formed to prevent other ova from being shed. The ovarian stroma then stimulates the uterus and mammæ. The uterus for descriptive purposes can be looked on as a secreting gland which nourishes the ovum. The anterior pituitary fulfills a dualistic function: It stimulates the ovarian stroma and it helps the thyroid gland with the excessive metabolism.

The increased metabolism of the uterus causes the thyroid to swell and become active.

If the ovum becomes fertilized the uterus becomes so engorged with blood that the glands of endometrium start to excrete, the cavity of the uterus becomes disturbed and at a certain point it starts to contract reflexly.

If the ovum becomes fertilized the excessive secretion of the thyroid holds the posterior pituitary in check. At full time the thyroid is unable to supply enough thyroid secretion to a, the fetus, or b, to keep the posterior pituitary in check. The posterior pituitary then stimulates all the chromaffin system and labor comes on.

The following facts are of interest. At or before an expected period the blood pressure is 100 and rises to 120. The pulse rate is 80 and rises to 88.

If the patient is pregnant the blood pressure is about 100, while the pulse rate runs up to 90 or 100. This rise of pulse rate with drop of blood pressure is always constant for pregnancy.

The same thing happens when labor comes on, blood pressure 120, pulse 80, the labor pains are strong and good.

If the blood pressure is 90 to 100 and the pulse rate is 100, labor pains are bad, the labor will be long and is usually followed by postpartum hemorrhage. In the first type of labor I always give hormotone to support all the endocrine glands. In the latter I give large doses of posterior pituitary to inhibit the thyroid secretion. This always makes the pains better and avoids postpartum hemorrhage.

MENORRHAGIA

The chief cause of this complaint from adolescence to the menopause is over active ovaries plus an irritable or over active thyroid. The treatment here is always large doses of posterior pituitary to control the thyroid, these doses must be continued until the pulse rate at the period is 80. The anterior pituitary must also be able to keep pace with the thyroid secretion. Anterior pituitary, plus; thyroid, plus; ovarian stroma, plus—menorrhagia. Anterior pituitary, normal (pain behind eyes); thyroid, plus; ovarian stroma, plus—flow normal. Anterior pituitary, minus; thyroid, normal; ovarian stroma, minus—flow scanty, green in color.

MENORRHAGIA AT THE MENOPAUSE

One has first of all to exclude cases of fibroids, polypus, carcinoma of cervix and body. Having done this there still remains a good number of cases which may be classified under one group as chronic metritis.

Fletcher Shaw (5) divides chronic metritis into three groups histologically. Chronic metritis, chronic subinvolution, hypertrophy.

Group I is found after puerperal sepsis. Group II is caused by a chronic septic condition and the result is excess of elastic and fibrous tissue throughout the uterine walls. Group III. The marked feature here is a great thickening of the endometrium. Now I am of the opinion that the most common cause of chronic metritis is a bacterial infection of the uterus. I have had a fair number of cases coming to me complaining of a discharge. Now on preparing a swab from the cervix, one always obtains a collection of bacteria like the following.

Case VI.—Miss E., aged twenty-seven. First seen June 10, 1923, leucorrhea for two years. A swab from the cervix showed staphylococci and streptococci. Vaccine were prepared from the swab and given each week. In October, 1923, the vaccine was stopped and the patient was free from all signs of a discharge even after the period.

The patients were not allowed to douche themselves while undergoing this treatmnt and were ordered hormotone to improve and tone up the general condition of the body.

The theory that I put forward at present is that the patient who has leucorrhea at the age of thirty never loses it and owing to the chronic infection which is always there the uterus at or about the

menopause becomes chronically subinvoluted and this gives rise to the hemorrhage.

Now it is a well known fact that if the child suckles the breast the uterus will involute quickly, owing to this fact I have placed all my patients on mammary tablet five gr. Six tablets each day. This was always done after I had excluded fibroids, polypus, carcinoma of cervix and body, also a high blood pressure due to hypoanterior pituitary and hyperthyroid.

On these lines my results with mammary substance have been very successful.

SUMMARY AND CONCLUSIONS

1. The study and treatment of endocrinology is easier in the male than the female.

2. The secretion of the glands may alter at or after puberty, i. e., hypothyroid may become a hyperthyroid but still retain the signs of a hypothyroid.

3. Hypothyroid child has a large sella turcica as an adult.

4. Gaskell's theory of the origin of the invertebrates discussed and its relation to the endocrine glands and the autonomic system.

5. Anterior pituitary developed from the coxal glands.

6. Pars intermedia from the olfactory tube.

7. Posterior pituitary is the remains of the preoral and postoral ganglia and still remains linked up to the chromaffin system.

8. From Gaskell's theory it is deduced that the anterior pituitary, posterior pituitary, thyroid, thymus, parathyroid and gonads are all closely related.

9. The ovary consists of three separate parts, a, the ova; b, the stroma which controls the uterus and is also acted on by the anterior pituitary; c, the interstitial cells which have to do with the secondary sex characteristics.

10. Function of anterior pituitary. a. It helps the thyroid secretion. b. Acts on the ovarian stroma. c. Is related to the storage of potassium in the muscles. d. Has to do with the percentage of sugar in the blood. e. Also with growth.

11. Diagram to show action of anterior pituitary, thyroid and ovarian stroma.

12. Causes of amenorrhea at puberty with the three types. 1. Gonads. 2. Hypoanterior pituitary. 3. Hypothyroid.

13. Treatment outlined with examples for giving ovarian, anterior pituitary and thyroid extract.

14. Table of differential diagnosis.

15. The process of menstruation described.

16. Relation of blood pressure to pulse rate at and before the period. Blood pressure 100 rises to 120, pulse 80 rises to 88. If patient becomes pregnant, blood pressure falls or remains at 100 while the pulse rate rises.

17. During pregnancy the thyroid inhibits the posterior pituitary.

18. When labor starts if the blood pressure is high and pulse low, the pains will be strong. If the blood pressure is low and the pulse rate quick the labor will be slow with a risk of postpartum hemorrhage. If posterior pituitary be given by the mouth the labor pains will improve and the pulse rate fall.

19. The chief cause of menorrhagia is an irritable or overworking thyroid. This is controlled by giving posterior pituitary. Examples of this.

20. Bleeding at the menopause, when fibroids, polypus, cancer of the cervix and body have been excluded, is caused by chronic metritis.

21. Three types of this. a, Chronic metritis; b, chronic subinvolution; c, hypertrophy.

22. Theory put forward that this is due to a bacterial infection while patient is young.

23. Treatment of leucorrhea by autogenous vaccines, with examples of cases.

24. Mammary substance advocated for menorrhagia at the menopause on the grounds that the suckling child helps the uterus to involute.

13 VENNER ROAD, SYDENHAM.

Slight Protracted Fever of Obscure Origin*

CHARLES M. MONTGOMERY, M.D.
Oteen, N. C.
Surgeon (R), U. S. P. H. S.
Chief of the Medical Service, U. S. Veterans' Hospital No. 60.

At the U. S. Veterans' Hospital No. 60, Oteen, N. C., there are or have been in the recent past at least a dozen patients out of seven hundred and fifty to eight hundred in whom a slight degree of oral fever has persisted while in the hospital lasting from several months to over a year, without any adequate explanation being found to account for it. As a result problems have arisen that are not only interesting from a scientific viewpoint but which also have a great practical significance for the patients and for the Government.

In estimating the temperatures in these cases the maximum daily temperatures covering usually one hundred or more consecutive days have been used and are reported in actual figures and percentages for various fractions of a degree of temperature.

CASE I.—This was a case of war neurosis in a typical male patient, aged twenty-eight, who was in the hospital three and one half months. Ninety-six consecutive evening temperatures showed:

37 C. (98.6 F.)	12	12.5 per cent.
37⅕ C. (99 F.)	26	27 per cent.
37⅖ C. (99.3 F.)	29	30.2 per cent.
37⅗ C. (99.7 F.)	14	14.5 per cent.
37⅘ C. (100 F.)	15	15.5 per cent.
	96	100 per cent. (approximately)

CASE II.—A typical female patient, aged twenty-five, who had been in the hospital six months. Her

*Read before the Buncombe County, N. C., Medical Society, February 19, 1923. Approved for publication by the Surgeon General, U. S. Public Health Service.

chief complaint was marked fatigability, being unwilling to walk over twenty-five minutes a day. She was subject to vertigo and a rapid pulse, was five to ten pounds underweight; refused neuropsychiatric and pelvic examinations. One hundred consecutive evening temperatures:

37 C. (98.6 F.)	1 per cent.
37⅕ C. (99 F.)	1 per cent.
37⅖ C. (99.3 F.)	28 per cent.
37⅗ C. (99.7 F.)	50 per cent.
37⅘ C. (100 F.)	18 per cent.
38 C. (100.4 F.)	2 per cent.

The majority of these temperatures were taken about 6 p. m. They had not been materially affected by meals, by rest in bed, or by ordinary walking. Malingering, which is an easy practice among the adept and with which the hospital had some experience, was excluded as nearly as possible in these cases. The thermometers had been tested, and the patients had not been restricted to a single thermometer. The time the thermometers remained in the mouth had been adequate.

The cases under consideration were rated as febrile because the patients had had an elevation of temperature exceeding the upper limits of normal temperature as given by authorities in general. According to the National Tuberculosis Association diagnostic standards: "A temperature which persistently runs over 99.4° when taken at least four times a day over a period of one week (by mouth five minutes) should be considered of significance and to constitute fever." C. L. Minor states that a persistent afternoon temperature at rest above 99.2° is very suspicious, and a temperature of 99.6° diagnostic of tuberculosis, if other things are excluded. L. Brown considers fever to be present in males with a temperature over 99°, and in females over 99.6° A. K. Krause states that under ordinary conditions of life, and in the absence of unusual mental or physical effort, few normal persons have a temperature over 98°.

It may be well to emphasize here that a given temperature elevation may have great significance in a case already established as definitely tuberculous, and the interpretation of such a temperature and its bearing on treatment may present a different problem from that of a similar temperature in a case long observed showing no demonstrable disease. The thermometer as a guide to treatment of tuberculosis and as an aid in diagnosis has different functions to perform.

In order to exclude tuberculosis in these cases full use was made of all available methods at the hospital. Careful histories and close scrutiny of the symptoms while the patients were under observation were made to determine whether the data obtainable in this way could be traced to the respiratory organs. Routine examinations were made of the chest (physical and radiological), and also routine general physical examinations. Routine examinations were also made of the sputum, urine, feces, blood (including differential counts and Wassermann tests), of the blood pressure and of the mouth (especially the teeth), the upper respiratory tract, the ears, and the eyes. If many months had elapsed it was customary to repeat all routine examinations. Besides the routine investigations advantage was frequently taken, even in the absence of any particular indications, of special examinations, for example by the surgeon to eliminate any surgical, genitourinary, rectal or other condition, or of a neuropsychiatric examination by a specialist in this line, or of special gastroenterological studies, and also of basal metabolism and other tests. A very helpful feature in the investigation of these cases was the protracted period during which observation and study were carried on while the patients were in the hospital. Unfortunately most of the female patients refused pelvic examinations, and it is of interest that the proportion of these patients with inexplicable fever far exceeded that of the male patients.

Regarding the chest examinations of this group only those cases are included which were pronounced negative by two or more experienced clinicians, usually on more than one examination, and which were reported as negative or doubtful by one or more experienced radiologists, who usually had the advantage of comparative readings.

The manifestations in this group did not cover a wide range. Most of the patients complained of feeling poorly or sick and were manifestly not well. Failure to improve with continued hospital treatment was striking in several instances. Symptoms were not traceable directly to the lungs or pleura, although some of the patients had chest pains and were subject to dyspnea on slight provocation. The chief complaint in most of the cases, and the commonest complaint, was fatigability in some form. This symptom was especially marked in the female patients. A rapid or excitable pulse was common, and also some degree of nervousness. The weight was frequently slightly subnormal, even with hospital care. General pains occurred in some of the cases but were not a prominent feature. Distinct feverishness was complained of in one case. The mental manifestations revealed no distinct psychosis, but several patients had peculiar mental attitudes, partly the result of prolonged hospitalization, of compensation problems or war neuroses. Gastrointestinal symptoms played a minor rôle.

The problem of diagnosing these fever cases that give no manifestations of any definite disease is similar to that involved in any indefinite cases whether fever be present or not. In other words, the problem is concerned with the broad problem of diagnosing incipient or minimal disease in general. In attempting to determine the cause of such obscure fever four lines of investigation will be pursued. First, is the fever due to some cryptic infection other than tuberculosis? Secondly, is it due to tuberculosis of the socalled occult type? Thirdly, is it due to some disease other than infectious? Fourthly, is it possible that any of these patients are exhibiting what is for them a normal oral temperature?

Every effort, as has been stated, has been made to exclude cryptic infections. It is realized that such infections may produce no symptoms, or that such symptoms as are produced may be of a general toxic nature, and that if they cause local symptoms these symptoms may be distant from the focus of infection. The indications are clear then to search all available areas for possible sources of hidden infec-

tion. Even then the implicated area may be beyond our reach.

While giving all due consideration to cryptic focal infections as a possible source of fever of prolonged duration, it is interesting how little evidence there is that such foci frequently maintain a daily elevation of temperature for months or years in the absence of distinct localizing symptoms, for example, from an arthritis, or in the absence of acute exacerbations. In the many excellent articles dealing with focal infections the temperature receives scant treatment in comparison with other symptoms. In the average case with chronically infected tonsils or teeth or other tissues and with protracted constitutional symptoms, clinical records are ordinarily lacking that would show a daily temperature record properly taken with the thermometer left in the mouth for five or ten minutes, this record being maintained for months or years, and exhibiting a distinct febrile elevation. There is a general impression that many focal infections are fever free except during acute exacerbations. In the cases at Oteen in which a manifest source of focal infection was demonstrated and removed, the temperature had not regularly returned to normal.

Gastrointestinal examinations, especially with the x ray, were the rule in these cases, regardless of any special indications, because of the large area liable to cryptic infection. One patient, who had been in the hospital for some time with no condition found except chronic appendicitis, had had constantly a slight fairly uniform fever comparable to that described in the present group of cases. Another patient, with the only condition found a gastroenteroptosis of moderate degree, had been subject to a similar fever for about one year. Old chronic prostatic infections were found in cases otherwise negative, some with, some without fever. Occasionally a patient was treated for diagnostic purposes with antiluetic treatment in the absence of a positive Wassermann, and with prolonged quinine administration in the absence of positive blood findings, in both instances without noticeable results. There was no eosinophilia to suggest trichinosis.

A second source of fever in these obscure cases that suggests itself is a hidden or occult tuberculosis in the chest or elsewhere, yielding no definite manifestation. Can these cases represent a period in the development of tuberculosis between the time of infection and manifest disease? If we are really dealing with such a condition, it is a rare opportunity that we naturally want to make the best of, to the patient's great and lasting good. On the other hand, unnecessary hospitalization is harmful to the patient and wasteful of money. Why should such a stage of tuberculosis last one year or more, all the time yielding an elevation of temperature that resists even complete bed rest and shows no increase on free exercise? Unless, indeed, we assume that such a closed and cryptic stage yields more systemic intoxication than the open lesions with free external drainage. Certain it is that in most of the minimal and moderately advanced cases seen fairly early in the disease, and even in many far advanced cases, a few weeks or months in bed will reduce the temperature to normal, a result not obtained in the group under immediate consideration. H. Sewall actually considers that the temperature in occult tuberculosis offers a distinct contrast to that of incipient pulmonary tuberculosis, the former commonly exhibiting no febrile rise, while the latter usually shows an afternoon elevation of temperature. An investigation of fever in nonpulmonary tuberculosis, for example in the glands or bones, many times yields barren results, as the temperature has not been taken often enough or with sufficient care. Available records indicate, however, that nonpulmonary tuberculosis can be quite active and yet reveal no fever, or that the fever will subside rapidly on complete rest, exhibiting a marked contrast to the cases of obscure fever under discussion.

The third group containing abnormal conditions that may suggest themselves as possible sources of constant slight fever deals with those cases which are not due to focal infections or chronic inflammatory affections of any type. Various nervous and psychical conditions are interesting in this connection. Some neuropsychiatric specialists give us little encouragement along these lines, others think nervous conditions may be able to occasion fever of the type described. Unfortunately most of us are unfamiliar with any satisfactory series of temperature records in neuropsychiatric cases that might illumine the subject. Theoretically, it seems possible for nervous influences to affect the temperature either directly by acting on the thermogenic centres, or indirectly, by interfering with metabolism and by producing conditions favorable for bacterial activity, for example in the gastrointestinal tract. Endocrine disturbances suggest themselves as capable of playing some part in febrile reactions. Toxic goitre cases are at times associated with fever.

It appears reasonable to believe that whatever the immediate cause of a fever may be, even if infectious in nature, the primary cause may be entirely free from any infectious factor.

The fourth possibility, that some of these cases may have a temperature which for them is entirely normal, remains neither proved nor disproved. It might be assumed that in some individuals, because of the local blood supply in the mouth, or for some other local reason, the temperature registers higher in them than in most persons. Such a thought receives some support in those cases in which the rectal temperature more closely approximates the normal than does the oral. One might hazard a guess that some human beings have less stable thermogenic centres, so that they register more delicately slight toxic and other influences not detected in the majority of cases. The safest policy on our part as far as the febrile individual is concerned, is to admit our ignorance of the cause of such fever, so that efforts to unravel the etiology will not be abated.

The answer to the practical question as to the disposition of cases with prolonged slight fever of undetermined origin will vary somewhat with the types of cases. All of these persons should be kept under some sort of observation though by no means should all be indefinitely hospitalized. All will do well to profit by at least a limited period of hospitalization or its equivalent, in order to watch more

closely the temperature and to help in diagnosing the case. Those appearing in good health and reacting well to exercise can relatively soon be discharged from the hospital. Those who are manifestly in poor health should ordinarily be discharged from a tuberculosis hospital after a few months of close study, hospitalization in a different type of institution being sometimes indicated.

TYPICAL CASES OF OBSCURE FEVER

Other typical cases exhibiting obscure protracted fever are as follows:

Case III.—Male, aged thirty, admitted June 1, 1922, discharged January 1, 1923. The patient presented slight but distinct finger clubbing extending back of nails. On admission, he was feverish, sweating, very tired and weak, but fairly well on discharge. One hundred and forty-seven evening temperatures prior to discharge:

Below	37	C. (98.6 F.)	1	
	37	C. (98.6 F.)	15	10 per cent.
	37⅕	C. (99 F.)	68	46 per cent.
	37⅖	C. (99.3 F.)	48	33 per cent.
	37⅗	C. (99.7 F.)	15	10 per cent.
			147	100 per cent. (approximately)

Case IV.—Male, aged twenty-eight, admitted October 5, 1922, discharged December 31, 1922. Chief complaint was compensation difficulties. Seventy-eight consecutive evening temperatures:

Below	37	C. (98.6 F.)	4	5 per cent.
	37	C. (98.6 F.)	7	8.7 per cent.
	37⅕	C. (99 F.)	19	24.4 per cent.
	37⅖	C. (99.3 F.)	30	38.5 per cent.
	37⅗	C. (99.7 F.)	13	16.7 per cent.
	37⅘	C. (100 F.)	5	6.4 per cent.
			78	100 per cent. (approximately)

Case V.—Male, aged twenty-six, admitted August 9, 1921, discharged January 30, 1923. The patient was suffering from war neurosis, was averse to leaving the hospital, presented marked clubbing of fingers extending back of nails. Fever was present last half of stay in hospital. He was twenty pounds underweight; walked three miles a day. One hundred evening temperatures prior to discharge:

Below	37	C. (98.6 F.)	5 per cent.
	37	C. (98.6 F.)	21 per cent.
	37⅕	C. (99 F.)	35 per cent.
	37⅖	C. (99.3 F.)	27 per cent.
	37⅗	C. (99.7 F.)	10 per cent.
	37⅘	C. (100 F.)	1 per cent.
	38	C. (100.4 F.)	1 per cent.

Case VII.—Female, aged thirty-four, admitted January 27, 1922, still in hospital February 15, 1923 (discharge recommended). Her chief complaint was fatigability, would walk only twenty-five minutes a day; eight pounds underweight; tonsillectomy with no appreciable effect. One hundred consecutive evening temperatures:

Below	37	C. (98.6 F.)	6 per cent.
	37	C. (98.6 F.)	4 per cent.
	37⅕	C. (99 F.)	3 per cent.
	37⅖	C. (99.3 F.)	14 per cent.
	37⅗	C. (99.7 F.)	32 per cent.
	37⅘	C. (100.04 F.)	30 per cent.
	38	C. (100.4 F.)	11 per cent.

In addition to the type of cases forming the basis of this paper there have been a number of others at Oteen exhibiting a comparable type of fever, diagnosed also as nontuberculous, but with some condition that for obvious reasons excluded them from the group in question.

Case VIII.—Male, aged twenty-seven, admitted August 18, 1921, discharged about February 16, 1923. Diagnosis: Psychoneurosis, neurasthenia, mild type, perforated nasal septum, malingerer. Chief complaints were fatigability and chest and shoulder pains. One hundred consecutive evening temperatures:

37	C. (98.6 F.)	9 per cent.
37⅕	C. (99 F.)	29 per cent.
37⅖	C. (99.3 F.)	37 per cent.
37⅗	C. (99.7 F.)	17 per cent.
37⅘	C. (100 F.)	8 per cent.
38	C. (100.4 F.)	0 per cent.

Case IX.—Female, aged thirty-nine, in the hospital eight months. High blood pressure (systolic usually 170), gastroenteroptosis, subnormal weight, chief complaint marked fatigability, also quite nervous. One hundred consecutive evening temperatures:

Below	37	C. (98.6	F.)	1 per cent.
	37	C. (98.6	F.)	1 per cent.
	37⅕	C. (99	F.)	1 per cent.
	37⅖	C. (99.3	F.)	16 per cent.
	37⅗	C. (99.7	F.)	52 per cent.
	37⅘	C. (100.04	F.)	23 per cent.
	38	C. (100.4	F.)	6 per cent.

Case X.—Male, aged twenty-three, admitted December 9, 1920, discharged February 3, 1923. Fever chiefly since contracting gonorrhea one year ago. Diagnosis: Chronic gonorrheal prostatitis, perforated nasal septum. Patient was very averse to being discharged. One hundred consecutive evening temperatures:

Below	37	C. (98.6 F.)	4 per cent.
	37	C. (98.6 F.)	16 per cent.
	37⅕	C. (99 F.)	38 per cent.
	37⅖	C. ((99.3 F.)	25 per cent.
	37⅗	C. (99.7 F.)	12 per cent.
	37⅘	C. (100 F.)	3 per cent.
	38	C. (100.4 F.)	2 per cent.

SUMMARY

Type of cases with fever of undetermined origin are briefly presented because of the diagnostic difficulties encountered and because of the very practical considerations involved. It is not claimed that all means of investigation known to medicine have been available for clearing up these cases. The etiological possibilities involved are briefly discussed in a general way.

That the elevation of temperature above the average normal in some of these individuals is normal for them cannot be assumed or denied on the evidence available. Rectal temperatures taken at the same time as the oral ones are indicated to aid in solving the question. Careful and continued temperature studies on many other chronic diseases besides tuberculosis would be of great value.

Such cases as are herein discussed, while deserving all suitable treatment as well as investigation, should not be diagnosed as tuberculous for an indefinite period just because no other cause has been found.

This study included several other cases, but lack of space prevented their publication.

The Cecocolic Sphincteric Tract*

I. SETH HIRSCH, M.D.,
New York,
Director X Ray Department, Bellevue and Allied Hospitals

The purpose of this paper is to call attention to certain anatomical, physiological and clinical data in reference to a certain portion of the colon just distal to the caput coli known as the cecocolic sphincteric tract. This tract is but one of a variety of anatomical formation which, both in the lower animals and in man, has for its important object the retention of the cecal content for such a time as is necessary for the complex digestive changes to take place. Its significance in the human has not been appreciated until now. Röntgen ray studies, however, would indicate that this tract functionates to a greater or lesser degree in human beings and that by virtue of its anatomical markings, physiological manifestations, and pathological stigmata it must be taken into consideration in the studies of the caput coli, a portion of the bowel of great importance, which may be said to bear the same relation to the large bowel as the stomach does to the small bowel.

It is not necessary to enter into a detailed description of the comparative anatomical features of this portion of the bowel, which has been treated elsewhere (1). These studies show that even when the cecum is absent, as it is in about twenty-five genera of mammals, the commencement of the colon is separated by the ileocecal sphincter, from the ileum on one hand, and by another more or less demarcated sphincteric tract, the cecocolic sphincteric tract, from the remainder and colon on the other. Between these sphincters is the cecal colon.

According to Huntington, the vermiform appendix in man and the higher primates suggests that at one phylogenetic period the forms of this order or their immediate ancestors were largely or entirely herbivorous and possessed a more extensively developed cecal apparatus than their omnivorous descendants of today.

From the viewpoint of function, Keith states that the ileocecal region of the fully developed mammalian cecum (as exemplified in the rabbit and cat) may be divided into three parts:

1. That portion of the cecum which lies above the ileocolic opening, called the cecal colon. It is usually regarded as the beginning of the ascending colon and corresponds to the primitive cecum of the lower vertebrates.

2. That portion of the cecum which lies below or proximal to the ileocolic orifice, which is the true cecum, arising as a diverticulum from the cecal colon.

3. The apical or appendicular portion of the cecum which has a narrower lumen and thicker walls—the appendix.

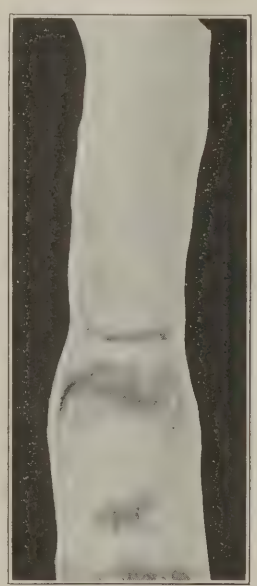


FIG. 1.—Ileocolic junction of the simple type (Nandinia binatata). There is a ridge of thickened musculature and a valve at the junction of the ileum and the colon, which is of slightly larger lumen. There is no dilatation of cecal pouch.

The same three divisions exist in the human cecum,[1] excepting that whereas in the rat there is an additional sphincteric ring between the cecal colon and the cecum, which may be called the intercecal sphincter, in the human being this sphincter is represented by a vestigal strip of muscular fibres, the retinacular bands, which form the frenulæ of the valves.

In the human being it is generally considered that the ascending colon begins above the ileocolic orifice. There is evidence which would indicate that this is not a correct view, but that there exists above the cecal colon, a sphincteric tract, which though imperfectly developed still functionates in a greater or less degree and corresponds to the cecocolic sphincteric tract so well developed and functionally active in many vertebrates, particularly those which live on a mixed or vegetable diet, as has already been pointed out in the birds, horse and rodents.

Even if the actual anatomical conformation cannot always be demonstrated—the site of this tract is made manifest by contractures which are important in the normal and abnormal functioning of this portion of the colon.

ANATOMICAL EVIDENCE

The examination of the cadaver shows, in a number of cases, particularly when the intestines are hardened *in situ*, and more strikingly in children, between the gas filled cecum and the true ascending colon an area, situated from one to two and one half inches above the ileocolic orifice which is firmly contracted and empty, in marked contrast to the gas distended caput.[2] This portion of the bowel has a narrower lumen than the cecum below and the colon above. Its wall is thicker and its musculature firmer. Its color is also different from the adjoining portions of the bowel. (Fig. 9.)

Figure 10 from *Quain's Anatomy*, shows the contracted commencing segment of the ascending colon in a specimen hardened *in situ*. The cecum, with its appendical opening, the cecal colon above the ileocolic orifice, and the contracted portion above the cecal colon are shown in a specimen, intended really to show the relations of the ileocolic orifice. So also in the specimen from Professor Hunting-

*From the X Ray Laboratory of Bellevue Hospital.

[1]At a certain period of embryonic life the human cecum is very long and resembles that of the rodents in its structure.

[2]The presence of this constricted area would explain the accumulation of gas in the cecum in a large percentage of individuals in life in greater quantity than in the upper part of the ascending colon. The entry of this gas into the ascending colon is impeded by the sphincteric nature of the muscular wall of the cecocolic tract.

FIG. 2.—The lower end of the small intestine with the cecum and part of the large intestine of a lizard. (Iguana tuberculata). The small intestine terminates in a slitlike aperture at the edge of a ridge that projects for some distance into the cecum, forming a valve, calculated to prevent any return of food into the ileum. The orifice is marked by a bristle. At one side, this valve projects into the small blunt rounded end of the true cecum, at the other into a large chamber—the cecal colon. This is shut off from the further portion of the intestine by a transverse partition, in the centre of which is a conical valvular prominence, which by a rounded puckered orifice opens into the large intestine. Below this prominence are valvular folds of mucous membrane, projecting into the intestine like a series of shelves diminishing in diameter and producing a series of spiral passages. The caput coli (cecum and cecal colon) is here as a separate viscus with a valve between it and the ileum and another between it and the colon.

FIG. 16.—Photograph of specimen of dilated caput coli due to spasm of the cecocolic tract (Wilkie).

ton's collection, this narrowed area may be demonstrated (Fig. 5).

PHYSIOLOGICAL ACTION

According to Rutherford, the lower end of the ileum is controlled by a purely sphincterlike action of the circular intestinal muscle of the orifice. The musculature of the terminal part of the ileum extends for nearly four inches from the orifice. The contraction of the circular fibres keep the aperture closed till the condition of the contents, on one or the other side of the sphincter, initiates a reflex which relaxes the circular fibres, allowing the aperture to open and discharge more or less of their contents. This process may be assisted by the contraction of the longitudinal fibres.

Through the ileocolic sphincter, flatus and the semifluid contents of the ileum are discharged automatically, at a rate depending on the degree of peristalsis, into the cecal colon. The actual opening of the sphincter seems to be the final part of a wave of peristalsis along the ileum. The ileal peristalsis ceases at the cecal colon.

In most animals the cecal colon acts as a distributing chamber, directing some of the contents into the true cecum and some into the ascending colon. Whether or not the retinacula really exercise a function in the human and the cecal colon acts as a distributing chamber under normal conditions as it does in the lower animals is still a question.

It is logical to believe on a comparative anatomical basis and on studies of human cases in ulcerative disease that the valves and retinacula about the ileocolic orifice may, under certain conditions, also functionate in directing the ileal contents of the cecalcolon, through the cecocolic sphincteric tract into the colon and that contraction of these bands may shut off the true cecum.

The cecocolic tract exhibits its physiological function—to retard the egress of the cecal contents into the ascending colon, until such time as cecal digestion and absorption be complete. It does this by virtue of its anatomical characteristics of a narrow lumen and its physiological characteristics of tonic contraction. Materially contributing to the same end are the anastaltic movements of the proximal colon.

That the point of origin of peristalsis of the true proximal colon is in the cecocolic tract may be proven by administering a small bismuth enema to a patient placed in a favorable position with the rectal tube *in situ* so that the enema may be expelled and the colonic peristalsis studied. First the distal colon contents are expelled into the pelvic colon; then a ring of contraction (not haustration) is visualized in the colon at a point in the cecocolic tract which advances towards the distal colon and removes the contents into the distal colon. Then there is a contraction of the cecum and expulsion of content into the proximal colon. These direct movements do not, however, compare in frequency with antiperistaltic waves which, at first at least, appear to be the predominant movement. A ring of contraction appears in the transverse colon which move towards the cecum. After several antiperistaltic waves there is a segmenting period with the formation and reformation of haustral segments. Then

FIG. 3.—The termination of t ileum and the beginning of colon of an ostrich. Between ileum and colon there is a w demarcated chamber correspo ing to the cecal colon of m mals. It is separated from ileum by a sphincter, the il colic, and from the colon by portion having a narrowed lum called the cecocolic sphincte tract. Two long ceca open fr the cecal colon by a common fice, guarded by a strong ce sphincter.

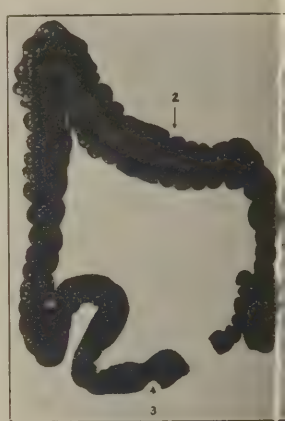

FIG. 11.—Diagram of co showing: 1, sphincteric tract a 2, the location of the sphincter Cannon, Boehm, Elliot, Smit Roith and others. A thicke circular muscular coat was fou at this point by Rost. FIG. 14.—Spasm of the cecoco sphincteric tract in an append inflammation (George).

perhaps further antiperistalsis and then the direct peristaltic waves.

The true proximal colon extends therefore from the cecocolic sphincteric tract to a point beyond the hepatic flexure, in the right half of the transverse colon where a sphincter is located (Rieder, Cannon, Elliot, Smith, Roith. Rose and others), which when stretched by distention of bowel begins to pulsate. (Fig. 11.)

NERVOUS CONTROL

It is well known that the ileocolic sphincter is controlled like the pyloric sphincter through the sympathetic nervous system and that stimulation of the inferior mesenteric plexus causes not only contraction of the sphincters, but inhibition of peristalsis of the ileum and colon.[3]

The manner in which the activity of the cecocolic sphincteric tract is controlled is not known. It appears normally to be in a state of contraction. It receives no motor impulses whatever. Stimulation of the sympathetic splanchnic nerves, supplying the proximal part, does not cause any change, thereby differing from the ileal sphincter in which contraction is produced. It is subject to numerous reflex influences. Perhaps its activity is controlled through chemical stimulus acting through local nerve mechanism in the wall of the colon.

This myogenic nerve control may be from a nodal centre in "Auerbach's collar," which surrounds the ileocecal junction. It is through this tissue, which contains elements to be grouped with Auerbach's plexus, that the central nervous system exercises its control over many of the complex movements of this region. In the rat there is an extension of this collar both on the anterior and posterior aspects of the colon. In the lower animals the action of the intercecal sphincter (between the cecal colon and cecum) and of the cecocolic sphincteric tract are synchronized when the latter is closed, the intercecal sphincter is open and vice versa (Fig. 7).

A synchronism in action exists between the action of the ileal sphincter and the cecocolic sphincteric tract. A disturbance between the synchronized action of these sphincters may result in disturbed physiological function, which may be a factor in the production of disease, as will be shown later.

FIG. 12.—Cecocolic sphincteric tract—enema examination. At a point about three inches above the base of the cecum extending distally for a distance of about two and one half inches is a portion of the bowel having a diminished lumen and small haustrations. The cecum and terminal ileum are well filled.

FIG. 13.—The narrow lumen at cecocolic sphincteric tract may be seen at a point about two and one half inches above the base of the cecum. It extends over an area of about one and one half inches, giving way into the proximal colon. Enema examination—manual pressure.

PATHOLOGY

Investigation shows that developmental constricting bands, pericolitis, simple ulceration, tuberculous ulceration, fibrous stricture and carcinoma, when found in the ascending colon, are most commonly situated in the cecocolic tract. The liability of this portion of the bowel to pathological processes may be explained by several reasons:

1. That it is a vestigeal structure.

2. That its lumen, because of both anatomical and physiological narrowing, is particularly vulnerable to disease, a characteristic which it has in common with other points of luminal narrowing, such as are found in the esophagus

[3] The proximal colon does not receive any motor impulses. Elliot and Smith state that in carnivora such as the cat and dog, stimulation of the sacral visceral nerves causes constriction and emptying of the large bowel from cecum to rectum. In herbivorous animals and in man, the effect extends only to the distal parts of the colon — the cecum, ascending and hepatic part of the transverse colon are outside the influence of this mechanism.

in the pyloric end of the stomach, and in the pelvirectal junction of the colon.

3. That it is a region of great functional activity.

INTERMEDIATE NON-VASCULAR FOLD

FIG. 4.—Ileocecal junction of monkey (cercopithecus) showing the narrowed portion of bowel above the ileocecal junction—the cecocolic sphincteric tract. (Huntington, Columbia University Museum).

SPASM

Spasm of the cecocolic sphincteric area is a common phenomena. Such spastic contraction may be due to disease in the area itself, to the presence of

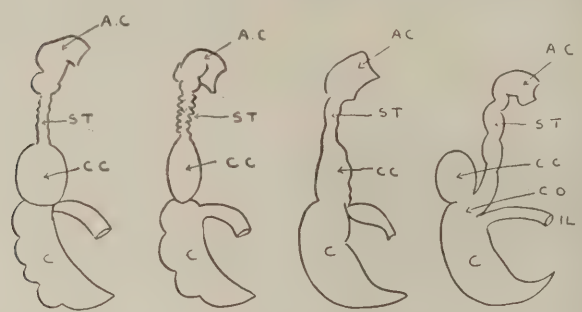

FIG. 7.—Illustrating the four functional states of the ileocolic region of rats. In A and C the ileocecal sphincter is closed, in B and D it is open. In C and D the cecocolic sphincteric tract is open, in A and B it is closed. In A and B the intercecal sphincter is closed, in C and D it is open. In C the cecal colon and cecum are practically one chamber. A C, ascending colon; S T, cecocolic sphincteric tract; C C, cecal colon; C, true cecum. (Arthur Keith).

irritating contents in the ileum or cecum, to disease of the terminal ileum, appendix, cecum, or the cecocolon, or to such pathological conditions, as ulceration or tumor of other portions of the colon

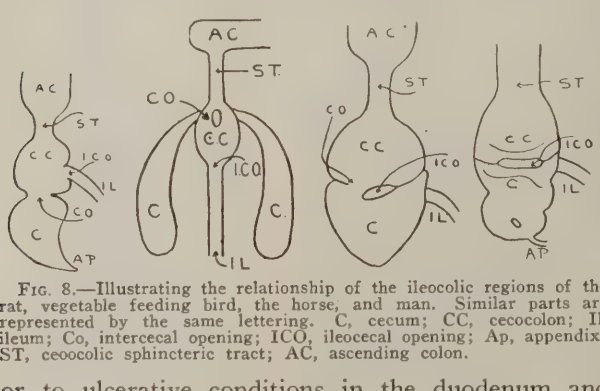

FIG. 8.—Illustrating the relationship of the ileocolic regions of the rat, vegetable feeding bird, the horse, and man. Similar parts are represented by the same lettering. C, cecum; CC, cecocolon; Il, ileum; Co, intercecal opening; ICO, ileocecal opening; Ap, appendix; ST, ceoocolic sphincteric tract; AC, ascending colon.

or to ulcerative conditions in the duodenum and functional conditions of the stomach, or as a part of a general or local vagotonia. Such spastic contraction plays an important part in the production of cecal stasis. Leaving out of consideration neoplastic obstruction, ileal stasis (meaning delay of emptying time of the ileum) has been ascribed to incompetency of the ileocolic sphincter, and ileal adhesions including Lane's kink. Perhaps more important than any of the above causes is spasm of the cecocolic sphincteric tract.

It is only by spasm of this portion of the colon that cecal retention can be explained in the presence of the increased peristaltic hyperactivity of the cecum, such as is associated, for instance, with appendicular disease. The marked hyperactivity of the cecum in such cases may be evidence of attempted compensatory activity in an effort to overcome the spasm. If in the presence of spasm the ileocecal valve is competent there follows a gradual dilatation of the caput coli with its attending stasis and the sequela of a low grade inflammatory condition with the formation of pericolic adhesions, which further

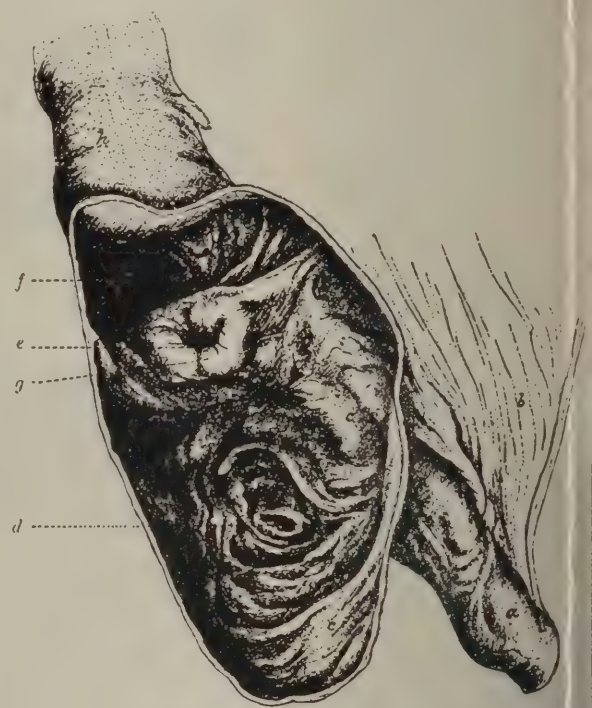

FIG. 10.—Proximal colon, hardened *in situ* (*Quain's Anatomy*) f, cecal colon; e, ileocecal orifice; c, cecum; d, orifice of appendix a, ileum; h, cecocolic sphincteric area.

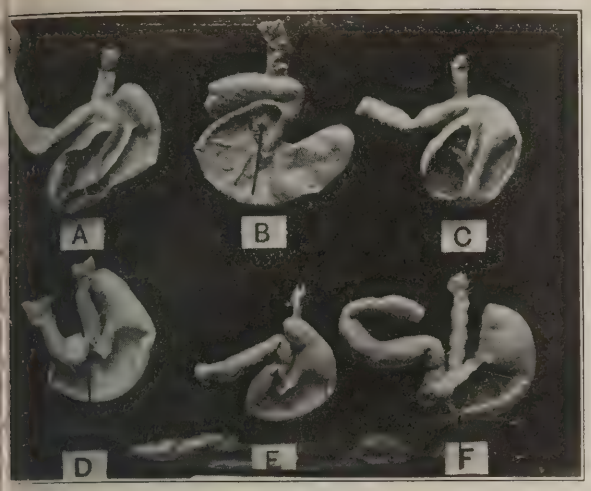
increase the stasis, and thus a vicious circle is produced. The appendix may become involved in the low grade inflammatory process. If, on the other hand, the ileocecal valve is incompetent, then spasm of the cecocolic tract results in the regurgitation of the cecal contents into the ileum with the well known clinical manifestations of intestinal toxemia. The prolonged retention of the cecal contents has the effect of slowing down on the onward passage of the intestinal contents along the rest of the colon. The changes characteristic of the spastic or dyskinetic form of constipation may be associated with spasm of the cecocolic tract. The relief of spastic constipation by atropine is produced through relaxation of this hypertonicity or spasm.

It is further conceivable that severe and sudden spasm may occur as a result of severe and acute irritation of the terminal ileum. If the ileocecal valve is competent, this would lead to overdisten



IG. 6.—The ceca of a series of white rats killed one-half, one, two, e, six, forty-seven hours after food. The ileum opens into the of the cecum, a segment of the colon—physiologically, distinguish- from the apical part or true cecum and known as "cecal colon" in ch the muscles act independently of those of the colon, from the of the cecum. Between the cecal colon and cecum is a definite ncter muscle. For an hour or more after feeding both cecal colon the cecum are distinct and separate chambers but as digestion eeds the chambers fuse into each other.

n of the cecum—and the appendix. The sensation pain would then appear as a result of this over- tention, for the pain is due, not to contracture, to increased tension of the bowel with muscular etching. The overdistention would produce en- rgement and on this fertile soil the organisms uld proceed to carry out their rôles in the pro- ction of acute appendicular and cecal inflam- tion.

G. 5.—Ileocecal junction (human) showing the narrow portion of colon (indicated by the arrow)—the cecocolic sphincteric tract. portion of the colon between the ileocecal orifice and the narrowed is the cecal colon. (Huntington).

Should the spastic contraction be relaxed before severe distention or congestion has taken place, the symptoms may be relieved. Such cases are clinically not rare. They are often diagnosed as appendicular colic. The pain is not associated with a rise of pulse or temperature or a change in the blood picture. The finding of a normal appendix by the surgeon in such cases may be explained on the theory of such spasm. There are a number of cases in which, a short period after the removal of the appendix, the local and reflex symptoms recur. It is possible that spasm of the cecocolic tract may be responsible for clinical symptoms in such cases. The spastic contraction of the tract being relieved by the anesthesia may explain why this condition

FIG. 9.—Cecocolic sphincteric tract in normal child. Located at a distance of eight and one-half cm. above the lowest part of the cecum it is seen as a narrow tract three and one half cm. long. It has its origin at a point about five cm. above the ileocecal orifice. The portion of the colon below the beginning of this narrow tract is divided into two parts by the ileocolic orifice. In the contracted area there are four haustrations on the mesial aspect. These, however, are not symmetrical, those on the outer aspect being somewhat larger. The portion of the colon below the contracted area is of dark brown color; that above the contracted area is of a reddish brown color. The contracted area is of a whitish pink color.

has not been previously demonstrated by the surgeon.

A spastic contraction of the cecocolic sphincteric area can be demonstrated röntgenologically in these cases where no röntgenological evidence of pathology of the appendix is evident. Both in these cases and in those in which there has been a recurrence of symptoms (pain in the right iliac region, distention, fullness, constipation and reflex gastric symptoms) after the removal of the appendix, for socalled chronic appendicitis, the examination discloses the presence of a spastic contraction of the portion of the colon, which corresponds to the site

FIG. 15.—Spasm of the cecocolic tract in colitis. Note the overdistention of cecum and appendix. Enema examination.

of the cecocolic sphincteric tract, associated with definite and more or less prolonged cecal stasis.

On the other hand, a spastic state of this tract can also be demonstrated röntgenologically in cases showing definite röntgen evidence of appendicular disease. Not only has this been demonstrated in our own cases, but it may be seen in the illustrations of others (*George and Leonard*—Figs. 252, 282, 287, 293).

This indenture or incisure is situated at a distance of one and a half to four inches from the ileal entrance into the cecum. Occasionally this contracted area has been noted nearer to the hepatic flexure when the caput is dilated. Manual pressure fails to obliterate this contraction. The area may be from one to two and a half inches in length, or may be a short complete incisura. It is frequently hidden in plate examinations by the haustra above and below it, but may usually be demonstrated by fluoroscopic palpation and the examination in the oblique position.

The break in the bismuth shadow is usually distinct. Below it is seen the shadow of the cecalcolon and cecum, usually of considerable size; while above it is the ascending colon shadow. In cases where this spastic area stands out with great sharpness and clearness and shows a persistency and there is röntgen evidence of an abnormal appendix, the onset of an acute attack is not far off.

Spasm of the cecocolic tract may thus be as important as any of the causes usually given for appendicitis.

In a proportion of cases duodenal ulcer spasm of the cecocolic tract may be observed. In s of these cases the evidence of appendicular ease was well marked. In others, the appen had been removed—but a spastic state of the c colic tract existed. It is, of course, not safe to i even in the instances of a constant concomitant a relation of cause and effect exists and still les conditions not invariably associated, neverthel it is justifiable to infer that spasm of the cecoc tract may have some bearing on the clinically rec nized association of duodenal ulcer and disease the appendix. So that it may be concluded in certain individuals spasm may be produced in cecocolic tract. This spasm may lead to cecal st and appendicular inflammation. The appendect may not, however, remove the cause of the spasm.

There are also cases of pure spasm of this t followed by slow but marked dilatation of the ca and even the small intestine. The contractio localized and may vary in extent from one to se inches. The constriction may be so marked a produce actual obstruction. Cases have not in quently been described in which all the symptom the intestinal obstruction were present; and ye operation no obstruction was found.

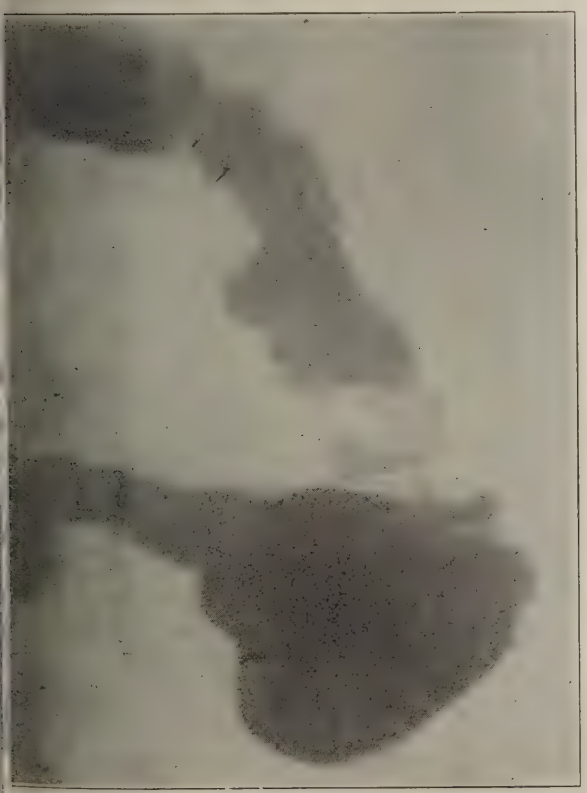
In some of the cases the cecal colon, cecum small intestines were found distended and a por of the colon distal to the cecocolic tract norm yet no obstruction could be discovered at the p of junction of the distended and collapsed bo as in a patient operated on by Barber.

This portion of the colon is involved more t any other part in congential peritoneal bands. presence of these peritoneal bands are not respo ble for the cecal stasis because they are freque

FIG. 17.—Spasm of the cecocolic tract in tuberculous ulcerat ileum.

FIG. 18.—Cecocolic sphincteric tract with ileum adherent.

n in newborn infants. It is evident that there st be another factor at work in the production the stasis, and that factor undoubtedly is spasm. e bands plus spasm due to any cause leads to a ited condition of the cecum.



IG. 19.—Scirrhus carcinoma of the cecocolic sphincteric tract. mpetency of ileocecal valve.

Jackson in 1909 recorded a series of cases previously diagnosed as chronic appendicitis in which at operation the appendix was found to be normal, but in each case he found a thin transparent vascular membrane stretching from the right flank over the front of the ascending colon. He divided the membrane and stated he was able to give these patients sure relief. This membrane was believed by Jackson to be responsible for the symptoms, and yet this membrane which had been previously described by the Jonnesco is found in about fifteen per cent. of bodies, in the fetus, and in children—in individuals who never exhibit symptoms in the right iliac fossa. Is it not more logical to believe that the symptoms in Jackson's and in all such cases were and are due to spasm—the fold being predisposing factor towards the production of disease—and that when, because of the stasis, a chronic inflammatory condition was instituted, this process converted a

FIG. 20.—Carcinoma cecocolic sphincteric tract from specimen in pathological laboratory, Bellevue Hospital, through courtesy of Dr. Symmers.

developmental membrane into an inflammatory one and that then the inflammatory membrane plus the spasm produced the stasis?

INTUSSUSCEPTION

It is generally stated that intussusception is produced by an irregular peristaltic movement, at a moment when a portion of the bowel is sharply tonically contracted. The active part of the process of invagination is taken by the outer layer, and the tendency is for the bowel to creep over a narrowed portion. This may be demonstrated by electrically producing a contraction of a portion of the colon of an animal when its invagination by the adjoining part may be observed.

There is a form of intussusception belonging to the ileocecal variety (the commonest of all varities), in which the inversion is said to begin at the junction of the cecum and colon, the cecum and ileum forming

the intussusceptum, the colon above folding over the cecum and ileum. The presence of the cecocolic sphincteric tract serves to explain this form of intussusception. In the presence of irregular peristaltic activity this constricted area presents the necessary condition for the invagination.

INFLAMMATION

The portion of the colon corresponding to the site of the cecocolic sphincteric tract appears to be a favorite site of colitic ulcerations, fibrous stricture and tuberculous disease. Cramer has pointed out that the upper part of the cecum and the lower part of the ascending colon are frequently the site of inflammatory processes.

Several observers have directed attention to the frequency of a localized acute inflammation in the cecocolic region without ulceration. These cases are usually diagnosed as appendicitis and operated in as such; but the appendix is found healthy and definite localized inflammatory swelling is found in this portion of the colon.

Mollison and Cameron in a series of fifty consecutive postmortem examinations found adhesions in the region of the cecum and the ascending colon in thirty-five cases. Such adhesions are often erroneously ascribed to a former attack of acute appendicitis. In only three cases of the thirty-five observed were the adhesions definitely grouped around the appendix.

Localized ulcerations have been described in this tract and in the cases of perforation by ulcer in the ascending colon the location of the ulceration has been most commonly in this area.

It is a question for serious consideration whether or not these ulcerations and adhesions have their origin in inflammation of the cecocolic sphincteric tract and whether the inflammatory condition is not predisposed to take place in this region by virtue of its tendency to spasm.

TUBERCULOUS ULCERATION

The commonest site for tuberculous ulceration is in the terminal ileum. The next is the lower part of the ascending colon. Eisenhardt found lesions in fifty-six of one thousand tuberculous subjects. Herscheimer found them in all but one of fifty-eight cases of phthisis. According to Nummery the ulcers are most commonly found in the cecum and ascending colon. In one hundred collected cases of hyperplastic tuberculosis the cecum and ascending colon were involved in eighty-seven. The analysis of the latter cases, however, will show that the majority of ulcerations are really not in the true cecum, but above the ileocecal valve and in the region of the cecal colon or, most commonly, in the cecocolic tract. When present in this region they produce the röntgenological signs of irregular filling defects—hypermotility of the ascending colon and irregular areas of spasm in the tract. Ulcerative disease of the terminal ileum may, however, also produce marked spasm of the cecocolic tract. In the case shown in the illustration (Fig. 17), the patient was a man of forty-eight years. The intestinal lesion was not suspected. The röntgen examination showed the marked constriction of the lumen of the colon in the regions corresponding to the site of the cecocolic tract.

At operation an ileal tuberculosis was found. Nothing could be found corresponding to the area of defect in the ascending colon. Evidently, then this was a pure spasm of the cecocolic tract.

The difficulty in obtaining a shadow of the cecum in tuberculous ulcerative processes is well known. The contents of ileum are partly regurgitated into the cecal colon for the valve is usually incompetent in these cases or rushed through the cecocolic tract into the colon. The shadow of the cecum can either not at all be visualized or visualized momentarily and rarely completely. This sign has been explained on the basis of spastic contraction of the true cecum. It is more logical to consider that the difficulty in filling the cecum in these cases may be due to spasm of what in lower animals corresponds to the intercecal sphincter—the retinacular bands. The ileal content then passes directly into the cecal colon and through the cecocolic tract into the ascending colon without entry into the cecum just as it does normally in some animals. The muscular bands do not, however, apparently always, functionate perfectly for a leak into the cecum may take place with incomplete outlining of this structure.

CANCER

It is generally recognized that the areas of narrowing in the lumen of the gastrointestinal tract are sites of predilection for carcinoma. It would appear from the published records of malignant disease of the colon that carcinoma of the ascending colon is relatively uncommon; though the cecum is considered to be a frequent site for malignancy.

In the London Hospital statistics there were placed in the ascending colon out of 188 cases and in Lichtenstein's series 6 out of 121 cases of carcinoma of the colon. In other words, 12 out of 309 cases—less than 4 per cent. There were, however, 41 tumors situated in the cecum out of 188 cases and 32 in the cecum out of 121 cases, and 17 out of a series of 72 cases reported by Clegg, making 90 cases of cecal carcinoma in a series of 381 cases or 24 per cent. If the cecal and ascending colon tumors are taken together and the 283 cases of the series of 625 collected by Tuttle are counted there are 385 cases of carcinoma in the cecum and ascending colon in a series of 1,006 cases. The comparative frequency of cancer in this part of the colon has therefore a value of 38 per cent.

Analysis of tumors of the colon, situated at a point distal to the ileocolic valve, which have been classed as cecal, will, however, show when anatomical boundaries above described are recognized, that the majority of these tumors are really located in the sphincteric area.

The following factors must, according to D. P. D. Wilkie, be taken into consideration in the determination of the exact anatomical position of lesions which obstruct the lumen of the bowel in the region of the ascending colon: first, the variety of tumor, whether it is of the stenosing scirrhous type or of the fungous, infiltrating type; second, the degree of obstruction produced by the lesion; third, the tendency of the disease to infiltrate and cause shrinkage of the wall of the gut; fourth, the competency or incompetency of the ileocecal valve. Thus a scirrhous carcinoma may involve only a ring of the bowel

wall, producing marked stenosis of the lumen, but if associated with a competent ileocecal valve, there may result such a dilatation of the cecum and cecal colon as to displace the growth upward and make it appear as if the growth was located close to the hepatic flexure, when it really has its origin at a much lower point. If the growth be of the infiltrating type with but little obstruction of the lumen, the shrinkage of the caput coli may be such as to make it appear that the lesion is at the level of the ileocecal valve when it really has its origin at a higher point, in the cecocolic sphincteric area.

If there is an incompetency of the ileocecal valve, there will be no displacement of the tumor bearing area even though the tumor is of the scirrhous type, though the terminal ileum will undergo marked distention.

SUMMARY

1. The caput coli may be divided into the cecum and cecal colon.
2. The retinacular bands supposed to be vestigeal strips may actually functionate and by spasm partly or completely shut off the true cecum from the cecal colon.
3. The cecal colon acts as an imperfect distributing chamber between the cecum and the cecocolic tract.
4. There is anatomical comparative anatomical, physiological, radiographic and pathological evidence pointing to the existence of a region in the human colon which corresponds to the proximal part of the colon in most herbivorous and omnivorous air breathing vertebrates, which is normally in tonic contraction.
5. This cecocolic sphincteric portion of the colon exhibits an active repulsion of the intestinal contents, until such time as cecal digestion and absorption are complete.
6. The contraction and relaxation of this portion of the bowel is undoubtedly regulated by chemical changes in a manner similar to the control of the pyloric opening and closing.
7. This sphincter may be thrown into the spasm with the production of cecal distention and stasis and thus initiate inflammation and ulceration.
8. The cause of the spastic condition is not always removed by appendectomy, for it may be demonstrated in cases in which there is a reappearance of symptoms after removal of the appendix.
9. The pathological lesions of the alimentary tract are more likely to occur at the points at or just proximal to regions of anatomic constriction, as in the esophagus and stomach. The cecocolic sphincteric area of the colon may be considered to be one of these areas.

Clinical and Experimental Observations on Blood Sedimentation

M. E. ALEXANDER, M.D.
Waterbury, Conn.,
Visiting Physician to Waterbury Hospital.

GENERAL

Since Fahreus (1), in 1916, drew attention to the phenomenon of increased sedimentation of the red blood cells in pregnancy, a generalized interest was awakened in the subject. It was soon afterwards shown that the phenomenon is to be seen in a variety of conditions, but especially in individuals who suffer from some more or less acute form of inflammation. From the historical viewpoint, this discovery of Fahreus was far from new. The observation can be found in most medical works of the eighteenth century and also of the nineteenth. Under the name of Crusta Phlogistica or Crusta Inflammatoria or Buffy Coat, it can still be found in many of the books of medicine published in the latter half of the last century. Even Sir Alfred Garrod (2), who did such accurate chemical work in connection with uric acid in the blood in gout, mentions it as being of frequent occurrence in acute rheumatism. The relationship of acute inflammations with increased blood sedimentation was well brought out by John Hunter (3) in the last decade of the eighteenth century.

This remarkable investigator observed it especially in acute rheumatism in which connection he mentions that "thirty seconds after venesection there appeared on the surface of blood a layer of bluish transparent lymph, although no coagulation had yet started." J. F. Palmer (4), the editor of Hunter's works, makes some very interesting remarks in connection with the observation given above. He says, "Nothing can be more clearly proved than that there exists in the blood a greater disposition to separate into its component parts in inflammation than in the healthy state." Hunter has also shown that the sedimentation of the blood from an inflamed part does not differ from that from a noninflamed part of the same individual.

With the advent of Virchow and his cellular pathology, all humoral doctrines were relegated to the past and the observations given above were forgotten entirely until brought back to prominence by Fahreus. The same phenomenon of increased blood sedimentation was found apparently independently by Plaut (5) in various forms of psychosis, especially in general paresis. Then followed the observations of Linzenmeier (6) and a great many other investigators, mostly in Germany.

As to the exact mechanism of the phenomenon, we are still at a loss to explain it satisfactorily. The most widely accepted explanation is that it depends upon the fibrinogen content of the blood, since in defibrinated blood the sedimentation proceeds much more slowly. This is also quite in keeping with Hunter's original explanation. It is quite clear, however, that this is not the only factor, since it also depends greatly on the globulin content of the blood.

According to W. and H. Lohr (7), the phenomenon is greatly dependent upon the viscosity of the blood. It has also been assumed to be produced by specific ferments similar to those playing a part in the Abderhalden reactions; also due to surface tension, lipoids, colloids, and other unknown factors. It seems as if a great many more investigations will have to be carried out before this most interesting phenomenon will be satisfactorily explained. It may be of interest to mention here that among different animal species, we find under normal circumstances extreme differences of rate of sedimentation of the red blood cells. In the horse, for example, the sedimentation is exceedingly fast while in cattle it is extremely delayed.

PERSONAL OBSERVATIONS

The technic I employed in these observations was that of Linzenmeier. The test tubes are about 6.5 cm. in length and have a calibre of 5 mm. The tubes are marked at 1 c. c. and also in 18 mm. below this mark (Fig. 1). Coagulation is prevented by first putting .2 c. c. of a five per cent. sodium citrate solution in each tube and adding blood to the 1 c. c. mark. Gentle shaking or stirring is all that is necessary. The citrate merely serves the purpose of preventing coagulation; oxalated blood may also be used. Whenever time intervals are mentioned in this paper, they have reference to the number of minutes or hours that it took for the red blood cells to separate and settle to the 18 mm. level. By accelerated rate of sedimentation is meant precipitation to the 18 mm. level in less than one hour. If it took less than thirty minutes, the rate of sedimentation may be said to be very much accelerated.

EFFECT OF TEMPERATURE

Sedimentation proceeds the fastest at body temperature. At room temperature (20° C.), the rate of sedimentation is approximately eighty per cent. of that at 37° C. At 45° C. no sedimentation at all takes place, while at 0° C. it is exceedingly slight. It will therefore be seen that for all clinical purposes, room temperature answers the purpose best.

EFFECT OF H ION CONCENTRATION VARIATIONS

Fairly wide variations of the H ion concentration of the blood failed either to accelerate or retard its sedimentation. Similarly negative results were found after the addition of various isotonic salt solutions. N/5 solutions of sodium chloride, potassium sulphocyanate, potassium iodide, sodium sulphate, and sodium citrate when added in equal amounts to a given blood cause no alteration in the rate of sedimentation. The addition of bile, even in very small amounts, seems to delay sedimentation to a very marked extent.

VARIOUS MEDICATIONS

The effects of quinine, salicylates, and arsenic on the phenomenon were studied. Three groups of three patients each were used for this purpose. Each one of the first three patients received five grains of quinine every four hours for six doses. No apparent effect on the rate of sedimentation was noted. Three other patients received, each, ten grains of sodium salicylate every four hours for four doses, with similarly negative effects on the test. The last three patients of the group were given one fortieth grain of arsenious acid four times daily for four days. The sedimentation time was not altered. Profuse sweating was induced in four patients by means of the electric bake. It was found to have no effect on the rate of sedimentation.

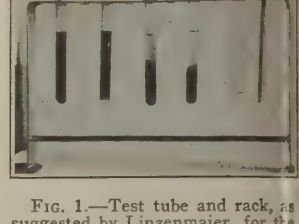

FIG. 1.—Test tube and rack, as suggested by Linzenmaier, for the performance of the blood sedimentation test.

As I have partly shown in a previous communication (8), neither small nor large doses of either galvanic or faradic currents alter the blood sedimentation in a given case.

OBSERVATIONS ON DIAGNOSTIC VALUE OF THE TEST

The material for this paper is based on over four hundred tests made on 362 different patients. Since these tests were performed on a great variety of affections, I deem it inadvisable to go into details about all of them but will confine myself solely to those conditions in which I found the rate of sedimentation to be accelerated. A general idea of the nature of the cases investigated can be gathered from examining the accompanying table (Table I).

SEDIMENTATION TEST IN PREGNANCY

An interesting group of cases in this series is the pregnancy cases. Forty such cases were examined for this test. Thirty-two of these cases were of three or more months' gestation, while the remaining eight were of less than three months' duration. As will be seen by examining the accompanying table (Table II), no instance of pregnancy beyond the third month presented a delayed rate of sedimentation. The average rate for the thirty cases was twenty minutes, while in a general way it may be said that the farther advanced in the state of pregnancy, the more pronounced is the acceleration of the sedimentation. In cases of pregnancy of less than three months' gestation, the sedimentation test is normal or accelerated to a negligible degree.

SEDIMENTATION RATE IN TUBERCULOSIS

Another important group of cases in this investigation consists of forty-four instances of tuberculous infection. In twenty-two cases of active pulmonary tuberculosis, the sedimentation rate was found to be greatly accelerated, while in twelve instances of healed or completely arrested cases of the same affection, the test was found to be normal. In two cases of early tuberculosis of the kidney and in eight cases of tuberculous cervical adenitis without secondary infection, the sedimentation time was also of normal duration.

25.	7,600	62	0	No exacerbations.

SEDIMENTATION TEST IN ACUTE INFLAMMATION

In twenty-nine cases of acute inflammation, the sedimentation phenomenon was found to be markedly accelerated. This group consisted of ten cases of acute arthritis (acute articular rheumatism), four cases of facial erysipelas, twelve of lobar pneumonia, and three of acute tonsillitis. The temperature in these cases ranged between 100° to 104° and the leucocytosis varied from a very slight (8,600) to a very pronounced degree (46,000). These investigations showed that it was not only elevation of temperature that produced the increased rate of sedimentation, since among the entire group of cases investigated were several cases of temperature of 102° and 103° F. with no corresponding effect on the sedimentation test.

SEDIMENTATION TEST IN ARTHRITIS

Another interesting group of cases consists of twenty-five instances of chronic arthritis. Out of these twenty-five cases, the sedimentation test was found increased in eight individuals. None of the patients included in this group showed any elevation of temperature, nor were any of them confined to bed. But from an analysis of the group, it is quite apparent that the inflammatory process in the eight patients with the accelerated rate of sedimentation still showed some signs of activity. As I have already said, from the general examination, one could hardly have made a distinction between the patients under consideration and the rest of the group whose sedimentation was normal. Six of the eight patients showed marked tendencies towards acute exacerbations of the arthritis at later days. During these exacerbations, the sedimentation rate was extraordinarily accelerated, while the temperature and leucocytes during the same period were elevated only to a very slight degree.

SEDIMENTATION TEST IN SYPHILIS

In twenty cases of syphilis examined, the sedimentation rate was found increased. None of the patients examined were in the first or second stage. They were all in the third or fourth stage of the disease. Six of the patients examined suffered from general paresis and it is in these cases that the rate of sedimentation was most accelerated. In two of these six cases, the red blood cells settled to the 18 mm. level within six minutes from the time the test was performed.

DISCUSSION

From what has been stated above and from the accompanying tables, it may be noted that an increased rate of sedimentation may be found in a variety of diseases and under many diverse circumstances. If, however, we do not forget its limitations, it is my opinion that the described test had great diagnostic value. This is especially true when it comes to a differential diagnosis. The test is of paramount importance in differentiating between inflammation of the pelvic organs and tumors or cysts located in the same region. As we all know, considerable inflammation of the pelvic organs may be present without an appreciable elevation of temperature or pulse rate. It is in just such cases that, given a pronounced acceleration of the blood sedimentation, our diagnosis may safely lean toward an

inflammatory process rather than to a noninflammatory mass. In this connection, it may also be mentioned that the test has been found serviceable in cases of gonorrheal salpingitis where no operation was deemed advisable while more or less acute inflammation existed. When the blood sedimentation came back to a normal level, the Fallopian tubes, at the time of operation, were found devoid of acute inflammation.

Even though the blood sedimentation is not accelerated in pregnancy until after the third month, this test has still a definite value in the diagnosis of this condition. During the fourth, fifth, and even later months, it frequently becomes necessary to differentiate the condition from myomata uteri or cysts. With a normal sedimentation time, pregnancy of more than three months' gestation is very unlikely.

In active tuberculosis, the sedimentation rate is greatly accelerated, but it is not so clear in my mind that the phenomenon is due to the tuberculosis *per se*. These cases are so frequently associated with secondary infection of the bronchi that it becomes difficult to rule out that factor. In tuberculous cervical adenitis without secondary infection, the sedimentation test does not seem to be altered from normal. The same holds true of tuberculosis of the kidney in the early stages. In three cases of tuberculous pleurisy with effusion, the sedimentation test was also found normal. Further investigation is necessary to determine the value of the sedimentation test in tuberculosis.

SUMMARY AND CONCLUSIONS

1. The rate of blood sedimentation was found increased in pregnancy, acute inflammations, active tuberculosis and the later stages of syphilis.

2. In certain cases of chronic arthritis, an increased rate of sedimentation may indicate that the inflammatory process is not entirely subsided and acute exacerbations may be expected.

3. The blood sedimentation test is of great value in differentiating pelvic inflammation from noninflammatory tumors of the same region.

Congenital Absence of the Right Pectoralis Major Muscle

GEORGE B. LAKE, M.D.,

Camp Alfred Vail, Oceanport, N. J.,

Major, Medical Corps, U. S. Army

On March 22, 1923, a young man applied to the recruiting officer, Fort Hayes, Ohio, for enlistment in the Army. A peculiar malformation being noted the man was referred to me for examination, when it was found that the right pectoralis major muscle was entirely missing.

Case.—The patient, H. T., was eighteen years of age, single, born in Ohio. He had been brought up in an orphan asylum, and had no memory of any severe illness or accident. He said the condition of the muscles around the right shoulder had always been as they were at present.

His father was fifty-nine and his mother forty-eight years of age, both of English birth and both living and well, though separated for some years. The patient was the youngest of eight children, one of whom had died and two had socalled weak eyes. Aside from these facts he knew very little about his family history.

Examination revealed an anatomical condition as is shown in accompanying photographs. There was no scar or evidence of surgical removal of the muscle. Function of arm was good. Teeth were of Hutchinson's type. Epitrochlear and postcervical glands were distinctly palpable. Scapulæ were slightly scaphoid. No other physical abnormalities were noted. One Wassermann test was made and reported negative. There was no opportunity to make further Wassermann or luetin tests.

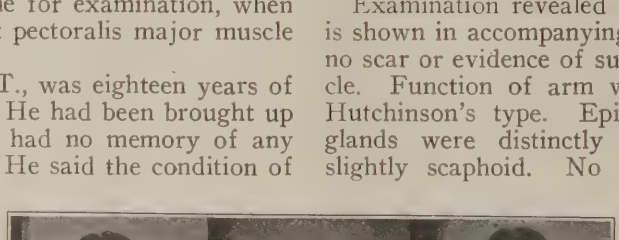

Fig. 1.—Showing anatomical condition of patient's shoulder.

In view of the family history and the clinical findings it is believed that the condition was due to congenital syphilis, latent.

Periarterial Sympathectomy

RUSSELL F. MADDREN, M.D.,
Changsha, China
Attending Surgeon, Hunan-Yale Hospital, Changsha,

The deliberate surgical ablation of the vasomotor erves lying in the tunica adventitia of large arteries as first conceived and practised clinically by Jabou- y in 1889. Claude Bernard, over seventy years ago, d noticed homolateral elevation of the arterial ood pressure after section of the cervical sympa- etic cord, but it has remained for Réne Leriche, of yons, to popularize the operation which he terms riarterial sympathectomy. He recently reported xty-four cases and has "obtained remarkable suc- sses and had complete failures."

The possibility now proved of modifying periph- al circulation and temperature by a simple and fe surgical operation places in our hands a potent erapeutic agency for the treatment of trophic and somotor disorders. Those interested in the sub- ct are referred to the numerous original papers of riche, upon whose work are based all of the arti- s in the rapidly increasing literature of this sub- ct. Tuffier of Paris has performed aortic sympa- ectomy for angina pectoris but emphasizes that, hough the pain is relieved, the pathological condi- n remains and the patient cannot overexert him- f without courting disaster.

Seifert has sounded a note of warning regarding versed effects. Some time must elapse before the act indications and contraindications can be laid wn definitively and, as the conclusions of the pro- sion will be based upon clinical experience, it uld perhaps be well for every surgeon to report individual results.

Subjoined is a brief summary of the first peri- erial sympathectomy performed in China.

CASE REPORT

ASE.—Number 1592. C. Y. S., female, aged nty-six, married, a housewife, was admitted to nan-Yale Hospital on December 21, 1922, com- ining of ulcer of the right foot of nearly five rs' duration. The patient's family history was relevant as far as was ascertainable. She had n married very young, had one child alive and l eighteen months old, and her husband was living l said to enjoy good health. The patient had had ht leucorrhea for the past year. Her past per- al history was otherwise negative.

Her present illness began about five years ago, n she noticed a vesicular eruption over the dor- n of the right foot. The vesicles ruptured and an r gradually developed accompanied by acute n. After a time this pain gradually diminished, the ulcer deepened and extended on to and be- en the last three toes. Discharge became abun- t and foul, and generalized bone and joint pain eloped a little later. The patient was a well de- ped woman of dull mentality. There was no cer- l adenitis, heart, lungs, and abdomen were nega- , and the extremities were also negative except a large deep ulcer on the anterolateral aspect of the right foot involving the last three toes. The edge of the ulcer was everted and its floor covered by much unhealthy granulation tissues. Foul discharge was present.

The clinical diagnosis was ulcer of the foot, probably of syphilitic origin. Laboratory reports showed a three plus Wassermann; urine showed albumin at eight of ten examinations; renal function (average of two tests) twenty per cent. Stool was negative except for ascaris. Blood count was within normal limits. Skiagram showed osteoporosis of disuse.

Operation was performed on December 28, 1922, as follows: Under infiltration analgesia with novocaine and adrenalin, the right superficial femoral artery was exposed by the classical incision for ligation at the apex of Scarpa's triangle. The sheath was opened without injuring the internal cutaneous or long saphenous nerves. No anesthetic was injected into the adventitia (which Meltzer, Odermatt, and others have shown is the only part of the arterial wall possessing pain sensibility). In two cases where he injected alcohol into the wall of the femoral artery, Handley noted no immediate local change in the calibre of the vessel but I feared that novocaine and adrenalin might act differently and so abstained lest premature contraction occur. The adventitia was readily dissected away at its plane of cleavage (the outer elastic membrane) for a distance of about one inch. The decorticated artery at first bulged slightly and then contracted, but not to a marked degree.

Leriche has shown that the phenomenon of contraction is slower in the larger arteries than in the smaller and is particularly tardy in the femoral. In twenty per cent. of Callander's cases it did not occur at all. The wound was completely closed in layers using fine catgut for all buried sutures. We found ablation of the living adventitia technically easier than in the cadaver and much easier than in the dog.

SURSEQUENT NOTES

December 30, 1922: Foot looked better; ulcer cleaner than before; granulation tissue very vascular and bled easily. Swelling was subsiding and the general condition was good. Local treatment of ulcer was given continuously the same as during the week preceding operation.

January 1, 1923: Neoarsenobenzol 0.6 gm. intravenously; no reaction. (This had been withheld previously to observe the effect of operation unassisted by specific therapy.)

January 4, 1923: Neoarsenobenzol 0.3 gm.; no reaction.

January 8, 1923: Foot was much better. Slight swelling over the dorsum was still present and moderately tender.

January 9, 1923: Neoarsenobenzol 0.45 gm.; slight chill in half hour followed by some fever in the afternoon.

January 12, 1923: Patient felt well. Operation wound had healed per primam. Prescription was given for mercury and potassium iodide three times a day.

January 18, 1923: Ulcer was almost well; no pus except between toes.

January 23, 1923: Ulcer was entirely healed. Patient still had some generalized bone pain but *never in the right foot.*

January 25, 1923: Neoarsenobenzol 0.6 gm.; no reaction.

January 30, 1923: Bone pain was still present; most marked in *left* leg.

February 1, 1923: Neoarsenobenzol 0.6 gm.; n reaction.

February 3, 1923: Discharge note. Patient le the hospital with the ulcer soundly healed. Ther was still some general bone pain which was wor in the left (unoperated) leg. She *walked* out. (Ha not reported back to date of writing.)

CONCLUSION

It seems possible that periarterial sympathectom followed by the intravenous injection of arsenobenz will enable us to treat luetic leg ulcers more effec ively.

Mental Reaction to Venereal Infection

MONROE A. MEYER, M.D.
New York

In addition to the fact that severe neurosis may develop immediately following venereal infection, medical literature has recorded the observation that in many persons who pass through venereal disease and are fortunate enough to escape more serious functional mental disorder, there appear minor neurotic reactions or distinct character changes. There has been a tendency, naturally more especially in the case of syphilis, to ascribe these mental reactions to toxic factors producing finer pathological changes in the central nervous system. The following brief case report shows conclusively that a psychological factor must not be disregarded in any attempt to establish an etiology and to describe a pathogenesis for these behavior changes. The case is the more instructive since it is one of the Neisser and not luetic infection; hence the question of organic central nervous system changes does not arise.

Case.—The patient, a Jewish male in the early twenties, entered into psychoanalytical treatment for relief from a depression of fairly long duration. Three years previous, after an illicit intercourse, he noticed a discharge from the penis. He consulted a competent genitourinary surgeon at once, and his worst fears were confirmed. He went to this consultation in a state of trepidation and anguish, and at the moment that the genitourinary specialist pronounced a positive diagnosis of acute gonorrheal urethritis the patient was overwhelmed by a depression which developed instantaneously, and whose subsequent manifestations were dejection, inability to work, and a fear of impotence. The acute urethritis lasted only a few weeks, and, so far as could be determined by the most careful clinical examination, was completely cured without complications, residuals, or sequelæ. Nevertheless, the attendant mental reaction persisted and became more severe as time went on. Indeed, in the patient there developed the following secondary mechanism. He began to indulge in a continuous series of heterosexual acts in order, as he rationalized it, to convince himself that he was not impotent. These selfimposed tests of sexual power invariably proved that the *potentia coeundi* was unimpaired. Yet the patient could not rid himself of his fear of impotence. Finally, after three years of suffering, he consulted a psychoanaly in the hope of finding relief from his symptoms.

It was a dream, reported during the treatmer which when interpreted, revealed the underlying u conscious factors that made this patient's mind vulnerable to a simple gonorrhea. The dream r as follows: *He was gazing eastward across the ocea He could see the coast of Italy where a tall buildi arose from the shore. This building was surmount by a peculiar globe. A giant approached the buildi and removed the globe.* The patient felt alarm and woke up quite distressed.

For reasons technical and specific to the ca under consideration that method of dream interpr tation was employed in which the patient is asked start associating freely to any dream element he m choose. In reply to such a request, the patient sai "Italy makes me think, of course, of Naples, whe I contracted my gonorrhea. The globe on top that building was so peculiar—it looked like t globe that is the trade mark of the Waterman fou tain pen." The next few associations followed rapid succession, the words almost leaping out of t patient's mouth: "Waterman—Wassermann—syp lis—gonorrhea." Here the patient stopped sho evidently a resistance against penetrating farther i the meaning of the dream. The patient next resum with a flow of thoughts which clearly was "talki past the point" and made no further progress w the dream. For technical reasons the analyst wi held comments and let the matter rest as it sto At the next treatment hour the patient mentioned t dream, acted as if he were ready to work it out, l failed to gain any more insight into it. The anal in no way interfered, merely waiting for the situat to develop its possibilities. At the following ho the patient said that something strange had occurr to him with reference to the dream. It had bothe him somewhat by bobbing up into his mind all d especially the giant's removing the top of the bui ing. This act made him think of cutting off penis. He then added, "This must have someth to do with the gonorrhea I contracted in Naple The analyst now no longer hesitated to supply obvious interpretation, viz., that the patient had

ted to his venereal infection as if it were a castra-
on. The patient accepted this interpretation as
rrect and immediately produced a wealth of cor-
borating material dealing with the castration theme,
ch as a memory picture of a younger brother's
rcumcision, enacted when the patient was five years
d, memories of profound childhood interests in
mestic activities such as cooking, bedmaking, and
e recollection of conscious phantasies of being a
oman by preference, etc. This additional material
early points to the interrelation between the pa-
ent's recent trauma, his childhood experiences and
npressions, and the basic infantile (unconscious)
stration wish.

Incidentally, this interpretation rendered intelli-
ble many of the subjective feelings and ideas that
e patient developed at the onset of his depression.
e said, in narrating his story, that he had felt him-
lf a cripple who could no longer walk erect, he
ared he had become an imbecile, and referred to
mself as having "strength without hands." All
ese formulations are well known unconscious cas-
ation symbols.

Since the common objection raised by critics to
validate analytic interpretations of this type is to
e effect that the interpretation was "suggested"
the analyst, it may be well to state that, excepting
formal daily word of greeting and parting, the
alyst in this case had not spoken a dozen words all
ld to the patient prior to the latter's producing
e dream and all the related associations. Neither
as the patient acquainted with the castration com-
ex and its implications. Nor can the analyst be
cused, as is frequently done, of having constructed
artificial interpretation by "selection" of associa-
ons, thus making the dream analysis an artefact
oduced by his analytical technic. For, as may be
ted, it was the patient who introduced the castra-
on theme, and who, impelled by forces unknown
himself, followed the thread against diminishing
sistance to the final understanding thereof.

For the sake of completeness one more element in
e dream, not touched upon by the patient himself,
ay be explained in the light of general psychoanaly-
cal knowledge. The patient showed no inclination
discuss the giant upon the occasion of the inter-
etation of the dream, and no explanation of this
gure was offered him lest it be premature. But
e giants in dreams is a typical father symbol. The
ream, then, corresponds to a phantasy of castration
the hands of the father. Now, children regularly
corporate the doctor into the father image. Thus
e remarkable effect of the genitourinary surgeon's
onouncement becomes understandable. The doctor
father) pronounced the patient venereally diseased
astrated). This bit of psychoanalytical recon-
ruction was substantiated by subsequent dreams
d free associations of the patient.

During the treatment the castration phantasy was
produced in the transference to the analyst in an
mistakable form. Early in the course of the analy-
s the patient spontaneously formulated the belief
at his heterosexual activities would be curtailed
the analyst. This notion was colored by a curi-
sly ambivalent emotional tone, part wish, part fear.
he patient stated he hoped that he would be able,
the analyst's behest, to rid himself of an urge as
troublesome as the sexual one forever; yet he sensed
a lurking fear lest he regret the irrevocable renun-
ciation of this pleasure source at some future time.
Now, the patient's phantasy of being restricted in the
exercise of his masculine functions by the analyst
represented in his unconscious what it would prac-
tically be equivalent to in effect, namely, a castra-
tion, while his fears were indicative of his resistances
against this phantasy. His thoughts and feelings on
the subject, as revealed by his free associations,
clearly disclosed the infantile (unconscious) castra-
tion wish as it was faithfully recast in terms of the
relation between patient and analyst, or, technically,
in the transference. The patient feared (wished)
that the analyst or doctor (father) might deprive
him of the use of his virile powers (castrate him).
Since sexual abstinence is, at times, actually imposed
by the analyst, it might be well to point out in passing
that the patient was wholly ignorant of the existence
of any such procedure in psychoanalytical technic.

It is beyond the aim and scope of this brief paper
either to discuss more than the one unconscious fac-
tor herein described, by virtue of which an acute
Neisser infection was able to operate as a serious
psychic trauma, or to indicate therapeutic results,
for, needless to say, other important mental factors
were present, and a discussion of the latter, without
which the rationale of the therapy would not be
apparent, would entail the exposition of an entire
analysis and would lengthen this article beyond prac-
tical limits. Suffice it to have demonstrated and ex-
plained, from a psychogenetic standpoint, the most
important psychological factor in the case and to
draw attention, in closing, both to the likelihood of
an analogous psychogenesis of early behavior ano-
malies in lues, independent of organic central nerv-
ous system changes, and to a common ground herein
exemplified upon which the interests of the genito-
urinary specialist and the psychoanalyst meet.

17 East Thirty-eighth Street.

Effects of the Arsenobenzol Treatment of Syphilis on Liver Function.—The investigations of H. MacCormac and E. C. Dodds (*British Medical Journal,* December 22, 1923) induce the authors to believe that the arsenical substances may be safely employed in full doses without any considerable chance of causing temporary or permanent damage to the liver tissues. The jaundice observed in syphilis, whether following arsphenamine administrations or otherwise, should be attributed to a special effect of syphilis on the liver. Two facts, however, appear to challenge the complete acceptance of such a hypothesis. The first is the well known observation that the administration of arsenic for various conditions in individuals free from any syphilitic taint may be followed by jaundice; the second is concerned with the occurrence of groups of cases of jaundice or acute yellow atrophy in seeming epidemic form among patients being treated for syphilis with arsenical compounds. In the latter case the suggestion has been made that some additional infection is present and that persons suffering from syphilis are liable to infection of this kind. Allowing full value to these observations, it can be maintained that the arsenical substances may be safely employed.

Practical Therapeutics

LARYNGEAL TUBERCULOSIS AND ITS TREATMENT*

ERNST DANZIGER, M.D.
New York
Attending Laryngologist to the Montefiore Hospital

As it is undoubtedly true that one learns by his mistakes, I, as have many others, went through all the time honored methods of treatment of this discouraging complication of pulmonary tuberculosis. But if one is honest with himself and of an analytical turn of mind, after having had the advantage of a large service such as the Montefiore Hospital offers, it becomes almost a moral duty to draw the sum total of an experience extending over almost two decades in the observation and treatment of tuberculosis of the larynx.

While the treatment of pulmonary tuberculosis can show some positive results, as the artificial pneumothorax, I regret to state that the therapeutic efforts in laryngeal tuberculosis have been rather disappointing in spite of a number of publications of optimistic tone. The only explanation of the splendid results to which some writers lay claim may, in my opinion, be based on the assumption that they do not draw a close line between inflammatory conditions complicating tuberculosis of the lung and real tuberculous lesions of the larynx. Primary tuberculosis of the larynx I have not seen once in almost twenty years of close observation. When a case seemed to be primary, either physical or skiagraphic examination of the chest showed an old healed lesion of the lung.

Laryngeal complications of pulmonary tuberculosis are not all of a tuberculous nature. We see in some cases a chronic laryngitis and tracheitis with intensely reddened mucous membranes. The degree of intensity of the inflammation is not at all in direct proportion to the degree of pulmonary involvement. In some instances of pulmonary tuberculosis there is sudden loss of voice due to paralysis of one of the vocal cords caused by a compression of the nervus recurrens by enlarged mediastinal glands or an apical pleuritis.

I also have seen cases of pachydermia laryngis and one case of rhinoscleroma. I have not observed carcinoma of the larynx as a complication, and only few cases of syphilitic manifestation in the organ in question. In some instances the nonspecific laryngitis leads to superficial loss of epithelium, which opens the way for infection by tuberculous sputum. We shall soon see superficial ulcerations involving the subepithelial tissue with infiltrations extending into the deeper layers. These ulcerations are covered with tenacious mucus, which the patient can cough up only with the greatest effort, and the removal of which with a cotton pledget is almost impossible. In case of infection by the blood or lymph current, we do not find ulcerations but submucous infiltrations which extend deeply into the submucous area and even into the intrinsic muscles and cartilages and joints of the larynx.

*Read before the Yorkville Medical Society of New York, October, 1922.

Another form of tuberculous lesions in the larynx is the tuberculomata, which clinically can scarcely be differentiated from ordinary papillomata. The seat of predilection is the plica interarytenoids, but they also occur on the vocal cords. The prognosis depends on the type and location of the lesion.

Tuberculomata, the socalled cockscomb situated on the plica interarytenoids, I have seen disappear spontaneously with an improvement in the pulmonary tuberculosis and the general condition. In other instances I have seen tuberculomata remain stationary for years. If they grow very large or are situated so as to prevent coaptation of the vocal cords, they produce hoarseness or even dyspnea, but never pain.

Pronounced infiltration of the epiglottis, especially if there is a perichondritis present with ulceration, causes agonizing pain in swallowing, the pain radiating into the ear of the affected side, as in the act of swallowing the tongue pulls the epiglottis backward to cover the aperture of the larynx. As the patient under such circumstances is not able to swallow sufficient nourishment, his resistance suffers and he succumbs rapidly to the disease. Such cases rarely last longer than three to six months.

Infiltration of the posterior part of the larynx, the plica, the arytenoid cartilages, false or true vocal cords, or ulcerations in the same region, while they make the prognosis unfavorable do not lead so rapidly to a fatal issue. The patient becomes hoarse through infiltrations of the true vocal cords preventing proper closure during phonation, or the infiltration may become so enormous as to necessitate tracheotomy on account of threatened asphyxia.

There is one form of lesion which occurs in the form of a general armourlike thickening of the entire mucous membrane of the larynx, with few subjective symptoms.

The treatment of nonspecific inflammation of the larynx and trachea is the usual one of astringents and inhalations. These cases do not yield readily to this mode of treatment, and often a change of climate will show results when weeks or months of local therapy have been without success. The treatment of tuberculous ulceration with lactic acid has not been successful in my hands; in fact, I often had the impression that it stimulated the process, produced sloughing, and did more harm than good. Tuberculin benefits local conditions by its action on the general condition of the patient. Examining a whole series of cases after injection with tuberculin, I have not seen a single case which showed a local reaction in the larynx.

Passive hyperemia, according to Bier, is not practicable in the treatment of tuberculosis of the larynx. Even if we constrict the patient's neck to such an extent that his face swells and becomes blue, the resistance of the deep neck muscles prevents the constriction of the deep cervical veins. I have not seen in a single instance a local passive congestion of the mucous membrane.

As in pulmonary tuberculosis, climatic and dietetic treatment is our mainstay. Patients with tuberculosis of the larynx do best in rather low and dry

limates, such as Arizona. An important therapeutical help is enforced silence. It is remarkable how even progressed lesions of the organ will recede or become stationary as long as the patient is willing to undergo the ordeal of absolute disuse of his voice.

Surgical treatment of tuberculosis of the larynx is in almost every case contraindicated, especially in any case where there is an active process in the lung, in the presence of fever. The same holds good for electrocautery. Only when dealing with a small circumscript lesion in an old pulmonary case, or where the pulmonary lesion has come to a point of quietude and fever has been absent for some time, may some form of surgical treatment or deep puncture with electrocautery be attempted.

Heliotherapy has recently had some very enthusiastic and optimistic advocates. I mean the treatment with Alpine light. When in Davos, Switzerland, the renowned place for the climatic cure of tuberculosis, I visited some of the best known sanatoria with the idea of finding out what they were doing with the Alpine light treatment in a place where they would not have to substitute the artificial light for the real thing. To my surprise I found it actively used only in the Dutch sanatorium, its use having been discontinued in the German sanatorium and Dr. Turban's place.

Dr. Sontjes, director of the Dutch sanatorium, says that they treat their larynx patients according to indications and use the light treatment only as an adjuvant. He believes that mild cases react favorably to treatment or even are cured, and the extensive forms with infiltrations and ulcerations are apparently not benefited. During the many years of my observation I have seen mild cases recover spontaneously. There is also the doubt in my mind whether these mild lesions were really tuberculous. Dr. Sontjes uses an apparatus constructed by himself.

The sunlight strikes a square board in front of the patient who is in a half reclining position. This board has a square opening in its centre. On each side of this opening are two little swinging doors with mirrors which the patient adjusts so that he can see his throat. Then he is taught to introduce a laryngeal speculum so that he can see his larynx. As soon as he has learned to do that, he has to hold the mirror in position and let the light shine in as long as he can control the mirror. While such treatment is almost impossible in institutional work with patients of low intelligence, it may be of advantage to patients in private practice with proper cooperation. But if we come to light treatment of cases on the sea level, we have to substitute some form of artificial light for the Alpine light. In Vienna I visited the heliotherapeutic department of Professor Hajek's clinic, where I had an interview with Dr. Witte who is in charge of that department. He had the same experience as the man in Davos—mild lesions get better, more severe ones do not. He uses an apparatus similar to Dr. Sontjes, but uses also the direct method of throwing the light into the larynx while doing suspension laryngoscopy. He also treats only mild cases, as suspension laryngoscopy is distinctly contraindicated as soon as there is a deep involvement of the larynx structures. The trauma of suspending the weight of the body on the inflamed and infiltrated tissues would outweigh any possible benefit to be derived from the heliotherapy. The treatment of tuberculosis of the larynx should not be aggressive, only palliative.

For the intense pain of swallowing, we should give the patient before his meals an emulsion of orthoform or propaesin as advocated by Freudenthal.

Menthol	10.0
Olei amgygd. dulc.	30.0
Vitelli ovi	Two yolks
Orthoform	12.5
Aqu. dest. q. s. ad	100.0

This is administered by means of the Yankauer dropper, which the patient is taught to introduce himself. He gets enough relief by this procedure to be able to take enough food to prevent starvation.

Another method of relieving the pain in swallowing is the injection of the superior laryngeal nerve with alcohol. Only a small proportion of the cases are successful, but in these instances the patient might be relieved for days or weeks. The following is the technic as described by Hoffman:

One and one half c. c. of ninety-five per cent. alcohol is injected into the fossa above the thyroid cartilage about half an inch outward from the highest point of the cartilage. The needle is introduced straight downward or slightly toward the medium line. If you strike the nerve a sticking pain is felt in the ear on the same side through irradiation of the auricular branch of the vagus nerve. Any surgical operation in the nose, pharynx, or larynx ought to be avoided, as I have seen repeatedly tuberculosis of the larynx following such procedure.

As we find in the vault of the pharynx in pulmonary tuberculosis very frequently tubercle bacilli, it can be easily understood why the infection can be carried by open bloodvessels to the neighboring larynx.

While this thesis is of only negative value, it teaches one point: not to endanger your patients' chances by doing too much. Or as the Nestor of our medical fraternity once said: *Ne nocere.*

285 Central Park West.

Ventriculography as an Aid in the Localization of Intracranial Tumors.—Adams A. McConnell (*British Medical Journal,* November 3, 1923) states that in his hands, ventriculography when properly performed has given definite and accurate information regarding the position of intracranial tumors. It must never replace clinical methods, but in certain cases it is indispensable. It is not without danger, but no treatment or lack of treatment is without danger in cases of intracranial tumor. Ventriculography is not simple, it is not to be attempted without a sound knowledge of the anatomy and physiology of the central nervous system. It requires much patience and minute attention to details. Above all, it must be performed with what appears extreme slowness. If a competent neurologist cannot localize an intracranial tumor by clinical means, it is reasonable to put the possibilities—and the risks—of this method before the patient. It is also reasonable to assume that the risks will diminish with increasing experience. The alternative to accurate localization is death.

Historical Medicine

The Antiquity of Gout

LLEWELLYN JONES LLEWELLYN, M.B.

London

Member of the Conference (Medical Research Council, London) on Arthritis and Allied Rheumatoid Conditions; late Senior Physician Royal Mineral Water Hospital, Bath.

Gout—that riddle of the ages—upon which so many physicians, from time immemorial, have expended their dialectic skill. I say time immemorial, for gout is, in truth, hoary with age, as ancient as civilization. It enjoys the distinction of being the first joint disorder to achieve clinical individuality.

Thus, three centuries before the birth of Christ, the pioneer priest physician Hippocrates enunciated his classical aphorisms on gout to his disciples in the Temple Asclepion, in the Island of Kos. Many of his dicta, too, have stood the corroding test of time, and one cannot but admire the vividness and accuracy with which the Father of Medicine depicted the salient features of gout. Nor was gout, even in those days, merely a matter of academic interest, for apart from the writings of physicians, the works of philosophers, historians, and satirists abounded with allusions to the disease.

Thus Cicero, writing before the dawn of the Christian Era, describes the excruciating tortures of gout —*Doloribus podagrae cruciari*—and the peculiar burning character of its pains—*cum arderet doloribus podagrae.*

In the first century again, we find Ovid the Augustan poet lamenting that his gouty chalk stones defied the art of medicine, while in the second century, Lucian poured out his contempt on the various quack nostrums vaunted as cures for gout, even in those remote ages.

Nor can we marvel at the widespread interest evoked when we recall that the ravages of gout in the Roman Empire in the third century, were such that the Emperor Diocletian, by an edict, exempted from the public burdens those severely crippled thereby.

I cannot help thinking that we have here a blatant illustration of political pandering to national vice. For Diocletian can hardly have been ignorant of the fact that two centuries before, Pliny and Seneca deplored the growing prevalence of gout. They recalled that it was almost unknown in the early more virile days of the Empire, and roundly and prophetically declared that it was a sign of their impending decadence, clearly attributable, as it was, to riotous living and debauchery. Surely, in this we have a striking proof that gout is the nemesis that o'ertakes those addicted to luxurious habits and dietetic excesses. But if this be true, it is fortunately, no less certain that nations, like individuals, when they fall on hard times, lose their gout.

Thus the Arabs, at the zenith of their medieval empire, were extremely prone to gout, but their descendants, the hardy nomads of the desert, are almost exempt from its ravages. Is it not significant, too, that during the recent great war, the incidence of gout in this country diminished rapidly?

As to the antiquity of gout in our own country, we know that it was extremely prevalent in the Anglo-Saxon period. A matter for regret, but not for astonishment, when we recall their coarse gargantuan feasts, washed down with huge draughts of ale, and sack and the well spiced Hippocras.

In short, from these remote times onwards, through the Middle Ages, up to the present day, an almost continuous series of historical records testify that not only has gout always been with us, but also that its clinical characters throughout the ages have remained unaltered, conforming always to the primitive type.

But, in justice to our forefathers, it must, I think, be granted that the frequency of gout in ancient times was probably overestimated. This conclusion is, I think, inevitable, when we recall that it was not until the middle of the seventeenth century that even acute rheumatism was differentiated from gout. Can it be questioned, too, that a large percentage of the cases of gout, in those bygone times, consisted of undifferentiated infective forms of arthritis? Syphilis and gonorrhea must have existed then, as now, and their specific forms of arthritis. Surely, too, they, like ourselves, must have suffered with pyorrhea and other infective disorders which we know to be frequently followed by arthritis.

In short, the differentiation of arthritic disorders was then hardly in its infancy, and it is in the light of this disability that we must appraise the clearly extravagant claims of the older physicians as to the prevalence of gout in their day.

GOUT THE HONORABLE DISEASE

As I have just said, it is certain that the frequency of the occurrence of gout, in former days, was overestimated. This because, owing to ignorance, it became, so to speak, the dumping ground for a whole medley of joint disorders which we now know to be wholly distinct from gout. But apart from the meagre knowledge of the older physicians, another factor that contributed to swell the number of victims to gout was the absurd delusion that to have the gout was highly creditable, and a mark of good breeding. We may well smile at our forefathers, but I can assure you that the absurd delusion is not wholly dissipated even today. We all recall the story of the old Scottish gentlewoman who would never allow that any but people of family could have bona fide gout. If one of her servants perchance aspired to this privilege, she scouted the very idea. "Na na," said she, "it is only my father and Lord Gallowa', that hae the regular gout!"

As to the origin of this mistaken ambition, I cannot help thinking that it was the outcome partly of the fact that gout was a malady chiefly met with in

ersons of exalted station—among the great and ealthy—and alas, often those of intellectual disnction. Statesmen, warriors, literary men, and oets loom large among its victims. Lord Burleigh uffered greatly therefrom and good Queen Bess n that account, always bade him sit in her presence, nd was wont to say, "My Lord, we make much of ou, not for your bad legs, but for your good head." The great statesman, Pitt, suffered atrociously ith gout, and Horace Walpole was particularly anoyed that he developed it. As he plaintively writes, If either of my father or mother had had it, I nould not dislike it so much. I am herald enough o approve it, if descended genealogical, but it is n absolute upstart in me, what is more provoking had trusted in my great abstinence for keeping it rom me. But thus it is."

In truth, some of the most illustrious of our coun-rymen were martyrs to gout—Milton, Dryden, Linaeus, Newton and Fielding, and I may add that hysicians, too, enjoyed no immunity. The great Harvey was tormented with gout, and was wont to reat it after the most heroic fashion. He used to o with bare legs on to the leads of his house, sometmes in midwinter, and then proceeded to soak them n a pail of icy water, until he nearly collapsed from old. (Caleb Hillier Parry.)

Again, John Hunter was similarly plagued, not to nention the distinguished Dr. Sydenham who, however, consoled himself with the pithy reflection that out destroys more wise men than fools.

In short, the frequency with which gout figures n the life history of some of the ablest men in all ges, is most remarkable. Hence, I fear, the complacency with which lesser men often without good eason, affect to have the gout!

Imitation is the sincerest form of flattery: and ow potent, the power of fashion! The desire to ape, not only the tone and manners of the higher orders of society, but their very infirmities. This ignoble ype of flattery reached its climax in the case of courtiers, and provoked the scorn of Samuel Butler who, n his *Hudibras,* tells us that courtiers were accusomed to wear garnitures on the toes of their shoes, o justify their pretensions to the gout. Here, I may remind you, that Louis XIV of France, once suffered from fistula in ano, and to gratify the insatiable vanity of this monarch many of his courtiers pretended that they were similarly afflicted.

But lamentable to relate, men who claimed to be intellectuals were not immune from this vice. Thus, Plato was somewhat deformed, one of his shoulders being slightly higher than its fellow, and his disciples, in admiration, padded their shoulders in imitation of their master's deformity. Again, Aristotle suffered with an impediment in his speech, and his pupils forthwith started to lisp.

In the light of these facts, one can scarcely marvel that even today, patients claim to have the gout, and are by no means pleased when they are contradicted. Women, especially, hold tenaciously thereto; even those of austere type, clinging to the taint handed down to them from some far off ancestor, whose "superfluity of naughtiness," as St. Paul termed it, was a byword among his generation.

But, apart from the fact that to have the gout was to be in the fashion, there was a widespread fallacy that gout conferred immunity from all other disorders, and moreover, favored longevity. I may remind you that a certain Archbishop Shelldon is said, not only to have longed for gout, but actually to have offered £1,000 to any one who would procure him this blessing. For he regarded gout as "the only remedy for the distress in his head."

Indeed, in the early part of last century, we find Dr. Heberden deploring the fact that people are "neither ashamed nor afraid of it, but solace themselves with the hope that they one day shall have the gout. Or if they have already suffered it, impute all their other ailments not to having too much gout, but to wanting more." Naturally, in view of this widespread delusion that, if you had the gout, it would drive away all other evils, and ensure you long life, it is hardly a matter for surprise that misguided persons deliberately courted a fit of the gout, by resorting to excess and intemperance.

But alas, the unpleasant fact remains, that gout does not ensure freedom from other maladies, and if you present yourself for insurance, you will find that your premium, instead of being lower, is distinctly weighted, if you are predisposed to gout.

Tempora mutantur, nos et mutamur in illis.

Leonardo da Vinci, the Anatomist and Physiologist

CHARLES A. CLOUTING, M.D.
London

Leonardo da Vinci was the most wonderful man hat Florence, that city of wonderful men, ever proluced. In the first place, he was the most illustrious llegitimate ever born, although the roll of those born nder the bar sinister contains some remarkable ames. Leonardo was also the most versatile genius he world has seen. While his fame rests on his aintings, he excelled in almost all branches of cience, and forestalled some of the most startling nventions of modern times. His work as a man f science was essentially that of the individual. He vorked out problems by himself. He sketched a machine by which a man could walk under water, but said that he would not divulge it "because of the evil nature of men, for they would use it for murder at sea by sinking ships together with those in them." He described the invention of a taxicab and breech loading cannon, and was engaged by the notorious but able Cesar Borgia as his Master of Ordnance. Of his mechanical investigations the most astonishing were directed to the solution of the problem of flight, and he left behind a series of sketches illustrating the gyrations of birds in the air. He was acquainted, too, with the idea of the parachute.

Leonardo's knowledge of medical science was deep and accurate. He made experiments in biology and his observations thereon were astounding in their prescience.

His most notable work, however, was done in the realms of anatomy and physiology. He dissected numerous bodies with infinite care, and for many organs his drawings and records were closer to facts than any anatomists were able to turn out until the nineteenth century. His anatomical drawings are among the most treasured possessions of the King's Library at Windsor Castle, and others of his manuscripts relating to science are at Holkham Hall, Norfolk, England.

In the department of physiology, he was most brilliant, and anticipated in some respects the discoveries of the immortal William Harvey. It is said that Leonardo da Vinci was within an ace of discovering the circulation of the blood.

Undoubtedly, as stated previously, da Vinci was the most versatile genius in the history of the world. He excelled in everything he took up, but had he not been so versatile, he might have been the greatest painter of any age. He painted a few masterpieces, when his insatiable craving for knowledge impelled him to seek new fields. However, he possessed the scientific mind even more perhaps than the artistic bent, and it also appears that the study of what were then considered mysteries of the human body attracted him more powerfully than any other study.

Leonardo was born perhaps before his time, but was the pioneer in many branches of knowledge, and after all, the time and place in which he lived was better suited to the individualistic deep thinker than the restless noisy age in which we live. Florence, too, when the Medici ruled, was the Mecca of artists, who received greater honor and respect than in any place before or since. In the realms of intellect, Leonardo da Vinci was a prince among his peers, but he was also endowed with the solitary spirit of true genius.

Contributors to the Science of Medicine

ANTONIO SCARPA

In his volumes of charming biographical sketches entitled *Disciples of Æsculapius*, Dr. Benjamin Ward Richardson, F.R.S., writes: "In my early days as a teacher, during an examination in physiology on the subject of the fluid of the membranous labyrinth of the ear, I asked a student the question, 'Who was Scarpa?' And the reply came as fast as it could be spoken, to the amusement of the whole class: 'The man who invented the triangle.'" Thus so many famous men are known and distinguished by a name or a word, sometimes characterizing them truly, sometimes not; yet this designation clings to them through the ages, although their other contributions to life may have been much greater and more valuable.

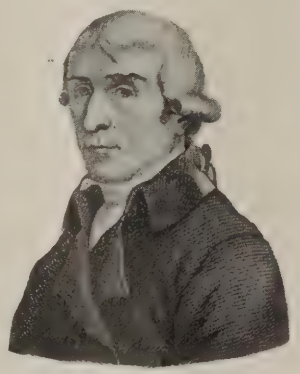
Scarpa described more clearly than any one of his predecessors the triangle formed by the sartorius muscle and the adductor longus, and suggested the operation of tying the femoral artery at the apex of the triangle, and so, to all anatomical students. he is known as the man of Scarpa's space or Scarpa's triangle, and in spite of the fact that this was by no means his best or his most practical work.

The date of Scarpa's birth is variously given, the year ranging from 1748 to 1752; the place was Motta, a little village in the Austrian Tyrol. His parents were poor tradespeople, but an uncle, having become a priest and educated himself at the monastery, undertook to transmit his learning to young Antonio and succeeded in interesting and inspiring the boy to such a degree that he prepared himself, in spite of great poverty and other almost insurmountable obstacles, for the University so that he was ready at the age of fourteen to enter the School of Medicine at Padua. At twenty-two, he was elected professor of anatomy at the University of Modena, and at thirty-seven he was appointed to the chair of anatomy and clinical and operative surgery at the University of Pavia, at that time probably the world's centre for the scientific study of anatomy. This university is considered by some authorities to be the oldest in Italy, tracing its origin from the time of the great Charlemagne. Scarpa's classes here sometimes included as many as two thousand students at a time.

Pavia was also one of the great centres of that time for culture, learning and art, and the abode and visiting place of many wealthy and prominent people from many nations, so the young surgeon was able shortly to build up for himself a large and lucrative practice, and to make a name for himself that was known in all the capitals of Europe. He amassed a large fortune, for his early days of poverty and a natural thriftiness, called by his enemies penuriousness, had taught him the value of money and how to save it.

Scarpa was a connoisseur and collector of art treasures, with which he furnished his residence, a veritable palace, at Pavia, and many of which may now be seen in the museum in that city. He was one of those few great men who have attained wealth, friends, fame, and a brilliant reputation and have lived to see and enjoy them. He died at the age of eighty-two, worn out from five years of torture from renal calculus and chronic inflammation of the bladder. During the latter part of his life, his sight failed so that he became almost blind. He never married, most of his interest and affection seeming to have been centred in a pupil, Jacopi, to whom he played the part of father until the former's early death, which affected Scarpa so greatly that he temporarily gave up his teaching. Another person who influenced greatly his life and career was the great Morgagni. Scarpa was so ardent and capable

a student at Pavia that, during his second year at the university, he was appointed assistant demonstrator under Morgagni, then very old and almost blind but still in possession of his remarkable intellectual faculties. The old man soon made the youth his secretary, and the latter, through reading to his master from contemporary medical literature and recording his case histories, received an invaluable training. Morgagni personally conferred upon him his medical degree from Pavia University, and recommended him as his successor there. The great pathologist later died in the arms of this beloved pupil and friend.



ANTONIO SCARPA

Scarpa worked also with Calza, professor of midwifery, and fashioned for him many of his wax models; he made a tour of Europe with Volta of electrical renown. He was a friend also of Alexander Brambilla, surgeon to Joseph II, Emperor of Austria, and the personal physician to the Emperor Napoleon I. Francis I decorated him, and Napoleon conferred upon him the Cross of the Legion of Honor and the Order of the Iron Cross. He had also many prominent friends among the faculties of the universities of Paris, London, and the cities of Austria and Germany, where he did some of his work.

He was a prolific writer and the author of many essays, memoirs and longer works on anatomy, surgery and physiology. He was also so accomplished an artist that he made the originals of all the illustrations for his works, some of which are considered even now the best anatomical plates ever published. Most of his books were written during his vacations, at his country house, for he was never idle. He had a wide acquaintance with all literature, both ancient and modern, and spoke several languages. He preferred the Latin language as a medium for conveying his scientific opinions and always delivered his lectures in it.

Scarpa was so eloquent and erudite, as well as able and successful as a practitioner, that his presence and services were widely sought, both at home and abroad, by scientific societies as well as individuals. Once when the Empress of Francis I was suffering from a malignant disease, although Italy and Austria were at war, Scarpa was sent for by the Emperor to treat his wife, and, under a flag of truce and with a military escort, crossed the Tyrol, cured the Empress, and returned under the same conditions to Italy.

Among the things besides his "triangle" for which Scarpa is known in medicine were his discovery that muscular structure is also supplied with nerves; the invention of many operations on the eye, descriptions of which have been translated into English by Dr. James Briggs; and he laid the foundation for much of our present knowledge of aneurysms, neurology and hernia. He himself considered his work on the last subject as his masterpiece. He discovered also the membranous labyrinth, and the nasopalatine nerve, was the first to regard arteriosclerosis as a lesion of the inner coats of the arteries, and the originator of iridodialysis. He made a model shoe for club foot which is still used by orthopedists. Many authorities consider his greatest work to be the magnificent *Tabulæ Neurologicæ*, giving the first proper delineation of the nerves of the heart.

Scarpa's career illustrates how much can be done with slight clinical material properly used. In his time, the population of Pavia did not exceed twenty thousand, and the hospital where he worked had only three hundred beds divided among half a dozen clinics.

The portraits that have come down to us show a face the characteristic of which is firm resolution and determination coupled with unusual refinement. Some of the incidents of his life reveal this independence of opinion and spirit. When in 1796 the Transpaduan Republic was proclaimed, Scarpa refused to take the oath of allegiance to the new government, and so was deprived of all his university appointments. He took the matter calmly and practically in that it enabled him to give more time to scientific and literary work. When Napoleon heard of his dismissal, he was very angry that politics should have been allowed to interfere with the work of so great a scientist, and ordered his immediate reinstatement.

Scarpa has been described as tall and well built, with a square but powerful frame, lithe and enduring; his eyes were large and black and as piercing as an eagle's—"microscopic, telescopic, from which nothing in the range of medical vision could escape"; nose finely modelled and strongly set; lips firm and compressed. His speech was animated and fluent and his voice sonorous. He had a vigorous constitution and was an ardent lover of nature and outdoor sports and occupations. This was probably one of the secrets of his vigorous and healthy old age. He was reserved almost to austerity in manner, and simple, straightforward, and direct in all his dealings and relationships. Richardson writes: "It were difficult to imagine any sick person doubting Scarpa. Look at him and live—or die."

Social Aspects of Cancer.—As long ago as 1792, John Howard, a London physician, in a letter addressed to the governing body of the Middlesex Hospital, gave the principal points of the social aspect of cancer. Considering the date of this document, it may be interesting to quote Howard's conception of the aims of his work: 1. To give permanent aid to the sick, who, by reason of the seat of the disease, or its advanced stage, cannot be saved by operation or by other means; 2. to receive the sick, who, by an operation, may be relieved, improved, or cured; 3. to establish outpatients' consultations for such cases as may be advantageously treated without hospitalization; 4. to collect all observations on the sick and to permit anyone to use the scientific documents thus accumulated; 5. to try new methods of treatment, provided these present sufficient guarantees of harmlessness; 6. to undertake scientific research into the causes and nature of cancer. Is it not surprising that more than a century later our views have not changed?—*World's Health.*

Editorial Articles

ERYTHEMA OF MALARIA

Erythema is one of the frequent manifestations of malaria, being encountered in both mild and severe cases of any type, also in malaria cachexia. The eruption may develop during full evolution or in the latent phases of the infection, and with or without visceral lesions. The presence or absence in the blood of the specific organism of malaria seems to have no influence on the erythema, and this applies likewise to the type of plasmodium. This skin manifestation has been met with in cases originating in Europe, Africa, and Asia.

Malarial erythema usually occurs in successive outbreaks, at an interval of several weeks or months. As long as the malarial organism is present in the body, pink tinted maculæ may appear, scattered over the trunk and limbs. The eruption may be fleeting, lasting only a day or two, but usually it persists for two or three weeks, with total or partial retrogression, while the color of the maculæ becomes bright or dull at different times of the day. Then the eruption suddenly disappears, or it may subside progressively. In mild cases of malarial erythema, before the eruption has completely disappeared, a few extremely pale pink maculæ still being present, a new outbreak may occur, composed of numerous maculæ becoming confluent, after which the cycle recommences.

The erythema may involve the entire body, except the neck, face, and palmar surface of the hands and feet. It has, however, a predilection for certain regions, such as the sides of the thorax and abdomen, thighs, knees and elbows. It is composed of small unequal maculæ, often round or oval, but they may be irregular in shape with uneven borders. They vary in size from a pinhead to a lentil, and are never raised, invariably remaining in the macular state.

The eruption never gives rise to general symptoms. There is no pruritus and no desquamation; it simply appears, goes through its evolution, and subsides. In color, the maculæ vary from bright red to pale pink; sometimes they are a light lilac, occasionally they are violet tinged or violet in hue. In subjects with malarial melanodermia, the maculæ become impregnated with pigment, and become light yellow, brown, or even bronzed, but no matter what the tint may be they are always discrete and not always easy to detect. The maculæ are pale in the evening, and in winter this phenomenon seems to be more marked, unless the deposit of a pigment makes the lesion indelible. On the other hand, the heat of the bed or of the sun favors the development of the color, rendering it more distinct. The pressure of a finger causes the macula to become effaced; when the pressure is removed, it again becomes apparent, due to hyperemia or a simple vasodilatation.

Another phenomenon, likewise due to a disturbance of the vasomotor innervation, is the presence of Sergent's white line, which appears when the skin surface is lightly brushed over with a fingernail. In some cases of malaria the application of the entire hand on the skin will leave a white imprint, which progressively subsides. This erythema is a result of the disturbance of the vasomotor innervation due directly or indirectly to the plasmodium. Its diagnosis is easy; its morphological and topographical characters differentiate it from other eruptions, and its presence may sometimes lead to the detection of malarial infection that had been unrecognized.

DISEASE DANGERS FROM DOGS

The more important diseases which in temperate climates can be carried by dogs to man, writes Dr. Cameron in a recent issue of the *Lancet,* are tuberculosis, rabies, skin diseases, parasites, and various intestinal worms. Many dogs, especially in large towns and cities, suffer from tuberculosis. Abundant opportunity is offered for contracting it, especially in cows' milk and butchers' refuse, but the most frequent source of the disease in dogs is man. This means that the tuberculous should not be permitted to have pets, since it is the simplest thing in the world, not only for the pet dog to contract the disease, but also to hand it on to persons.

Rabies is usually confined to dogs and is spread chiefly by dogs. The tendency of the mad dog to run long distances adds greatly to the danger. The first symptom of the disease is a marked change in disposition, and, even at this stage of the malady, the saliva is infectious and the virus, penetrating a broken place in the skin or mucous membrane, can communicate the disease to man. "As a measure against this disease, all dogs in England are subject to six months' quarantine under conditions controlled by the Department of Agriculture. It is always preferable to confine a dog for observation rather than to destroy an animal suspected of rabies. The dog which started the epizoötic in England is supposed to have been smuggled in by air."

The dog can have four kinds of ringworm and three kinds of mange, two of the latter being transmissible to human beings. The two kinds of lice that

live on dogs cannot live on man, but several species of dog fleas live also on humans. The most important nematode occurring in the dog is Tozascaris limbata, the eggs of which are easily ingested by humans who are careless in handling dogs. Another type of round worm often causes rabiform fits in puppies. Several types of flukes found in dogs occur also in man.

Two of the tapeworms found in dogs, the double pored tapeworm and the minute Echinococcus granulosis, are most dangerous to human beings. The former grows to a length of twelve to fourteen inches and passes its cystic stage in the biting louse and in two species of fleas. A single insect may contain fifty larvæ. If an infected insect is swallowed by dog or man, the tapeworm develops to its full size in about a month. As many as 238 have been found in a single host. The most dangerous of animal parasites of the dog is the echinococcus, the cause of hyatid cysts. The minute larva makes its way through the intestinal walls into the blood and it carried to a suitable organ, frequently the liver, where it develops into the bladder worm. The cyst is exceedingly dangerous as it may attain the size of a child's head. "The infection in man can come only from the dog—from badly washed vegetables, from the hands, from the dog's mouth, etc. The dog in turn can be infected only through carelessness in the disposal of infected meat by uninformed persons. This danger is probably the greatest that is run by man from the dog as the symptoms in the infected animal are at the most vague and often absent; and there is no Pasteur treatment available. . . .

"The remedy is to treat the dog as a dog and not as a human being. He must be kept free of parasites, and all ailing animals in the household where tuberculosis is suspected should be sent to be tested."

THE HONOR OF THE GOUT

Gout is one of the most ancient diseases of civilization; indeed, according to Ewart, it is as old as civilization itself. On the other hand, while definite and unequivocal evidence has been found that osteoarthritis existed in Egypt in 1300 B. C., no hint is given in the writings of Greek and Roman medical men that the disease was recognized as a distinct entity, as a joint disorder, different from others of the same class. As a matter of fact, it seems unlikely that gout was known to any extent among the notoriously hard working Egyptians or the Romans of the Republic or the Greeks in the days when "Spartan" was a byword for abstinence and sparse living.

Gout, at any rate in its acute form, is largely the outcome of luxurious living, consequently it may almost be taken as a signal that the nation is approaching the stage of decadence. In the Rome of the later empire or in Greece of the same or an earlier period, when the people were permeated with riotous living and saturated by sensuality, gout was rampant. In England, the disease was known in the earliest times. The Anglo Saxons were gross living people, addicted to the pleasures of the table—great meat eaters and heavy drinkers of beer and mead. Gout is indeed an ancient disease in Great Britain, where two or three hundred years ago, *Morbus Dominorum,* as the name implies, was an honorable distinction. It was esteemed as a selfevident mark of good breeding. Certain it is that many great men were martyrs to this honorable disease, not only in Great Britain, but in Europe and America as well. The most celebrated example was Pitt, the first Earl of Chatham, who when suffering from one of his periodical severe attacks, rose from a sick bed and died almost in the House of Commons itself, when thundering against the war of independence.

A curious fallacy has always existed in respect to this disease, namely, that it confers upon its sufferers freedom from other diseases and insures long life. As Dr. Llewellyn points out in his work on gout, a certain Philander Misaurus, issued a brochure entitled *The Honour of the Gout,* purporting to be written "right in the heat of a violent paroxysm," and was published for the common good (1775). "Bless us," he says, "that any man should wish to be rid of the gout; for want of which he may become obnoxious to fevers and headache, be blinded in his understanding, lose the best of his health, and the security of his life." And forthwith in his zeal for the common good, he gives us the following implication: "Blessed Gout, most desirable Gout, Sovereign Antidote of Murdering Maladies, powerful corrector of Intemperance, Deign to visit me with thy purging Fires, and throw off the Tophous Injury which I may have suffered by Wine and Wit, Too hard for the virtue of a Devotee upon a Holy Festival. But fail not thy humble suppliant, who needs thy Friendly help to keep his tottering Tenement in order; Fail him not, every Vernal and Autumnal Equinox."

Gout is regarded as a jealous occupant of the human tenement, brooking no interference by other disease. This belief, albeit unwarranted by facts, has died hard; really it is not yet completely dead. The truth is that so far from being a disease tending to long life and conferring immunity, it cripples and devitalizes the system, rendering it open to attacks from other maladies and shortening existence. But, and this point should be emphasized, although one may be descended from gouty forbears, and therefore susceptible to the disease, it does not follow that the honor of the gout will be conferred upon him.

The Nemesis of those predisposed to the affection came about only by selfindulgence. Abstinence and plain living will hold the disease in abeyance. The severe forms of gout, seldom met with nowadays, occurred in those who indulged too freely in the pleasures of the table, and especially in those who drank too much ale and heavy wines such as port. Some hundred years ago men drank two and three and even four bottles of port wine nightly. It was fashionable to do so, and the consequence was that acute gout was fairly common. It was unknown, however, among men who lived temperately and earned their daily bread by the sweat of their brow. The moral of this is: Avoid the "Honour of the Gout" by living temperately and abstemiously, if of a gouty predisposition.

WOMEN IN MEDICINE

On October 12, 1874, the London School of Medicine for Women came into existence, and it may be said that the Royal Free Hospital, to which it is attached, is the only hospital in Great Britain in which all the students and the majority of the staff are of the female sex. In October, then, this medical school will celebrate its fiftieth jubilee. The celebration, which is to be on a wide scale and of a dignified character, takes the fact into full account that the opening of the medical profession to women marked the beginning of all the notable advances that have come since. At that time the doors of all the professions in Great Britain were closed to women. Hence it has been decided that the central feature of the celebrations shall be a service of thanksgiving at St. Paul's Cathedral. There will also be a festival dinner on October 24th, for which the Corporation of the City of London is granting the favor of the use of the Guildhall. At this dinner the company will include men and women representative of politics, of all the great social work of the city itself, and of art and literature. It is intended, moreover, that the speakers shall be of special importance and brilliancy. Several other functions of a less dazzling kind will take place, and in fact, every effort will be put forth to render the commemoration of the first women's medical school in Great Britain fully worthy of so epoch making an event.

It will be quite in place here to sketch briefly some of the incidents connected with the history of women in medicine in Great Britain. It is interesting to recall that the first British woman doctor, and if a mistake is not being made, the first woman to take a degree of medicine in America, Dr. Elizabeth Blackwell, succeeded in obtaining in 1858 the degree of M.D. from the University of Geneva. Therefore, the honor of granting medical degrees to women really belongs to this country. Doctor Blackwell, on account of having an American medical degree, was able to lay claim to a place on the British Medical Register and practised both in London and in this country. In 1865 Miss Garrett, afterwards better known as Dr. Garrett Anderson, passed all the examinations in medicine of the Society of Apothecaries, then the only medical body which granted medical licenses on qualifications to women, but still failed to receive official recognition.

Four years later Miss Jex Blake, Mrs. Thorne, Miss Chaplin, Miss Pechey, and Mrs. deLacy Evans made a determined onslaught on the University of Edinburgh, but had to endure numerous rebuffs and disappointments, and even litigation, ere they reached their goal. In the meantime, a sufficient number of women had offered themselves to teach to demonstrate that the time had come for a women's school of medicine to be established. A sum of £6,500 was forthcoming, and many famous medical men of half a century ago, among them Professor Huxley, were ready to give ungrudging support and thus the project was launched under favorable auspices. During the first three years some thirty-four students entered the school, not knowing how or when their degrees would be won, until in 1877 the King's and Queen's College, Dublin, decided to admit women to final examinations, provided that they held already the degrees of Berne or Zurich. At about the same time Dr. Septimus Buss had brought a resolution before Convocation of the University of London in favor of admitting women to its medical examinations. At the present time women in Great Britain have no difficulty in becoming medically qualified, and most of the medical schools admit them as students.

The Royal Free Hospital is full to overflowing; at Charing Cross Hospital there are as many women as men students; and in all the medical schools and hospitals to which women are admitted, more women have asked for admission than there is room for. So far as ability and aptitude for medical and surgical work are concerned, women are quite equal to men. Indeed, their average ability is said to be higher than the average ability of men students, while they are more persevering. They shine in examinations, and it is whispered that men are inclined to be somewhat jealous of the manner in which girl students assimilate medical and surgical knowledge. They fill staff and house appointments at hospitals wherever open to them with the greatest credit and are peculiarly well fitted for research work and for inspectorship of schools and factories.

It has been contended that women are not suitable for general practice, as the life is too hard and wear-

ing, but when the work that women did in the war at the front and at home is considered, this argument will hardly admit of close analysis. At the front in the Balkans, the Scottish Women's Surgical Unit, under Dr. Elsie Inglis, did strenuous work, while one of its members, Dr. Louise McIlroy, who is now director of the Obstetrical and Gynecological Unit at the London Medical School and Royal Free Hospital, amply demonstrated her skill and knowledge and her ability to undergo the hardest work under trying conditions, by becoming after leaving the Scottish Women's Unit, the head of a hospital in Salonika, and during the first year of the armistice being in charge of a hospital in Constantinople. Of course, however, there are numerous examples of women doctors during the war undergoing vicissitudes and hardships, both at the front and at home.

In the cursory consideration of women in medicine, the progress made by American women has not been alluded to. British women are especially referred to in this respect, because the coming commemoration of the fiftieth anniversary of the first women's medical school in Great Britain is made the text upon which this article is based. There is no country in the world in which women in medicine have made more progress and have so fully demonstrated their ability to hold their own in competition with men than in the United States. Of course, as in all professions and trades, in this age of acute competition, it is a case of the fittest that survive, and the law of nature is applicable to both sexes in medicine as in any other human endeavor. The celebrations soon to take place in London are a conspicuous proof of the survival powers of women in medicine. In some branches of medicine and surgery, women excel; in other branches men are in the front; but there is room for all, and especially at the top.

HEALTH AND MENTALITY

That great scientist and ruthless iconoclast, Karl Pearson, has recently been studying the relationship of health to psychical and physical characteristics of children and has given us some interesting and valuable conclusions as to his findings. The four thousand children studied were from four to nineteen years of age and in middle class English schools, and the data were evidently handled in a superior fashion.

As to the age of the school child and his health, Pearson finds that there is little connection. That *on the average* the health of the child of four will not be sensibly modified as he grows older. There has probably been much exaggeration about the idea that children grow stronger with age."

As to certain traits: conscientiousness, selfconsciousness, shyness, and temper (sullen, quick, or goodnatured), he finds these do not change much with age or education. In habits of quietness or noisiness or in their degrees of vivacity, boys become quieter and girls grow somewhat noisier with age. He believes this is due to physiological changes taking place in the teens.

In handwriting he finds little or no change in that of the boy, but, on the average, a sensible drop in the quality of girls' handwritings occurs with the coming of puberty and the emotional changes it involves. The relation of athletic qualities to intelligence he finds significantly marked. It is the intelligent rather than the slow or dull who exhibit athletic prowess.

With regard to the charge of evil influence of games on English public life, he says that it is real enough but that it has been brought against the wrong people. The athletic boy is, on the average, healthier than the boy who is not good at games, he is fairly conscientious, if a somewhat assertive and undoubtedly noisy child. "He is in several respects better, in none worse, than the average child. The stress should be laid on the folly of those nations and sections of nations who spend their leisure not in training muscle and mind to cooperate, but in looking on while others perform."

He does not find that any bodily measures show much relationship to health and he thinks "even the importance of *actual* weight—as distinguished from changes in weight—has been much overestimated as a factor of health. . . .

"Nature selects for physique and she selects for intelligence, but her selection in the past has been rather an alternative, than a combined selection. The eugenist desires a selection which will combine both.

"Taking an all round view of the matter, it is surprising how small is the relationship of general health to the psychical characters. It would seem that far too much weight has been attributed to the health factor in dealing with mental characteristics. I believe a large part of this exaggerated view of health has been due to its study in public elementary schools. In such schools apparent health may not represent hereditary health; that may be modified by defective environment, by want of medical care and even deficiency of food. . . . It is the parent, not the teacher, who provides the metal: all the teacher can do is to give it an edge and temper it.

"Beneath the ceaseless flow of life the feeble mind of man catches now and again some glimpse of deep biological purpose in the universe; he sees it mid the shifting vortices of the flood only too obscurely. Nature does not work through man but on man;

and she works not with his ineffectual tools, but with her own allpowerful machinery. She made, by variation, by inheritance, and by ruthless extermination, the moderately amiable, the moderately intelligent man of today out of an untamed and mordacious precursor. Is it not blind audacity for man to claim that by aid of his puny, if undoubtedly useful, little polishing tools, such as education and medicine, he can achieve as much in a school life as Nature with her omnipotent mechanism has taken in all probability a million years to produce? If man would throw himself into sympathy with Nature's purpose, let him appreciate to the full extent the potency of her methods, and endeavor as his slender strength may permit to use her tools."

NEW MEDICAL PERIODICALS

The worldwide interest of the medical profession in the subject of cancer and its causation and prevention has been recently evinced in the publication of another new periodical, the *Journal of Cancer,* a quarterly issued in Dublin by the Cancer Research Fund of Ireland. The first number was published in January of this year, and contains articles by Pilger, in charge of the electromedical department of the Dublin Skin and Cancer Hospital; Crofton, lecturer on pathology at University College, Dublin; and Wintz and Rumpf, of the Erlangen Clinic, Bavaria. An editorial in the journal states that it is the intention of the editors to make it "as far as possible a complete and accurate record of all the most recent developments of cancer in regard to its cause, treatment, and cure." Contributions from specialists in all parts of the world are invited.

Another new publication, which issued its first number in April, is the *American Journal of Physical Therapy,* of which Dr. Charles R. Wiley is editor. The subjects covered by the articles in this periodical will include hydrotherapy, radiotherapy, electrotherapy, heliotherapy, radium therapy and thermotherapy. An editorial note states that "this journal is primarily for the benefit of the man in the field, who, in the last resort, is the man that wages and wins the war against disease and death. . . . The all-important need of the practitioner is to be kept in constant touch with the leading workers in all portions of the field, and furnished with practically up to the minute, ready to use information which he can immediately translate into his practice. This is the sort of material which we propose to disseminate through our reading pages. We intend to make them a clearing house of all the best that is being thought out and accomplished by the leaders in physical therapy throughout the world which has a genuine working value for the practitioners of medicine." The journal is a monthly published in Chicago by the Professional Press.

The *Review of Clinical Stomatology* is the title of a third magazine which has recently begun publication. The editors are Alfred Asgis, D.D.S., of New York City; Dr. George W. McKenzie, of Philadelphia; Dr. William G. Shemeley, also of Philadelphia, and Walter B. Veazie, Ph.D., of the University of Colorado. The journal is to be issued monthly as a supplement to the *Journal of Ophthalmology, Otology and Laryngology.* The purpose is, as stated in an Apologia by the editor in chief, "to give some small impetus to the movement to make stomatology and dentistry a specialty of medicine in fact as well as in name, as some think it to be, and to encourage the extension of graduate instruction which will impart to the mouth surgeon the technic and knowledge which has been acquired by general surgery."

CANADIAN SOCIAL HYGIENE REPORT

The final report of the medical committee of the Canadian Social Hygiene Council on the Standardization of the Diagnosis and Treatment of Venereal Diseases has recently been issued by the Department of Public Health at Ottawa. The intention is to place a copy in the hands of every practising physician in the country. This report, a pamphlet of more than twenty pages, covers the following phases of the venereal disease problem: Medical research and laboratory questions, including licensing of men doing Wassermann tests and standardization of methods of making these tests; diagnostic tests in syphilis by demonstration of treponema palladium; significance of Wassermann reaction; negative Wassermann reaction and precautionary measures; Wassermann tests in connection with the treatment of syphilis, especially as an evidence of cure; treatment of syphilis and relative value of arsenicals and nonarsenicals; eligibility of marriage; minimum requirements of treatment; treatment of syphilis, including early primary cases and dark field; Wassermann positive, secondary, tertiary, and latent syphilis; hereditary syphilis; early preventive treatment; gonorrhœa; treatment of acute urethritis; complications of gonorrhea in the male; chronic gonorrhea; pelvic gonorrhea; gonorrhea in the adult female and treatment; and gonorrhea in children.

The report recommends that all laboratories, including those of universities, doing Wassermann tests, be licensed by and under the supervision of the Provincial Board of Health, and urges that private, university, hospital, municipal, and provincial laboratories, in the use of these tests, adopt recognized methods so as to approach uniform results for the purposes of comparative study.

The report is an important document, well worthy the attention and study of physicians and health officers in the United States.

News Items

History of Science Society.—A new organization is being formed to encourage the study of the history of science, and to afford a common meeting ground for scientists, historians, and philosophers. David Eugene Smith of New York is acting as corresponding secretary.

Association Meetings.—The American Psychoanalytic Society held its annual meeting at the Hotel Traymore, Atlantic City, on June 3rd. A feature of the meeting was a paper by Dr. Otto Rank, of Vienna.

The American Psychopathological Association will meet in Philadelphia, June 7th, at the College of Physicians.

The American Therapeutic Society will meet in Toronto, Canada, June 6th and 7th, at the Academy of Medicine.

Rockefeller Institute Director.—Dr. Francis Gilman Blake, of the Yale Medical School, has been elected to the Board of Scientific Directors of the Rockefeller Institute, to fill the vacancy created by the death of Dr. Hermann M. Biggs.

Medical Films.—The Society for Cinematographic Instruction in Medicine and Surgery, with headquarters in New York, announces that after two years intensive experimentation, it is ready to produce films for the medical, surgical, dental, drug, and allied professions.

National Committee for Prevention of Blindness.—At the recent annual meeting the following officers were elected for the coming year: President, Hon. William Fellowes Morgan, New York; vice-president, Dr. F. Park Lewis, Buffalo; and secretary, Miss Winifred Hathaway, New York.

Mental Hygiene Legislation Committee.—An advisory committee on legislation has been appointed for 1924 by the executive committee of the National Committee for Mental Hygiene, largely as a result of frequent requests for a model commitment law. Dr. L. Vernon Briggs, of Boston, is the chairman.

Doctor Simmons Retires.—Dr. George Henry Simmons, now in his seventy-third year, for twenty-five years editor of the *Journal of the American Medical Association*, has requested to be retired. A banquet is to be held in his honor at the Congress Hotel, Chicago, on June 9th, during the meetings of the Association.

American Gastroenterological Association.—At the recent annual meeting the following officers have been elected to serve for the ensuing year: President, Dr. Arthur F. Chase, New York; vice-presidents, Dr. Charles G. Lucas, Louisville, and Dr. Frank Smithies, Chicago; secretary, Dr. John Bryant, Boston; and treasurer, Dr. Clement R. Jones, Pittsburgh.

Dental Research at Mellon Institute.—Dr. C. C. Vogt is the incumbent of the new industrial fellowship of the Mellon Institute, established by E. R. Squibb and Sons of New York, and devoted to the study of the chemistry of preventive dentistry. Doctor Vogt has been a member of the Mellon Institute for the past ten years. Reports of the studies will be published from time to time.

X Ray Infections.—Dr. Frederick H. Baetjer, professor of roentgenology at Johns Hopkins Medical School, has recently undergone his fiftieth operation to remove infections caused by x ray burns. Doctor Baetjer has been suffering for many years from injuries received in his research work, and this last operation was performed in an attempt permanently to check the infection.

Physiotherapy.—The Beekman Street Hospital announces that it is opening a complete department of physiotherapy, in connection with its industrial accident service, to carry on work similar to that done by the Reconstruction Service in the Army, Public Health Service, and Veterans' Bureau. The department is under the supervision of Dr. Norman E. Titus.

Western Physiotherapy Society.—At the annual meeting of this association, held at Kansas City, the following officers were elected: President, Dr. L. A. Marty, Kansas City; first vice-president, Dr. R. W. Fouts, Omaha; second vice-president, Dr. W. P. Patterson, Springfield, Mo.; secretary, Dr. Charles Wood Fassett, Kansas City; treasurer, Dr. W. P. Grymes, Kansas City; registrar, Dr. H. A. Spilman, Ottumwa, Ia.

Distinguished Foreign Visitors.—Prof. John Sendziak, of Warsaw, Poland, read a paper on Problems in Otology and What Poland Is Doing Toward Their Solution, as guest at the last meeting of the Section on Otology of the Academy of Medicine.

Dr. Nils H. Heitman, chief tuberculosis officer of the Norwegian Government, and Dr. Germund Woigin, professor of hygiene at the University of Upsala, Sweden, are in this country as guests of the Rockefeller Foundation, to study public health work.

Dr. Vera Scantlebury, chief physician of the Victorian Baby Health Centre, of Australia, is in New York studying health centres.

Scholarships for Postgraduate Study.—Applications may be made to the New York Postgraduate Medical School and Hospital for scholarships for graduate study in medicine on the Oliver-Rea Foundation.

Framingham Demonstration.—Dr. Ralph V. Matson, of Portland, Oregon, has been invited to report on the Framingham Tuberculosis Demonstration at the International Health Conference at Wombley, England.

Heroism Medal.—Dr. Harry M. Archer, honorary medical officer to the New York Fire Department, is to receive the James Gordon Bennett medal for extraordinary heroism, the highest honor the Fire Department can bestow. The award was won through the rescue of two laborers caught under tons of debris, after ten hours' duty.

Dr. Dutton to Establish a Research Laboratory.—Dr. W. Forest Dutton, medical director of the Hospitals of the Graduate School of Medicine, University of Pennsylvania, has resigned. He will continue his research of the effects of certain therapeutic agents administered intravenously. He will establish a laboratory in Northwestern Texas for the investigation of the etiological factors of pernicious anemia and other blood dyscrasia.

Veterans' Bureau Appointment.—Dr. Edgar O. Crossman, Manager of District No. 1, U. S. Veterans' Bureau, has been appointed acting medical director, to succeed Dr. L. B. Rogers, who has been placed in charge of U. S. Veterans' Hospital No. 41, at New Haven, Connecticut. The new manager of District No. 1 is Col. Elon F. Tandy, who has been serving as Executive Officer of that District; he will be succeeded by Col. William E. Sullivan.

Personals.—Dr. Lewis A. Conner, of New York, was elected president of the Association of American Physicians at its recent Atlantic City meeting. Dr. Alphonse R. Dochez of New York and Dr. George F. Dick of Chicago were awarded lectureship prizes at this same meeting.

Dr. H. B. Platt, of New York, was elected treasurer of the National Tuberculosis Association, at the meeting held in Atlanta.

Dr. Charles Gordon Heyd was guest of the Ohio State Medical Society on May 15th, and presented a paper on A Review of Some Recent Work on the Surgical Physiology of the Gastrointestinal Tract, with Special Reference to Socalled Chronic Appendicitis.

Dr. E. V. Cowdry, of the Rockefeller Institute for Medical Research, has sailed for South Africa, to spend a year at the Transvaal University College in the study of the life cycle of protozoa causing diseases of domestic animals.

Civil Service Examinations.—Examinations will be held by the United States Civil Service Commission for the following positions: Physician, Grade A. neuropsychiatry, one vacancy at $3,000, four vacancies at $1,800 with quarters and subsistence at West Roxbury, and one or more vacancies at $1,800, with quarters and subsistence, at Northampton; Physician genitourinary diseases, vacancy at Boston, salary $1,500, part time; physician, orthopedic surgery and prosthetics, vacancy at New Bedford, $1,200, part time; acting assistant surgeon, röntgenology, New Haven, $3,000; medical examiner, Veterans' Bureau, Hartford, $3,500. Applications will be received up to June 30th.

The Civil Service Commission of New York State lists the following examinations: Assistant in School Medical Inspection (Physician) State Education Department, full-time, salary $3,000; Specialist for Eyes and Ears (Physician), State Education Department, full time, salary $3,750. Applications will be received up to and including June 14th.

New Clinics.—Those interested in the increase of dispensary service will be gratified to learn of many new clinics which have been opened. Some of these are here listed: North Eastern Dispensary, a clinic for malignant diseases; Fifth Avenue Hospital, clinic for hay fever and asthma; New York Hospital, a pay clinic for infants and children, the excess of costs to be financed by the James Brady Buchanan Foundation; Reconstruction Hospital, an industrial hygiene clinic under the joint auspices of the Industrial Hygiene Division of the State Department of Labor, the Reconstruction Hospital, and the College of Physicians and Surgeons; New York Hospital, clinic for nervous and mental disorders.

A GREAT HUMAN REPAIR SHOP

LEONHARD FELIX FULD, LL.M., PH.D.

New York.

HUMAN REPAIRS

We all know where to go when our watch is in need of repairs or when our automobile is broken down; but when the most wonderful piece of machinery in the world—our body—needs repairs our ignorance is appalling. After a delay which is usually long and dangerous we consult our own physician. He may be able to help us or he may refer us to a hospital. In either case our machinery will be repaired but we will in either case be left too weak to go back to work. And many of us who are in need of repairs really need neither medical nor hospital treatment. What we need is the kind of repairs every human machine needs after it leaves the hospital as cured. Where is there a repair shop for such human machinery?

A GREAT HUMAN REPAIR SHOP

There is at White Plains, the county seat of Westchester County, New York, within convenient motoring distance of New York City, the greatest human repair shop in the world, where at all times 150 men and 150 women are being restored to health and to selfsupport, without fee, charge, or expense of any kind. This great human repair shop was established through the farsighted benevolence of a great capitalist about ten years ago. This man who lived to the ripe old age of ninety-seven and accumulated many millions of dollars in the shipping business and in railroad building left his entire fortune for the establishment of this great human repair shop, which he established as a memorial to his mother. He had never been married and had lived with his sister to whom he was tenderly devoted. The methods employed in this repair shop are most effective and should be known to every one.

ADMISSION

Men and women are admitted to this repair shop on the recommendation of a hospital in the city of New York. Private physicians, large employers of labor, and others also have the privilege of recommending to the institution those in need of its benefits, but most of these men and women are recommended for admission by one of the great New York hospitals. No applicant is accepted unless it seems likely that the institution can restore that individual to selfsupporting independence. He must be a working man in the sense that he is dependent on his own labor for support, but children and housewives are also freely admitted. No patient is admitted who is suffering from any contagious ailment nor is anyone admitted who is suffering from an ailment which renders him obnoxious to others. There are no other restrictions. Each application for admission is carefully scrutinized by a competent trained nurse who is the institution's chief of admission bureau. Applicants tentatively accepted by the chief of the admission bureau are required to report in person at the New York City office of the institution where they are examined and if accepted taken at once, in a large motor ambulance carrying about forty persons, to White Plains. His first contact with the institution impresses the guest most favorably in two respects: the thoughtfulness of the management in providing each person with a light nourishing meal of peanut butter and hot cocoa before the ride begins and the remarkable courtesy, efficiency, and consideration shown by the motor bus driver in his solicitous care of those entrusted to him.

ASSIGNMENT

Upon arrival at White Plains each guest has his temperature and pulse recorded by a trained nurse, is given a meal of crackers and a cup of coffee and is assigned to a room in one of the six homelike cottages which constitute the institution. The guests leave New York at about one o'clock, arrive at White Plains at about two thirty, and are ushered into the dining room by a guide for their first meal at five o'clock. With their assignment to a permanent seat in the dining room the repair process of the institution is begun. All that preceded were only preliminaries.

DIET

The feeding of the guests at this institution is in the hands of a young woman who is the most competent dietitian I have ever known and I have selected and met professionally scores of women occupying positions of this kind, some of whom made a most favorable impression upon me. She is not only thoroughly equipped for her duties from a professional point of view, but she combines with expert professional knowledge an earnestness and zeal which serve to make the important feeding department of this institution its most successful department. The food furnished the guests is of the highest quality. It is pleasantly varied from day to day. It is admirably adapted to the varying needs of the physical and mental infirmities of the guests. It is delightfully laxative in character. It is unlimited in quantity, that is to say, each guest may have as much food as he desires of the dishes which are considered the basic dishes at each meal, such as potatoes, green vegetables, bread, coffee and the like. The food is excellently cooked. It is appetizingly and expeditiously served. These statements do not narrate what the management expects and what is sometimes found to exist. The dietitian is present in the kitchens and in the dining rooms at every meal and looks after the quality of the food, the quality of the service, and the conduct of the guests in the dining room with such zeal and efficiency that not even the slightest deviation from the ideals which have been described is permitted at any meal. It is small wonder that with such efficient feeding under such ideal conditions most of the guests gain rapidly in weight during their stay in this repair shop. Those guests who, because of erroneous methods of eating before coming to the institution, or because of false notions regarding their dietary needs, are at first slightly dissatisfied with the omission of special diets, such as an abundance of eggs or of milk or of chicken or of broth, are urged to omit one or two meals and are then tempted by the appetizing manner in which the food is prepared and served to become the greatest boosters of the dietitian who is undoubtdly this insti-

tution's most valuable asset next to the director himself. She is literally worth to each guest her weight in gold.

DAILY ROUTINE

The guests are required to be in their beds each night with their lights out at nine o'clock, when the guest designated to fulfill this function comes to each room and bids each guest a cheery good night. At six thirty each morning this guest arouses the others with a cheery good morning. From six thirty to seven thirty the guests are encouraged to walk about the spacious grounds to whet their appetite for breakfast, which is served at seven thirty and usually consists of a cereal, an egg, as much bread, butter and coffee as each guest may desire, and some prunes. At eight o'clock each guest must make his own bed in such a manner as to pass the inspection of the trained nurse. From eight to ten thirty the guests are encouraged to play games in the open air, and from ten thirty to eleven thirty they must work, as will be explained in detail later. From eleven thirty to twelve thirty is again devoted to outdoor play and recreation. Dinner consists of meat, bread and butter, tea, an abundance of vegetables and a dessert, and is served at twelve thirty. From one o'clock to two o'clock every guest must rest in bed. From two o'clock to five o'clock is again devoted to play in the open air. Supper is served at five o'clock and usually consists of vegetables, bread, butter, cocoa, a dessert and cake. From five thirty to nine o'clock is again devoted to recreation and at nine o'clock the day is ended with lights out and to bed and the same cheery good night of the guest assigned to be the host in each cottage.

DISCIPLINE

The daily routine shows that this repair shop is frankly institutional rather than homelike, and this institutionalism is one of its most efficient aids to effective repair of human ills. Irrespective of what you, in your ignorance, may wish to do, you must conform to what has been proved by experience to be best for all. From the first examination which the director gives each guest on the morning after his arrival the guest is made to feel that the director is the disciplinary fountain head of the institution, just as the recruit in the army is made to feel that the colonel is the disciplinary fountain head of the regiment. Those who refuse to obey any rule of the institution—the institution has remarkably few rules and all of its rules are most reasonable and such as a wellbred guest would unconsciously follow without any regulation—is given by the director peremptorily twenty minutes in which to leave the institution and return to the city. In the minds of the guests the director is to use their own language "The Twenty Minute Man" and every guest stands at all times in dread of getting this sentence of twenty minutes. This gives to the institution, which has guests of every nationality, every creed, every social condition, every pathological condition, almost every nervous condition, and almost every kind of temperament, the disciplinary background without which it could not function successfully.

KINDLY TREATMENT OF GUESTS

That the director is not as stern as the guests believe him to be, and that the sternness which he shows is assumed by him for disciplinary reasons and is not inherent in his nature, is apparent to the critical observer. In the first place every official of the institution, every employee of the institution, and every guest exercising authority over other guests treats each guest with the utmost consideration, kindness and courtesy. Never is a harsh word spoken to a guest by anyone under any circumstances. Not even the director speaks harshly to any guest, except that the guest to whom he gives twenty minutes in which to leave the institution, may construe this as a harsh sentence, although it is never said in the heat of passion but in the form of a command from a superior officer acting in a case requiring discipline. This uniform kindly treatment of the guests cannot be ascribed to the spontaneous efforts of the members of the staff. It must be the result of specific instructions and constant supervision by the director. This shows that his natural disposition is as kindly as his outward assumed manifestations to his guests are stern. This sternness is evidently assumed for the best interests of the institution and its guests. This view of the director's true character is confirmed by the opinion of those who knew him twenty years ago, when as a young man he was considered the most efficient hospital superintendent in the city of New York in the days before Dr. Goldwater, Dr. O'Hanlon or Dr. Winfield Smith were heard of.

WORK

Practically no medicine is given to the guests in this institution who are undergoing needed repairs. Those who have had recent operations have their wounds dressed as often as may be necessary. The trained nurse in charge of each cottage is also authorized to give the guests such medicines as may be required by each to relieve constipation, cough, and the like, but the amount of medication is negligible. The medicines of this repair shop are good food, good air, rest, recreation and work. As soon as in the opinion of the director the physical condition of the patient will permit, he is assigned to some work about the institution. For the more delicate this work may consist of basket making or cement working, or picking up papers on the lawn or lawn mowing and for stronger guests it may consist of farming or trench digging. Everyone who in the opinion of the director is physically able to do any work must work one hour a day or he is peremptorily given twenty minutes to leave the institution. The work is carefully adjusted by the director to the physical condition of each guest and is looked upon as a part of the repair treatment and not as being for the benefit of the institution. It can readily be seen that it is not for the benefit of the institution, because if the maintenance of each guest were considered worth only fourteen dollars a week the institution would be paying each guest at the rate of two dollars an hour for such work as picking up papers or weeding on the farm an hour a day, which is a prohibitive rate of pay for work of this kind. Furthermore, the guests work only five days a week instead of six or seven.

RECREATION

In addition to good air, good food, rest and work, each guest is given as part of his repair process recreation which is of two kinds—individual recrea-

tion and mass recreation. By means of frequent tournaments with prizes to the winners, and personal encouragement by the director of occupations and by guests who are qualified by experience to undertake such work, each patient is encouraged to play croquet, tennis, golf, pool, baseball, hammer throwing, bowling and similar outdoor games which have been carefully modified to meet the needs of men and women undergoing repairs. Those who are not sufficiently strong to engage in any of these games are encouraged to lie in the hammocks, to take walks about the grounds, and to stay out of doors as much as possible. The mass recreation consists of dancing and amateur entertainments every Monday, Wednesday and Friday evening from seven to eight thirty. The guests perform at these entertainments, the performances consisting of recitations, singing, dancing, magic, dialogues and such other entertainment as the guests may be capable of giving. This entertainment is volunteered by the guests under the supervision and direction of the director of occupations who is a charming entertainer of the true hostess type.

LIBRARY

The institution also has a library from which the guests may draw books for reading during idle hours. The selection of the books is not particularly good nor is the library kept in a most efficient manner. Inmate labor has been used almost exclusively in its administration and it seems that no trained librarian has been a guest at the institution in many years. On the whole the comparative inefficiency of the library is an asset of the institution. Too much reading is not good for guests in need of repairs. Being outdoors with mind free and body active is of much greater benefit to them. Furthermore the New York daily newspapers are furnished in liberal quantities to the guests each morning and each evening and these are ample facilities for all the reading which guests of this kind should be encouraged to do.

MOST EFFICIENT ORGANIZATION

When a guest who entered this institution as a frail human derelict is ready to go home fully restored to health and to gainful occupation at the end of a stay of from two weeks to a month or longer, he is prepared as the result of his experience in this repair shop to declare with fervent thanks that this is the most efficient organization with which he has ever come into contact. He has been restored from a weak helpless member of the community, dependent temporarily upon his relatives or upon charity for support, to a strong selfsupporting member of the community again able to work and to enjoy life. He thanks from the bottom of his heart John Burke for establishing at White Plains, N. Y., the Winifred Masterson Burke Relief Foundation as a memorial to his mother. He will cherish to his dying day the firm belief that this is the most useful institution in the city of New York—a repair shop where selfsupporting men and women may without one cent of cost be restored to full health and duty. God bless the soul of John Burke and of his mother, Winifred Masterson Burke, and grant long life to Dr. Frederick Brush, director of the Burke Relief Foundation.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

LONDON, *April 4, 1924.*

KING EDWARD'S HOSPITAL FUND

The annual meeting of the General Council of King Edward's Hospital Fund for London was held in London on April 1st. The report of the president was encouraging. The gap between income and expenditure, taking the London hospitals as a whole, is closing year by year. For the year 1920 which was the worst year of all, the gap, omitting all special distributions, was £353,000; for 1922 it was £174,000, and it is expected that the gap for the year 1923 will be very nearly closed. This, however, does not mean that the hospitals are in sound financial position. They will still have to keep up their income at a figure nearly two and a half times more than it was before the war and they also have constantly to adopt the latest improvements and extend their work, in order to keep pace with the needs of the patients and the developments of medical science. Then again, the figures referred to are aggregate figures, and, while there is this steady general improvement, there are a good many individual hospitals that still have deficits, and at some of these the financial position continues to give rise to anxiety. It may be said that every effort is being put forth to develop the business side of hospital administration. This has always been a weak spot in the working of the London hospitals. As the late Sir Napier Burnett pointed out in his last report of the provincial hospitals of England and Wales, the organization of the hospitals outside London has always been more economical than that of the hospitals of London itself. Tables included in the statistical report showed three things: 1. The increase of voluntary contributions in spite of postwar difficulties; 2, the growing importance of the contributions made by patients themselves either directly or through mass contributions; and 3, the varying proportion in which the aggregate surplus or deficit is divided among the different hospitals or groups of hospitals.

THE CARE OF STREET CASUALTIES

The report of the special committee of King Edward's Hospital Fund on the disposal of accident cases and cases of sudden illness occurring in London has also been issued. The following recommendations were made: 1. That King Edward's Hospital Fund, in making its annual grants, should take into consideration whether hospitals which deal with cases of accident or sudden illness occurring in streets or public places provide, first, a reasonably sufficient number of beds for such cases; second, a reasonably sufficient number of observation beds, or beds attached to the casualty department, in order to avoid, as far as possible, transfer to another institution of any patient whose condition might be likely to be prejudiced by such transfer. 2. That it be represented to the police and ambulance authorities that no institution which is not equipped for the reception and treatment of serious cases of accident or illness should be retained on the list of institutions

to which ambulance cases should be in the first instance taken, and that it be suggested to the authorities that, in drawing up the list of such institutions, the cooperation of the Ministry of Health be sought in cases of infirmaries, and of King Edward's Hospital Fund in the case of hospitals. 3. That it be represented to the Ministry of Health, in the case of street accidents or sudden illness brought to Poor Law institutions, including removals from the casualty department of a voluntary hospital, first, that no question of residence of the patient or site of the accident, or site of the transferring hospital, should be raised prior to reception and treatment; second, that no such cases should be transferred to another institution if their condition might be likely to be prejudiced by such a transfer; third, the charge for treatment of such cases should be a common metropolitan one, and not fall on the union receiving and treating such patients, and fourth, that such patients should not be subject to any disability arising out of technical pauperization as the result of their reception and treatment.

INFANTS' HOSPITAL IN VINCENT SQUARE

This, the largest infants' hospital in England, is lacking in funds necessary to carry on the work as it should be. Dr. Eric Pritchard, who was appointed director of the hospital two years ago, has been untiring in his efforts to conduct the institution on the most scientific and up to date lines and with this end in view has been earnestly endeavoring to place the hospital on a good financial basis. He has a most able coadjutor in this endeavor in the chairman of the committee of management, Sir T. J. Gomer Berry, one of the largest newspaper proprietors in the country and a master of organization. A national campaign for the saving of infant life and to secure increased support for the hospital has been inaugurated. The management committee states that at present they have "to turn away three or four applicants for admission for every one that can be taken in, a condition of affairs that can only be remedied by substantial extension of the present buildings." It may be added that the hospital, although facing the largest open space in London outside the parks, is situated on the outskirts of one of the most poverty stricken districts of London. It is well equipped for laboratory research and it goes without saying that its situation implies that it is well provided with human material for clinical investigations. As a centre for postgraduate study of infant diseases it is good in all respects and may be recommended to American medical men visiting London for postgraduate study.

REPORT ON THE ACTION OF ALCOHOL

A new report on the much discussed subject of the action of alcohol on the human system has been published by the Medical Research Council of the Ministry of Health. One dominant impression is left on the individual who reads this book, that scientific explanations aside, the effect of alcohol on the ordinary man or woman, is to remove in different degrees the normal mental control over thoughts and actions usually exercised. This one fact alone, it may be said, accounts fundamentally for most of the effects of alcohol as scientists recognize them and for most of the popular ideas and fallacies connected with its use and abuse. As is now generally known, the action of alcohol is narcotic and not stimulating. It diminishes the control of the intellect and will, the higher mental functions being the first affected. It is pointed out by the committee that its value as a fuel and as a substitute for carbohydrates in the diet is of theoretical interest rather than of practical importance. No one heavy drinker, moderate drinker or abstainer is much concerned that it possesses a small food value. The points about it that are of real value and matter to the average man and woman, are the therapeutic effects of its use in pathological conditions, its absorption in the system, the effect of moderate doses, the degree of tolerance acquired by constant use, its properties in alleviating the discomforts of intense cold, its value as a sedative, its action as a poison, its effect on respiration of the heart and on the deep temperature. All these matters are discussed without bias and unlike most books on the subject, every conclusion is supported by scientific evidence. It is not a final word. That has not been said and may never be said; at any rate, there is still much to learn. Especially is our knowledge inconclusive with regard to two aspects of the subject, namely, the effect of strictly moderate drinking on longevity, and the effect of alcohol on the digestion of food. This valuable report will be referred to on another occasion in greater detail.

SCHOOL OF HYGIENE IN LONDON

The Ministry of Health announces that a Royal Charter has been granted for the incorporation of the governing body of the London School of Hygiene and Tropical Medicine, which is to be established as the result of the donation of $2,000,000 given for that purpose by the Rockefeller Foundation. It may be recalled that in 1922 the Rockefeller Foundation offered to provide a sum of $2,000,000 towards the cost of building and equipping an Imperial and International School of Hygiene to be affiliated with London University, on the understanding that the British Government should accept the responsibility of providing for staffing and maintaining the school when established. The Government accepted the offer. The Foundation then acquired a site near Gower Street. Dr. Andrew Balfour, of tropical medicine fame, was appointed director recently. The departments of the school for which provision is to be made include, 1, applied physiology and principles of hygiene; 2, chemistry and biochemistry; 2, immunology and bacteriology; 4, medical zoology; 5, epidemiology and statistics; 6, the practice of preventive medicine, general sanitation, and administration; 7, tropical medicine and hygiene. The school will provide for the training and equipment of public health officers, and for research in the various branches of preventive medicine. Its objects have been defined by Sir George Newman as follows: 1, to make instruction of university standard available in every department of hygiene; 2, to further the practice of hygiene not only in this country, and the British Empire, but in all parts of the world.

A BOOK BY PROFESSOR MC ILROY

Dr. Louise McIlroy, who is professor of gynecology at the University of London and director of the unit of obstetrics and gynecology at the Royal Free

Hospital and Women's Medical School in Gray's Inn Road, London, has written a book concerning Constantinople, published recently in London and by Charles Scribner's Sons, New York. Dr. McIlroy served throughout the war, first with the Scottish Women's Unit under the late Dr. Elsie Inglis in Serbia, afterwards surgeon in charge of an English hospital in Solonika, and lastly in charge of a hospital in Constantinople. In *From a Balcony on the Bosphorus* she gives her impressions of Constantinople during the occupation by the Allied Armies, 1919-20. It is a fascinating and gripping description of places and people told with a freshness and a vivacity that holds the attention. Dr. McIlroy has high praise for the American relief workers among the Armenian refugees and says that the American women doctors and nurses were most devoted in their care of the children.

The book from beginning to end is of absorbing interest and shows that Dr. McIlroy, together with her high scientific attainments, possesses literary gifts of no mean order. The book is of artistic design and fittingly illustrated. It may be cordially commended to American readers as an unpretentious but enlightening record of historic days in a city in which history has been made many times.

PARIS LETTER

(From our special correspondent)

Paris, *April 20, 1924.*

PARIS MEDICAL FACULTY PAY HOMAGE TO PROFESSOR DE SCHWEINITZ OF PHILADELPHIA

At the thirty-seventh congress of the French Ophthalmological Society, to be held from May 12th to May 15th at the Faculty of Medicine of Paris, a signal tribute will be paid to the noted American oculist, Professor G. E. de Schweinitz, of the University of Pennsylvania. He will be received as the guest of honor of the congress in the large ampitheatre of the Faculty and on the evening of the same day a banquet will be given in his honor over which M. Henry de Jouvenel, Minister of Education, will preside.

Professor de Schweinitz's work in ophthalmology has won him world wide fame. During the war he was on the Surgeon-General's staff in France and a member of the editorial board for medical and surgical history of the war. He has published many noted works on diseases of the eye and his researches in ophthalmology have produced many valuable results.

HEALTH RULES

In a lecture delivered at the Sorbonne to American students, Professor Carnot laid down the following health rules, which are well worth dissemination:

1. Ventilate every room you occupy. Man is not a house animal.

2. Wear lightweight, loose and porous clothing. Arrange to remove layers of outer garments when the atmosphere becomes too warm. Expose the whole body to an air bath, and if possible a sunlight bath once daily (as when preparing the toilet in the morning).

3. Get out of doors. Get out without wraps for a few minutes several times a day if possible, for the stimulating effect.

4. When resting for recreation, be sure you are not dissipating by indulging bad habits.

5. Breathe night air at night time. Open your bedroom windows. Have no fires in bedrooms.

6. Breathe deeply one hundred times each day in an outdoor atmosphere.

7. Avoid overeating or overweight.

8. Get back to nature in the matter of foods. Remember the original food products are grains, vegetables, fruits, nuts, meat, milk, eggs and water. Man's elaboration of many of these items results in concentrated food products on the one hand and deficient food products on the other.

9. Select your diet from the natural food products mentioned in the preceding paragraphs; get a certain part fresh every day (i. e., not canned, boxed or bottled); eat the whole slowly and with cheerfulness, leaving your appetite to be your guide, provided you eat slowly. Curtail your appetite on man's alterations of foods. Drop fads and foolish notions; chew well and most dyspepsia will disappear.

10. Go to stool regularly and frequently.

11. Stand, sit and walk erect, but relax frequently. While inactive avoid draughts or cooler air currents against the back, loins and thighs. Keep the feet warm.

12. Do not allow the well known habit poisons, such as alcoholic drinks, concentrated beverages and foods, or delicacies of all types, to enter the body. Give particular attention to infections, colds and sore throat in the first stages.

13. Keep the teeth and gums healthy. Keep them clean. Eat fruits at the end of meals in order to help accomplish this. Clean the teeth before going to bed. See a dentist at least once a year.

14. The secret of great personal power is work, play, rest and sleep in moderation. Never permit a piece of work, or stress of strain of any kind, to run along without frequent interruptions in the nature of relaxations.

15. Keep serene no matter what happens.

AMERICAN MEDICAL SOCIETY OF PARIS

At the monthly meeting of the American Medical Society of Paris, Dr. Thierry de Martel, the eminent surgeon of the American Hospital, gave an interesting talk on brain tumors. He illustrated his remarks by moving pictures and showed an operation performed by means of his mechanical trephine, which possesses the curious quality of cutting through the skull without possible injury to the membranes surrounding the brain.

Dr. de Martel insisted on the necessity of early diagnosis of brain tumors, so often ignored till irremediable damage has been done to the brain tissue. He paid a glowing tribute to the work of Victor Horsley in England, and to that of Cushing and Dandy in America. He described the socalled ventriculography of Dandy, who injects air into the ventricles, so that certain brain tumors become visible to the x rays and can be more readily removed.

Among those present were: Dr. Edmund L. Gros, president; Dr. L. Fuller, treasurer; Dr. F. Desmond, secretary; Drs. Chaussegros, Rothschild, Bove and Jackson, of Paris; Dr. Roy Dunbar, of Atlanta, Ga.; Dr. Frank McCauley, Portland, Ore.; Dr. J. F. Park, New York; Dr. F. L. Anton, Los Angeles, Cal.; Dr. W. M. Kraus, New York; Dr. McAlpin, London; Dr. C. F. Gelston, San Francisco; Dr. J. J. Kaplan, New York.

STATUS OF MIDWIFE IN FRANCE

The dignified and rather prosaic proceedings of the Academy of Medicine has recently been ruffled by a discussion of the standing and prerogatives of the midwife in France. Certain phases of the subject have given rise to heated discussions that are being echoed in the medical press.

The work of the French midwife is closely allied to that of the doctor. She is supposed to confine herself to the work of accouchément, but once engaged by the family for this duty, often she extends her activities to prescribing for the mother, the child and even the members of the family, to the detriment of the family physician. But it is not this feature of her activities that is the cause of the most severe criticism. The decreasing birth rate in France has engaged the attention of the leaders of the profession and inspired a great many projects in and out of Parliament for its correction. The feeling is so strong against the practice of abortion by the regularly admitted medical man that discovery of a case under his care means not only professional ruin but the courts treat the discovery without mercy and a long term of imprisonment is his sure reward. Strange to say, however, the midwife is left practically free to pursue this nefarious practice and the incredible number of abortions that occur in France can be largely attributed to her intervention, and it is this aspect of her activities that is the subject of attack and defense before the academy.

Parliament has created prizes for large families, pensions for widows with large families, and dowers for young women marrying, after they have borne three children. Professor Pinard, the former head of the department of obstetrics of the Faculty, has practically devoted his life to this subject, and is now a member of the Senate. It has been suggested to him to use his authority to secure the abolition of the midwife in France.

LETTER FROM VIENNA

(*From our own correspondent*)

VIENNA, *February 20, 1924.*

DEATHS OCCURRING IN BATHTUBS

Dr. Hermann Beer has published his experiences (he is police doctor in Döbling, near Vienna), regarding deaths which occur in bathtubs in cities. The cause of death varies greatly. With elderly men it may be due to heart block, owing to the excessive heat of the water, or the room is overheated, and consequently high blood pressure occurs, which in the presence of arteriosclerosis might easily lead to unexpected fatalities. People suffering from heart disease or nephritis are subject to syncope in the bathtub not infrequently. Some cases of carbon monoxide poisonings are also recorded. These cases were either suicides, the delinquent leaving the gas tap open intentionally, or the victim had been careless in not turning off the gas. Dr. Beer, however, reports two cases in which the cause of the mishap could be ascertained. In one case the man was being suffocated by escaping gas, but was saved by his wife, who thinking that suffocation was due to the great heat, let in fresh air. The worst of such cases is that these gases have no bad smell at all, and therefore they cannot be discovered. Two cases of drowning in a bathtub occurred in the practice of Dr. Beer, both in Vienna. In both cases the victims took the bath late in the night when they were sleepy. They fell asleep in the water and were drowned. The autopsies in both cases proved that the cause of death was in fact drowning while asleep, and all other possible causes of sudden death could be excluded.

CRIMINAL USE OF NARCOTICS

In a conference of the Vienna Forensic Doctors the use of narcotics for criminal purposes, murders, robbing, thefts, etc., was discussed. In recent times, it was stated, forensic doctors were too often consulted by the criminal court to give opinions as to the action of certain narcotic poisons. Murders with poisons have come, so to speak, in vogue, and the criminals make intensive studies regarding the application of the different poisons in practice. Not long ago a criminal poisoned his victim with digitoxin. He gave him the exact lethal dose of this drug. Another used scopolamine, and afterwards applied chloroform, to make sure of being able to rob his victim at ease. The robber had been employed in a surgical ward as a servant some years ago and therefore his cleverness in using first a narcotic which is not discovered by its odor is understood. According to the Vienna criminologists the murderers use narcotics with predilection on account of making sure themselves of defending their act with the false statement that they did not want to kill their victims, but only narcotize them. Of course the judges do not accept this defense, because the poisons are employed generally in such doses that they are apt to kill not only one but even two persons. At any rate it is surprising, said the president of the society, how quickly the criminals appropriate the achievements of chemical science. On the other hand, the easy access to chloroform, ether, and cocaine, induce criminals to avail themselves of these comfortable means of killing their victims. The Society of Forensic Doctors is going to present a memorandum to the legislature requesting that certain poisons and narcotics be placed in the hands of doctors, and only in exceptional cases where the doctor finds his patient reliable enough to be given narcotics in his hands, to write on the prescription that the poison may be handed to the patient himself.

A NEW ANTIGONORRHEIC

A new antigonorrheic remedy was introduced by Dr. Klausner, of Prague, under the name of reagon. The remedy is already beyond the experimental stage and the results arrived at in all the clinics of Prague and in some ones of Vienna are most encouraging. Dr. Klausner told about his remedy at a meeting of the Medical Society as follows: "The action of reagon is based upon the antiphlogistic and antigonococcic effect of certain glycosides." The reason for this effect is yet unknown. The experiments made hitherto with other nitrate of silver preparations have demonstrated that the application of silver salts in a greater quantity is quite impossible on account of the irritating action of silver upon the mucous membranes. In opposition to this our preparation (he

invented reagon in conjunction with Professor Wichowsky) is entirely pain and irritation proof. Reagon is a glycosidegelatine compound, which contains ten times as much silver as any other silver preparation manufactured. Despite its large silver content reagon can be used in the most intensive local treatment. Dr. Klausner claims for his preparation the following advantages: it makes possible an intensive treatment, free from danger and irritation which he hopes will shorten considerably the duration of the disease.

THE TREATMENT OF DIABETES WITH PROTEINS

Dr. Gustave Singer, a professor in the Vienna University, delivered an address before the Vienna Medical Society on a new method which it is believed will reduce the sugar content of the blood and urine. He treated an eye patient of his with protein injections, and as the patient also suffered from diabetes, he also noted the behavior of the sugar content of the urine under the administration of protein. In the case of this patient the protein injections had a decidedly beneficent action on the diabetes, inasmuch as the sugar content of the urine and blood decreased, the patient gained in weight, and her general feeling was greatly improved. The good result in this case has encouraged Professor Singer to administer a protein preparation, namely caseosan, to a great number of diabetic patients. The results were still better than in the first case because these patients were treated in the hospital, where their diet and regimen was strictly controlled. The best results were achieved in cases where protein and insulin were combined; of course in severe and advanced cases only.

EXPOSING THE FAMOUS MEDIUMS OF VIENNA

A committee consisting of nine eminent neurologists and the president, Professor Wagner-Jauregg, has been sent out to ascertain the results which were allegedly arrived at in a socalled metaphysical institute, where in the past few weeks two mediums are said to have done wonderful things. These mediums were Villy and Rudi Schneider, the former fifteen and the latter seventeen years of age, both the sons of a printer. Their greatest achievement was to cause guitars and bells to send voices through the air, to the great admiration of the Vienna public. They have lifted different objects in the air, and have done other marvellous things, so that the metaphysical institute was established for them. The medical committee has just completed its task and report that the whole thing is a swindle. The two media have worked with tricks, and in the darkness manipulated with their feet, and their knees which remained free. One of the professors understood the tricks so well that after three seances could himself perform them all. The exposing of the Schneider brothers is only the one of a series carried on in all European capitals to expose the swindle of the occult and hypnotic wonders. A man named Guzik was exposed in Paris recently, and in Budapest a man named Laszlo. The Vienna professors have stated that in the past fifty years every single occultist has been exposed. The exposing of the Schneider boys has shaken the confidence of the public in occultism.

WASHINGTON LETTER

(From our own correspondent)

Washington, D. C., *April 29, 1924.*

SMALLPOX IN THE DISTRICT OF COLUMBIA

Nineteen cases of smallpox, the largest number for several months, were reported to the District Health Department for the week ended April 5th. The outbreak began several months ago, and Dr. Fowler, the District Health Officer, has in every way stressed the necessity for vaccination if the public does not wish the disease to spread further. Fortunately, the disease has been of mild type and there have been no deaths from it. Nevertheless, it is a remarkable commentary upon the intelligence of the American people that it would permit the occurrence of smallpox in the nation's capital. No possible criticism can obtain to the Health Department, and perhaps it is better to take the position that if a person wishes to have smallpox in mild form, he should be allowed the privilege of so doing. If the disease would continue to be mild in character, and if it would only attack persons who are careless or recalcitrant about vaccination, this would be all right, but unfortunately there are many innocent children and genuinely ignorant people who are apt to contract the infection, thereby causing themselves considerable trouble and the community much money.

WASHINGTON HOSPITALS TO BE RADIO EQUIPPED

As the result of a campaign which was launched in this city a short time ago by a well known New York broadcaster and his associates, the Walter Reed General Hospital, the United States Navy Hospital and the Mount Alto Hospital are to be equipped with radio at an early date. It is planned that every patient shall have a pair of head phones and will be able to listen in at any time that there is anything in the air. The funds for the purchase of the apparatus were raised by popular subscription, and already enough money has come in to equip the hospitals mentioned and to buy a central receiving set for the St. Elizabeth Hospital, the big government hospital for the insane. It is expected that this hospital will be completely fitted out, and that the scheme will be nationalized so that every hospital patient who served in the World War will be able to keep in touch by radio with what is going on in the world.

THE NECESSITY FOR A PUBLIC HEALTH MUSEUM

Just at this season of the year a special brand of tourists is pouring into Washington at the rate of about twenty-five thousand a week. It is the student tourist, and from the viewpoint of the future of the nation, it constitutes about the most important group of sightseers that come here. Great droves of boys and girls of high school and college age arrive under the chaperonage of their teachers, and are herded from shrine to shrine, there to imbibe patriotic inspiration and historical information. From the Capitol and the office buildings of the House and the Senate, even to the beautiful lawns of Mount Vernon, where just now are lavishly scattered the golden coins of dandelion, the youth of nearby states troop. They visit the National and Smithsonian Museums, the Alroyd House, the Bureau of Engrav-

ing and Printing, the Pan American Union, Continental Hall, and Arlington, where lie the nation's gloriously dead. The Army Medical Museum with its gruesome wax models of pathological specimens fascinates them; the Agricultural Department, and the various monuments to those whose claim to remembrance rests upon the prosecution of human slaughter, all attract them and they return to their schools and colleges with a new idea of the government of these United States. Yet, very few depart with any new thoughts on the protection of that most valuable asset of the nation, our public health. It is true that a few perhaps notice the Bureau of the Public Health Service, that homely building of grey stone opposite the House of Representatives office building, a sombre structure erected by Benjamin Butler as a residence, and for five months occupied by Chester A. Arthur as the White House. It is doubtful if any enter it, and if they did they would carry away no other impression save that of a rather gloomy office building of ancient structure. A few medical students may visit the Naval Hospital and the Hygienic Laboratory erected on the grounds of the Museum of Hygiene, long since unfortunately defunct. Of medical monuments there are few, the statue of Samuel D. Gross, frock coated with scalpel in hand, the beautiful monument to Hahnemann, the effigy of Benjamin Rush in knee breeches, and of course the wonderful Walter Reed General Hospital. Unfortunately, medicine and public health have very small representation in our national pantheon, and as a result the opportunity of impressing the thousands of tourists with the lessons of personal and public health is lost. It has always seemed strange that the proponents of a national department of health have not realized that a museum of hygiene in our capital would be the means of educating our citizenship as to the necessity for such a department in our government. The Public Health Service, housed in two buildings a mile apart, is discharging the national health functions, and would be the natural agency to administer a museum of this sort, and the exhibits which could be shown therein would teach a valuable lesson in the upbuilding and maintaining of a healthy people.

MEDICAL SOCIETY PLANS MODEL PRACTICE ACT

The Medical Society of the District of Columbia has launched plans to obtain a model practice act for the District by empowering the president, Dr. John D. Thomas, to appoint a committee which will draft the legislation for submission to the December session of Congress. The society is of the opinion that more stringent regulations should be invoked here to safeguard the public health. Licensing bills have been submitted by various branches of medical practice at the present session of Congress, and at a Senate subcommittee Senator Copeland, the chairman, suggested that the several interests decide on one measure that would embody the principles necessary to provide for expert diagnosis and treatment.

PROPOSED LEGISLATION

Senator Owen, who has long been identified with the movement for a strong national health, has introduced a bill, S. 3159, to establish a sanitary reserve corps for the Public Health Service. The measure is modelled after the law for the present Medical Reserve Corps of that service, and provides for the commissioning of sanitarians as Sanitarians, Senior Assistant Sanitarians, and Assistant Sanitarians, who are to receive the same pay and allowances as Surgeons, Passed Assistant Surgeons and Assistant Surgeons of the Regular Corps.

The bill, H. R. 7079, prohibiting the importation of crude opium into the United States for the purpose of manufacturing heroin, passed the House of Representatives on April 21, 1924, and was sent to the Senate for action. Congress is evidently awakening to the necessity of curbing the increasing prevalence of drug addiction, and on April 7, 1924, a resolution, H. J. R. 195, authorizing an appropriation for the participation of the United States in two international conferences for the control of the traffic in habit forming narcotic drugs, was introduced into the House of Representatives.

Senator Ball has introduced a bill, S. 1027, to regulate the practice of optometry in the District of Columbia.

On April 7, 1924, there was introduced into the House of Representatives a bill, H. R. 4122, to amend an act entitled, "An act to revive, with amendments, an act to incorporate the Medical Society of the District of Columbia," approved July 7, 1838.

HEALTH WEEK IN WASHINGTON

In preparation for this effort of the various health forces of the city, the Washington Council of Social Agencies, which is the central delegate body of approved welfare organizations, created a health committee, composed of representatives from all of the health movements and hospitals. Each day of health week had its special subject of attention, with a different person appointed as chairman for the day. A series of noonday meetings were held at Keith's Theatre, at which a person of national importance spoke. Dr. William C. Fowler, head of the health department of the District government, was the speaker on the opening day of health week, while Dr. Cary T. Grayson talked on the second day. Each address was broadcast through the local radio stations. Among other speakers listed on the program were Dr. Victor C. Vaughn, Dr. William A. White, of St. Elizabeth's Hospital; Dr. George M. Kober, Miss Grace Abbott, Dr. Edith E. Hooker and William Mather Lewis, president of George Washington University. Organizations which assisted the committee in charge of the week were the Social Hygiene Society; the Child Welfare society; the outpatient department of St. Elizabeth's Hospital; the Red Cross public health nursing service; Columbia Hospital; the Parent-Teacher Association; the Visiting Nurse Association, and the Washington Tuberculosis Association.

RESEARCH INSTITUTION DEDICATED

The new building of the National Academy of Sciences and the National Research Council was dedicated on April 28, 1924. Notable addresses were made by the Bishop of Washington and the President of the United States. The erection of the building was made possible by a $5,000,000 building and endowment donation made by the Carnegie Corporation of New York.

Book Reviews

PHYSICAL EXERCISE

Physical Exercise for Daily Use. By C. WARD CRAMPTON, M.D. Illustrated. New York and London: G. P. Putnam's Sons, The Knickerbocker Press, 1924. Pp. 303.

Dr. Crampton's foreword is to the physician. He writes: "A new field is opening for the physician. . . . You are now called to the service of making superior men, capable of living one hundred per cent. lives—the development of an increasingly better race, living more fully, happily, and efficiently, to the greater glory of God—and man. To aid this purpose, this book was written to you, your patients and health clients, to help you to prescribe exercise for them individually, accurately and with as much certainty of definite result as you expect from pharmaceutical and other therapy, to which exercise is a useful adjuvant, but not a substitute. This book is also designed to help your patients to understand your instructions and to carry them out enthusiastically and efficiently. Then again—remember that you yourself are still human; you should get for yourself the good things you give to others, especially good health in great abundance. The world needs your forward leadership." This quotation serves to illustrate the popular style in which *Physical Exercise for Daily Use* is written, so that it is significant rather for the lay person than for the physician, for whom it would be of value chiefly as an aid in the carrying out of his instructions and advice.

Abundant good health, according to Dr. Crampton, is only for those who possess three essential qualities —common sense, initiative, and will power. Common sense provides the realization that there is a kind of life that is better than mere existence. Initiative means the ability to find out by what means abundant good health may be possessed. Will power insures the carrying out of the program to success. The book opens with a description of what one hundred per cent. condition is, and the remaining chapters tell what part daily exercise, including bathing and proper breathing, plays in its attainment. The illustrations are numerous and excellent.

INTRAVENOUS MEDICATION

Intravenous Therapy. Its Application in the Modern Practice of Medicine. By WALTON FOREST DUTTON, M.D. Philadelphia: F. A. Davis Company, 1924. Pp. xi-542.

Heretofore, when one wanted to look up the subject of intravenous medication, one was compelled to resort to the various medical journals and the propaganda literature of the manufacturers in intravenous products, and much time was wasted. In this book, the author collects all the material and deals with the subjects of venesection, the various methods of blood transfusion, the introduction of saline and tonic solutions into the circulation and intravenous medication. With the increasing popularity of intravenous medication, a book of this sort has become a long felt want and almost a necessity.

The first part of the book is concerned with the general technic, which is given with the most minute detail. After outlining the history of intravenous therapy, the following subjects are taken up: venesection, saline infusions, direct and indirect methods of transfusion, their dangers and special indications, intravenous medication in pediatrics, the general technic of intravenous injection, arsphenamine and allied arsenicals and intravenous anesthesia. The second part deals with the application of intravenous therapy in the various diseases and conditions, including rare and tropical diseases, arranged in alphabetical order. The number of diseases and conditions in which intravenous therapy may be applied effectively is surprising. An appendix contains tables for making solutions, a dose table, metric equivalents, etc. In addition to the intravenous treatment, general treatment is also outlined. A bibliography is appended to each chapter. Although the book has minor faults which are easily corrected, it well deserves a welcome as a pioneer work on the subject. Intravenous therapy has come to stay and every physician should make it his duty to become proficient in its practice.

PSYCHOPATHIC CHILDREN

The Unstable Child. An Interpretation of Psychopathy As a Source of Unbalanced Behavior in Abnormal and Troublesome Children. By FLORENCE MATEER, A.M., Ph.D. New York and London: D. Appleton and Company, 1924. Pp. xii, 471.

In reading Mateer's book one feels that psychology has indeed released itself, in some directions at least, from the bonds that have shackled it. The author shows that this is so, for example, in one phase which particularly pertains to her work. This is in the matter of formal intelligence tests. And what she shows here is typical of all that she presents as related to the application of psychology to the understanding and readjustment of psychopathic children. She writes from a background of theoretical understanding of her work, but with theory fully based upon actual experience. In such experience she is alive to the complexity of the problems to be faced. The situations are fluctuating human situations presenting all the varied demands which reduce theories and methods to a subordinate place. She by no means minimizes their value. Rather she emphasizes their true value as she shows in a most practical way how indispensable they are as agents serving in more vital problems. She lays stress also upon the versatility which must be part of the equipment of the psychological worker and the patience with which such a worker must take up the problems, particularly as she faces the sensitive child. The unhurried quiet attitude, Mateer shows, is often the only one to which the psychic difficulties can respond. The writer's emphasis of this reveals how much her point of view is based on an appreciative knowledge of inner psychic mechanisms. She attests in this, as she illustrates specifically in her case reports, the value of individual analysis of the psychic situation presented. The discussion of the psychopathic child, just what is meant by the term and the relation of the child and of his psychopathic situation to the life about him, shows the same broad and sympathetic comprehension on the part of the author.

HANDWRITING AND CHARACTER

Handschrift und Charakter. Gemeinverständlicher Abriss der graphologischen Technik. Von Dr. Ludwig Klages. Fünfte bis siebente Auflage. Leipzig: Johann Ambrosius Barth, 1923. Pp. xi-254.

The author discusses the subject of handwriting from the fertile point of view of experienced psychology and psychiatry. He reveals something of the manifold expression of the psychic nature which is to be found in a man's handwriting. He lays emphasis upon the dynamic factors at work, rather than upon merely superficial factors which offer little interpretation of this or any other manifestation of the inner life. The author's general psychological discussion with which he opens the more particular study of the varieties of handwriting bears testimony to the breadth and the depth of his thought. In itself it is a stimulating psychological contribution. It is evidence of the writer's range of cultural interest which plays its part in the charm of his style. One leaves the entire work with the feeling that a rich field has been opened and cultivated, but only in part. More than the surface has been touched but greater possibilities have been disclosed which have not been entered in actual investigation. Nevertheless the work is inspiring in the direction of still deeper research. The illustrative material in the form of figures and tables, chiefly the characteristic specimens of handwriting, is suggestive of further work as it is illuminating of the work already accomplished by the author.

MAGIC

A History of Magic and Experimental Science During the First Thirteen Centuries of Our Era. By Lynn Thorndike, Ph.D., New York: The Macmillan Company, 1923. Pp. xl, 835, vi, 1036.

The large amount of material which the author has amassed in these volumes forms an important contribution to the history of human thought. It bears witness to the author's industry and erudition for it is material not readily accessible even to the student nor is it that which is easy to assimilate and reproduce. The reader is somewhat oppressed by the weight and the amount of this material where the author at times has kept himself too closely to the level of a mere compilation of matter. In his concluding chapter, however, he has given rein to his own feeling of appreciation of the task he has set himself. Reading this one is not merely fired with his interest but finds just that which one had missed earlier in the work. The warmth of this chapter gives back life to the entire subject so that this becomes what the author intended, an important record of the slow but persistent struggle of man through the early Christian centuries, and indeed in the years preceding, to free the intellectual power from the shackles of magic thinking. Thorndike makes it evident that there was more active thinking at work, even under the great weight of magic thinking, than we commonly attribute to these so-called dark ages. He presents the names and sets forth the contributions of a long succession of earnest men and at least one sincere woman. He shows how belief in magic bound them, how it spread itself in absurdities over their work. Some writers rejected certain portions of magic beliefs but retained others or created new ones. Thorndike shows how particularly difficult it was for these thinkers to throw off the notion of the stars as supernatural beings with an influence upon human lives. Only very slowly and very imperfectly through the period covered by this study did men come to anything like an experimental knowledge of facts. Some actual observation of nature is recorded but it was very incomplete and the results were obscured by the greater sway of the magic beliefs. That which was called experiment for the greater part was but a testing of some magic formula or belief upon some fact or object of nature.

Thorndike has not much more than suggested the deeper psychological significance of magic in its hold upon the human mind. He does not leave its nature entirely unnoticed, especially in his conclusion. Nor does he there fail to point out its still persistent dominance in present day communities supposedly governed by intellectual concepts. The purpose of his volumes is not so much to interpret magic as to set forth a large section of history in which it still plays a part, to reveal here the effort to attain through this mass of incorrect thinking to a more scientific grasp of facts. In this historical study Thorndike renders a further important service by setting into their relation to each other these thinkers who were preparing the way for later thought. He shows also their dependence upon thinkers of earlier periods and of other lands. No one is an isolated creator of new concepts or new methods of thought. Each one contributes something to progress, it may be only by working over some truth already discovered. All are still set about with errors which they cannot yet reject. Thus a false idealism which history has set about some of these men is corrected. So also is a new light thrown upon the accepted position of thought and investigation in this early period. These were never so hindered by external opposition as current belief would have it. The correction of such errors is part of the service of this book as it places this long period of development in its proper evolutionary setting.

DISEASES OF NOSE, THROAT, AND EAR

Applied Pathology in Diseases of the Nose, Throat, and Ear. By Joseph C. Beck, M.D., F.A.C.S. St. Louis: C. V. Mosby Company, 1924.

This profusely illustrated work reflects the author's well known wide and varied experience in clinical otolaryngology and his special studies in their underlying tissue changes. To this extent, it is a valuable and instructive volume, although there is a certain unevenness both as to quality and quantity in the treatment of different subjects. More might be said about bacteriology, serology, and immunology of diseases of the ear, nose, and throat, as pathological histology alone does not cover the ground satisfactorily. The same applies to the factor of endocrine disturbances which as a form of humoral pathology must be taken into consideration in any study of organic changes due to disease. The photomicrographs are very numerous but not all, unfortunately, very clear. The photographs of patients are better. The diagrammatic drawings are, perhaps, the best. The frontispiece in color represents the drum membrane in a hue "which never was on land or sea"—to say nothing of the human tympanic cavity.

PHYSICAL EXAMINATION FOR SURGICAL LESIONS

Exploration Clinique et Diagnostic Chirurgical. Par. FELIX LEJARS. Paris: Masson et Cie, 1924. Pp. 778.

This work in French is copiously illustrated, showing the different methods of physical examination for various surgical lesions. It is really a very valuable work, for at the present time it is the tendency of clinicians to rely too much on laboratory and x ray findings and to neglect the thorough physical examination, which is after all the main means of accurately diagnosing any surgical condition.

The author's method of palpating the spleen is distinctly original and should be of great aid. One regrets that no photomicrographs are included with the illustrations of gross specimens of tumors. The reviewer would like particularly to recommend everyone to observe his excellent illustrations of differential diagnosis between ovarian cyst and abdominal ascites.

INTRANASAL SURGERY

Intranasal Surgery. By FRED. J. PRATT, M.D., F.A.C.S., and JOHN A. PRATT, M.D., F.A.C.S. Illustrated with 195 Halftone Engravings. Philadelphia: F. A. Davis Co., 1924.

In this volume the authors aim to give a clearer, simpler, and more detailed description of the regional anatomy involved in operation on the interior of the nose and the accessible accessory sinuses, with numerous illustrations mostly from actual specimens on a large scale. In parenthesis, these drawings, the work of Miss Jean Hirsch and her assistants in the Medical Art Shop of the University of Minnesota, are worthy of all praise. The textual description of the anatomy and of the surgical procedures in question is clear, concise, and quite adequate, particularly as the many drawings take the place of a lot of words.

MEDICAL CLINICS

The Medical Clinics of North America. Chicago Number, September, 1923. Philadelphia and London: W. B. Saunders Company.

This number of the *Medical Clinics* contains twenty-one clinics by twenty-three Chicago clinicians. The range of subjects is exceedingly broad, extending from the clinic by Dr. Isaac A. Abt on the nature and treatment of collapse in infancy and childhood, to the clinic by Dr. J. P. Greenhill on the value of x ray in obstetrics. The number contains over three hundred pages of solid, worthwhile medical reading interspersed freely with more than a hundred splendid illustrations. There are excellent clinics on jaundice, hay fever and epilepsy.

SEXUAL ENCYCLOPEDIA

Handwörterbuch der Sexualwissenschaft. Herausgegeben, von MAX MARCUSE. Bonn: A. Marcus und E. Weber's Verlag, 1923.

A most useful and carefully compiled encyclopedia built around terms used in the study of the sexual life of man. The term handbook is somewhat misleading, as it is a substantial tome of about five hundred pages. It is the best work of its kind to date.

HANDBOOK OF LABORATORY TECHNIC

Handbuch der biologischen Arbeitsmethoden. Abt. IV, Teil 5, Heft 1. Untersuchung der Fonktion des Verdauungsapparates. Edited by DR. EMIL ABDERHALDEN. Berlin-Wien: Urban and Schwarzenberg, 1923.

The laboratory chemist will find in this new section of Abderhalden's extensive *Handbuch* a valuable collection of the various technical methods for the chemical analysis of saliva, feces, intestinal gases, stomach contents, etc. There has also been included some of the methods of morphological study of the intestinal contents, and even a little bacteriology. While by no means complete in its treatment of all phases of the subject presented, it will no doubt prove very useful to those engaged in clinical chemistry.

Abt. IV, Teil 8, Heft 4, is devoted to the methods of analysis of honey, artificial sweetening mixtures, and sugar products. There is but little in it that cannot be found in the larger texts on food analysis. Abt. IV, Teil 3, Heft 2, embraces methods for the physical and microscopical methods of studying the blood, including the determination of resistance, refractometry, colorimetry, sedimentation of the blood, investigation of blood platelets, and the methods of study of the hematopoietic organs. The whole forms a useful summary of the various technical methods for blood investigations, but this number, as many of the others, suffers from the enforced isolation of the contributors from practically all contact with the literature other than German.

OTOLOGY

Transactions of the American Otological Society. Vol. XVI. Part II. Fifty-sixth Annual Meeting, held in Atlantic City, N. J., 1923.

The progress of aural medicine and surgery during the past year is reflected in this report of the national society. There are practical papers on Indications for Surgical Intervention in Acute Suppuration of the Middle Ear, by Kerrison; Reports of Cases of Herpes Zoster, by Emerson, and of Meningeal Involvement, by Perkins; a review of the Pathology of Acute Otitis Media and Mastoditis, by Dickie, of Ottawa; studies of Unusual Forms of Extension, by Friedenwald; Otitic Cholesteatoma, by MacCuen Smith; Diplacusis, by Shambaugh. The sociological side of the speciality is indicated in a number of papers on instruction in otology, prevention and management of deafness, training of deaf mute children, schools for the hard of hearing, presenting an interesting symposium.

ORTHOPEDIC SURGERY

Orthopedic Surgery. By ROYAL WHITMAN, M.D., M.R.C.S., F.A.C.S. Seventh Edition. With 877 illustrations. Philadelphia and New York: Lea & Febiger, 1923. Pp. 993.

The reviewer has rarely seen a book so full of excellent illustrations as the present edition of Whitman's *Orthopedic Surgery*. There are a great number of photographs, x ray plates and diagrams, which thoroughly illustrate the points the author wishes to show. To one who is not an orthopedic surgeon, this work seems excellent. The thoroughness with which the different subjects are taken up from all points of view and the adequate bibliography would commend this book to anyone interested in orthopedics.

Medicoliterary Notes.

A recent number of the *American Review of Reviews* quotes from the *Bulletin of the French Société de Biologie* some interesting facts about the shape and position of the eyes in animals, according as to whether they hunt or are hunted. In the hunters, the eyes are in the front of the head and close together; they are deep in their sockets and protected by dorsal ridges and by the masticatory muscles. Thus, the binocular field of vision of such animals is large, while the panoramic field is limited. Hunters that lie in wait for their prey have pupils vertically elliptical; those that chase their prey have round pupils. In hunted animals, the eyes are at the sides of the head and wide apart, with shallow orbits and no protection from ridges or muscles, so that they usually protrude. Hence, their binocular field is very small or entirely lacking, but their panoramic field embraces almost the whole horizon. In the fastest runners, the pupil forms a horizontal ellipse which assists in broadening the field of vision; poor runners have round pupils. The frog, both hunter and hunted, has frontally placed eyes, but they protrude and have crosswise elliptical pupils.

Public Health in the United States: an Outline with Statistical Data, by Harry H. Moore, long associated with the U. S. Public Health Service, is one of the recent publications of Harper & Brothers. The book has an introduction by Dr. Haven Emerson.

* * * *

The new Hudson Towers Hospital Hotel has a remarkable cornerstone, which was laid on April 27th. It contains a complete set of specimens of all known disease producing bacteria; a collection of medicines regarded as specific cures for diseases; a record of diseases regarded at present as incurable, and a motion picture film showing doctors performing important operations.

* * * *

Illinois had from April 20th-26th a health promotion and safety week which included health sermons and talks in the churches and Sunday schools; a diphtheria eradication day, a dental hygiene day, a better baby conference and birth registration day, a physical examination day, a school health day, and a milk for health or better diet day.

* * * *

M. Mouquet, a member of the staff of the Paris Museum of Natural History, is the author of an interesting article, recently published in the Paris *Revue d'Histoire Naturelle Appliquée*, on the treatment of animals in medieval times. At that time, animals were supposed to have souls and a knowledge of good and evil, so were often brought into court for their misdeeds and tried, or duels were arranged between them and human beings. A story is told of a handsome dog whose master had been found murdered in the forest. The dog insisted upon fiercely attacking whenever he met him a certain man, so that the latter was suspected of having committed the murder, and sentenced to a duel with the dog. A club was named as the man's weapon, and the dog was allowed a kennel to take refuge in. The dog won.

Health News, bulletin of the New York State Health Department, reports three recent outbreaks of trichinosis in the State, with a total of nineteen cases and three deaths. The bulletin warns health officers to be on the lookout for the disease, since the physician who attended several of the cases states that he is convinced that there were many cases in Westchester County diagnosed as grippe.

* * * *

The first number of *The Endocrinist* has recently been issued. This is a small quarterly journal devoted to "comment on current endocrinology and endocrine therapy," and is edited by Dr. John J. McNulty.

* * * *

An editorial note in the *Medical Woman's Journal* states that the effects of malnutrition during the war are now being significantly reflected in the physical defects of young men who were from fourteen to twenty years of age at the time of the war, and are now presenting themselves as recruits for the Roumanian army. More than thirty-one per cent. of those who presented themselves last year for enlistment were rejected after medical inspection as physically unfit, and more than twelve thousand were rejected for the same reason during the period from January 1 to September 30, 1923.

* * * *

Recent Italian scientific journals have been describing a new "thermoaero locomotive," a simple device applicable to an ordinary locomotive with slight expense and with only slight remodelling. An internal motor, fed with oil, produces generously hot compressed air and steam, which are the motive power. It is stated that the locomotive may be stopped without stopping the motor, power for upgrades may be increased and there are no smoke, soot, nor ashes. It is estimated that traction costs on the Italian railways may by its use be reduced 70 per cent.

The British Labor Government has introduced into the House of Commons a socalled morals bill for the protection of youth. It classifies wilful destruction of an unborn child as murder; makes any woman who seduces a boy liable to two years at hard labor, *woman* being defined as a female over sixteen, and *boy* as a male under eighteen; prohibits children under sixteen from performing, singing, or being exhibited in public for gain; raises the marriage age to sixteen for both sexes (it is now fourteen for boys and twelve for girls); and restricts the sale of liquor to or by minors.

* * * *

A recent invention described by the London papers is called the pedescope. It is a Roentgen apparatus that shows the exact position of bones and muscles when a shoe is being tried on, thus not only facilitating a good fit, but also correcting foot deformities by indicating proper shoes.

* * * *

Dr. J. M. French, of Milford, Mass., has in the *American Journal of Clinical Medicine* an article on the present shortage of physicians, especially in rural districts. He quotes to confirm this fact from various sources, among them a recent report of the Committee of Medical Education made to the Philadelphia Medical Society, which states that it is variously estimated that there is in Pennsylvania only one doctor to every 400 to 700 population. Philadelphia has one to every 526 and Pittsburgh one to every 447. The proportion for the rest of the State is practically one physician to every 1,000 persons.

* * * *

Another addition to the recent list of works reconciling, or attempting to reconcile, science and religion, is a book entitled *Where Evolution and Religion Meet*, by Prof. John M. Coulter, of the department of botany of the University of Chicago, and Dr. Merle C. Coulter, assistant professor of plant genetics at the same institution. Macmillan is the publisher.

* * * *

Among the many popular errors in current belief, according to Vilhjalmar Steffansson in the *Spectator*, is that the Eskimos are not oil drinkers. "They actually consume less 'food for power,'" he writes, "than the average Scotsman or Norwegian. . . . Eskimos undoubtedly would be fond of fat—it is even possible they might drink oil—if it were true that they were more exposed to cold than the rest of us. This is the weak link in the chain." He goes on to tell us that the Eskimos are really less exposed to cold than the average American or Britisher, for they wear heavy fur clothing when out of doors, and their snow huts are so warm that in midwinter they sit in their igloos, actually steaming with persperation, which they continuously mop from their bodies with cloths. The only time the writer ever saw an Eskimo shiver was in midsummer when his clothes were worn out.

* * * *

A recent issue of the *Living Age* quotes from an article in *Young India*, the Ghandi weekly, showing how the "return-to-homespun" gospel of the Noncooperative Movement affects the daily routine of the Indian physician. Dr. Umachgi, known as one of the foremost practitioners of the city of Gadag, finishes his medical duties at twelve every day. After this, he spins and weaves for two hours. Dr. Venkat Rao, another busy physician, also devotes two hours of every day to spinning and weaving.

Abstracts from Current Literature

DERMATOLOGY

Some Observations on Striæ Distensæ.—The following conclusions are drawn by F. Bedo Hobbs (*Lancet,* September 1, 1923), in regard to striæ distensæ: 1. They are confined almost entirely to young adults between the ages of twelve and twenty-two. 2. At this age the skin is very delicate and growing rapidly and the elastic tissue fibres rupture, allowing the white fibrous tissue and overlying epidermis to stretch, thus giving rise to striæ distensæ. 3. The striæ may be associated with almost any febrile disease. 4. The distention and ultimate cleavage of the skin may be caused in healthy individuals by the rapid accumulation of fat in the subcutaneous tissues of the axillæ, thighs, etc. 5. In other cases it may be due to a simple distention following an effusion into the subcutaneous tissues. 6. Often, however, the nutrition of the skin is impaired by some constitutional disease, and the main factor in these cases is the effect of posture—the striæ occurring at the position of maximum tension.

Subcutaneous Injections of Paraffin.—R. Gersuny (*Wiener klinische Wochenschrift,* October 11, 1923) maintains that the subcutaneous injection of paraffin has not been given the consideration which it deserves, not only on account of its simplicity, but also because it has given results far superior to those obtained with operative procedures. He obtained very good results in the following conditions: saddlenose, Schlatter joint of the elbow after resection, prolapse of the rectum, flatfoot depressed scars on the neck, incontinence of urine, fistulæ and facial atrophy and hemiatrophy. Only such paraffin should be used as will not melt at fever temperature. Absolute asepsis of the paraffin used and the instruments is necessary.

Death from Eczema.—Johann v. Petheö (*Monatsschrift für Kinderheilkunde,* October, 1923) asserts that eczema may actually cause death. Its explanation probably lies in deep metabolic disturbances, which lead to the catastrophe. Pathologicoanatomical or histological investigations cannot throw any great light on the subject. It is not advisable to endeavor to cause the eczema to disappear by energetic treatment at any price, as the symptom of its disappearance previous to death is in favor of the fact that there must be some peculiar relationship between the skin and the crisis occurring within the body. The treatment of the eczema includes the production of a change in the metabolic processes, combined with local treatment, especially irradiation treatment.

Exanthem from Bathing.—Naegeli (*Schweizerische medizinische Wochenschrift,* December 6, 1923) describes a maculourticarial eruption, which is seen in persons during or after bathing during the socalled dog days (July 22d to August 22d). It usually lasts two to three days and occasionally eight to fourteen days. It appears to be infectious in origin. The noxa undoubtedly is in the water and it may be an animal plankton. Marked soiling of the water seems to have no relation to this condition.

Prognostic Significance of Exanthemata in the Late Nervous Manifestation of Syphilis.—A. Arpási (*Wiener klinische Wochenschrift,* January 3, 1924), calls attention to the fact that syphilitic eruptions are sometimes symmetrical. The appearance of symmetrical or segmental exanthemata the author considers as an indication of the presence of a central nervous affection, which is probably responsible for the development of late syphilitic manifestations, especially in the spinal cord. This also speaks in favor of an early involvement of the central nervous system.

Cause of Baldness.—According to the conception of R. O. Stein (*Wiener klinische Wochenschrift,* January 3, 1924), the theory that baldness is caused by seborrhea is not tenable, as it almost never occurs in women. He considers it rather as a purely secondary sexual character of the male who is afflicted with seborrhea. The latter disease affects both sexes and the entire scalp of the male, yet it is found practically only in males and it does not affect the entire scalp. A study of typical baldness in young men gives the impression that the entire process consists in a pushing upward and backward of the normal anterior margin of the hair. Normally, the hair line forms an arc in children and in women. After puberty the hair begins to fall out at the side of the forehead in men and this author considers a typical sex character—the socalled frontal calvities of adolescents. This frontal region is also a point of predilection for secondary sex characters in certain male mammals. The parietal region constitutes another centre of loss of hair. In eunuchoid individuals and in true eunuchs this calvities of adolescents, which constitutes the forerunner of baldness, is not observed. The bald triangles on the forehead may be seen in premature puberty and in some women with other masculine characters, especially hypertrichosis.

Toxemia of Severe Superficial Burns.—Bruce Robertson and Gladys L. Boyd (*Journal of Laboratory and Clinical Medicine,* October, 1923) used young anesthetized rabbits in the study reported, producing skin, subcutaneous tissue, and muscle burns. The transplantation of burned skin to healthy rabbits was also performed; these animals exhibited toxic symptoms in all cases within an hour of the operation. A toxin is produced in burned tissue, in larger quantities in skin burns, which circulates in the blood either in, or absorbed by, the red blood corpuscles, and which causes the symptoms seen in bad superficial burns, and in some cases death. Extract of burned skin and whole citrated blood from burn cases are toxic. Extracts of skin burned postmortem, the contents of burn blisters, and the blood serum are not toxic. There is increased protein catabolism in burns, as evidenced by the increase in the nonprotein nitrogen and urea nitrogen of the blood. The toxic substance was found to consist of two portions, one of which is thermostabile, diffusible and neurotoxic; the other is thermolabile, colloidal and necrotoxic. Chemically the toxin consists of primary and secondary proteoses. The authors could not find any evidence of the production of antibodies against the burn toxin.

SURGERY

Etiology and Prophylaxis of Clavicular Fractures Following the Veit-Smellie Maneuvre.—I. Amreich (*Wiener klinische Wochenschrift,* December 27, 1923) claims that the fractures of the clavicle following the Veit-Smellie maneuvre can be avoided. However, the Veit-Smellie maneuvre is blamed not only for the clavicular fractures following this procedure but also other clavicular fractures, which are produced even before its application during the manipulation of the arms, when the fractures are observed not at the moment of their occurrence but only later after the birth of the child. The fractures occurring as a result of the manipulation of the arms occur in an indirect manner when the clavicle receives the force during the manipulation of the arms through the scapula or through the scapula and humerus. In these cases there is a longitudinal compression of the clavicle which strikes the clavicle at its weakest point. The anatomical site of all these fractures, therefore, is the same spot on the clavicle and no conclusions as to the mechanism of its origin can be drawn from the completed pathologic end result.

Treatment of Congenital Talipes Equinovarus.—Naughton Dunn (*British Medical Journal,* December 22, 1923) states that the treatment of congenital equinovarus should be commenced at the third or fourth week. Repeated severe manipulation of the foot will be necessary to overcome the inversion and adduction of the foot. Correction of the deformity should be followed by fixation in the position of correction obtained. When the adduction and inversion of the foot have been corrected, it will usually be necessary to elongate the tendo achillis to complete the correction of the equinus deformity. Other surgical measures must be adopted unless full true correction of the deformity has been obtained by manipulation and elongation of the tendo achillis. Division of the tibialis anticus is not necessary and may lead to subsequent cavus deformity of the foot. We should insist on descent of the os calcis by division or elongation of the tendo achillis if necessary, but we should realize that prolonged dorsiflexion of the ankle may lead to nonunion of this muscle with a subsequent calcaneovavus deformity. In cases where simpler measures fail, a good permanent result may be obtained by a resection of the midtarsal and subastragaloid joints.

Physiological Principles Underlying the Treatment of Injuries and Diseases of the Articulations.—A. G. Timbrell Fisher (*Lancet*, September 15, 1923) emphasizes the need for research into the physiology of the articulations, because many stiff and deformed joints are preventable by a knowledge of physiological principles, and because such deformed joints can often be made mobile. Articular cartilage is suitable for studying the behavior of cells under varying conditions, since it contains no bloodvessels or nerves except in the perichondrium near the edge. The irregular proliferations seen in osteoarthritis are intermediate between inflammation and new growth. Bone has less vitality than the articular cartilage. In acute arthritis the part played by movement is limited, but in the chondroosseous and synovial types of chronic arthritis, respectively, complete rest is followed by sclerosis of the synovial membrane and capsule. Movement is still further impeded by the development of osteophytes at the articular margins. Secondary shortening of the tendons and other periarticular structures results and the joint slowly becomes more fixed, often in a position of gross deformity.

The affected joint should be moved to the fullest extent daily without overexertion, and every effort should be made to preserve the nutrition of the joint structures and the muscular tone. In most cases, particularly in joints of the lower extremity, the intraarticular pressure should be diminished. The etiological factor must also be sought and treated. The joint movements, besides preventing scar formation in the soft parts, cause the osteophytes to develop in such a way that there is no interference with movement.

Prognosis After Removal of Semilunar Cartilages.—In considering the prognosis special attention is given by R. J. McNeill Love (*British Medical Journal*, August 25, 1923) to the following features: 1. recurrence. 2. Pain. This is, of course a difficult symptom to assess at its true value. Many patients complain of slight or diminishing pain for an interval varying from a few weeks to two years, but unless it causes actual disabliity such pain is ignored in considering the prognosis. 3. Movement. With a relatively healthy joint, followed by absence of splinting and early movements, there seems to be no reason why movement should be restricted after operation. 4. Stability. A feeling of weakness is a common immediate after-result of meniscotomy. This is in a great measure psychical, as the patient is often accustomed to the deranged knee feeling weaker than its fellow. Encouragement soon leads to re-education and restoration of confidence; and in the majority of cases the patient soon learns to trust his knee again and appreciate its stability.

Results fall naturally into three groups: 1. Good. Where there is negligible pain, no sensation of weakness, and movements are unimpaired. 2. Fair. This includes cases in which there is slight limitation of movement or pain occurring periodically or when the limb is placed in certain positions. 3. Poor. This includes cases in which recurrence takes place or range of movement is less than a right angle; also cases in which pain is frequent or a sensation of weakness remains in the joint. Prognosis seems to depend chiefly upon two factors: the number of attacks and the age of the patient.

Recurrent or Habitual Dislocation of the Shoulder Joint.—A. S. Blundell Bankart (*British Medical Journal*, December 15, 1923), states that in some fractures, either of the anterior margin of the glenoid cavity or of the greater tuberosity of the humerus, there is an associated recurrent dislocation of the shoulder joint. Such fractures might easily be caused by the direct force which produces the initial dislocation. They must, however, be regarded as accidental, and not essential, to the recurrent dislocation. The essential feature is the detachment of the capsule from the fibrocartilaginous glenoid ligament. In the author's cases the defect was repaired by interrupted sutures of silkworm gut passed between the free edge of the capsule and the glenoid ligament. It is well to freshen the bone on the neck of the scapula, so that the glenoid ligament may adhere to it. Having repaired the joint defect, the divided subscapularis tendon is reunited, the detached portion of the coracoid process is sutured in place, and the wound is closed. After the operation the arm is kept at rest for four weeks, and then active and passive movements are begun and persisted in until the movements of the joint are normal.

Formation of Pseudarthrosis in Bone Transplants.—W. Odermatt (*Schweizersiche medizinische Wochenschrift*, January 10, 1924) states that no satisfactory theory can be established in regard to the occurrence of erosion of the transplant. We can only observe its occurrence and the conclusion can be drawn that the healthy tissues of the body have the power of gnawing through an immobilizing transplant wherever a necessary motion is disturbed. This takes the form of a coarsely mechanical articulation in the joint and of a slowly progressing longitudinal growth at the epiphyseal line. Wherever an extra-articular or intra-articular bridge of bone is inserted, even in the Albee immobilization of the vertebral column, these types of pseudarthroses have been quite frequently observed. Even though it sounds paradoxical, the author considers this process as physiological. But there are also pathological cases of this type, as in the socalled recurrent pseudarthroses, in which a cleft formation occurs at exactly the former site following a pseudarthrosis operation and in the sympathetic pseudarthrosis in the second bone of a two bone joint with pseudarthrosis of the other bone. The younger the individual the more do the tissues show this autonomous action. The lesson to be learned from this finding is that arthrodesis operations should not be undertaken before the fifteenth year.

New Operation for Certain Forms of Cleft Palate (Pickerill).—Th. Naegeli (*Schweizerische medizinische Wochenschrift*, January 10, 1924) recommends the following procedure: The posterior borders of the cleft velum are incised in such a way, for example, that on the right side the border is freshened below and externally and on the left side internally. Incisions made toward the anterior make the subsequent suture more easy. The two dissected portions are then laid transversely over the cleft, so that the right part comes anterior to the left and the freshened borders come in contact, when they are sutured with fine silk without tension. After the operation, a prosthesis is prepared by a dentist and made to consist of two parts. The anterior part is fixed to the teeth and closes the anterior cleft; the posterior part is articulated with the former by a hookshaped arrangement, which is fastened to the muscle bridge and moves with it. In this way the nasopharyngeal space is completely closed off. This operation is indicated in cases where the patient is somewhat advanced in years and where the soft parts are insufficient for the usual plastic operation and also in patients in whom the uranoplastic was unsuccessful during early years, but where there is still sufficient material for the formation of a bridge.

Treatment of Congenital Megacolon.—According to Monnier (*Schweizerische medizinische Wochenschrift*, January 10, 1924), the operative interferences for megacolon may be divided into the palliative and radical operations. The former include colopexy, coloplication, the various anastomoses and, finally, the cecostomy and appendicostomy. All of these procedures have occasionally given good results. But they are not entirely reliable because recurrences are not eliminated. Colectomy is undoubtedly the operation of choice, but the mortality is very bone ash, by the conditions under which food is obtained less than five years of age. The mortality is considerably reduced in the two stage operations (eight per cent.). The final results are excellent. If possible, the author endeavors to retain the cecum, as the proximal part of the colon has been shown to possess an important function in the process of digestion. The palliative operations are very useful, as they enable us to prepare the patient for the radical operation, inasmuch as they eliminate the danger of toxemia and enable the patient to overcome the radical operation more readily.

Transverse (Supracondylar) Fracture of the Lower End of the Humerus.—Paul Bernard Roth (*British Medical Journal*, December 22, 1923) concludes as follows: 1. The fracture occurs almost entirely in children. 2. It is the commonest fracture affecting the lower end of the humerus. 3. It can be caused by quite a trivial accident. 4. It is usually described as a separation of the lower epiphysis of the humerus, but this is a great rarity, seldom seen. 5. Many of these cases cannot be reduced by manipulation and a poor functional result follows. 6. They can, however, be reduced accurately by operation, and a perfect functional result may be obtained. 7. Operative treatment should therefore be employed far more often than it is at present.

Parathyroid Glands in Relation to Surgery.—T. P. Dunhill (*British Medical Journal,* January 5, 1924) endeavors to show that greater consideration should be given to the parathyroid glands in surgical procedures, chiefly for the purpose of warding off tetany. He believes that the parathyroids are best protected by clean dissection of the posterior borders of the thyroid gland and by ligation of the branches of the inferior thyroid artery as they enter the gland. The treatment advised for postoperative tetany includes: 1, the injection of four gm. of calcium lactate; 2, the transplantation of parathyroids from a member of the family, or an individual of the same blood group; 3, parathyroid medication.

Nature and Cause of Bone Diseases After the War.—Wilhelm Loll (*Wiener klinische Wochenschrift,* October 18, 1923) comes to the conclusion that the cause of bone diseases following the war is a qualitative change in the food, namely, a great deficiency of phosphoric acid. This view is strengthened by the findings of the constituents of the bone ash, by the conditions under which food is obtained and its nature and the results of corrective therapy.

RESPIRATORY TRACT

Treatment of Acute Pneumococcus Infections of the Respiratory Tract.—G. J. Langley (*Lancet,* January 5, 1924) establishes the following fundamental principles: 1. Pneumonia is an acute general infection. 2. Its annual deathroll is sufficiently high to merit not only careful attention but furious thinking. 3. A greater statistical knowledge is more than desirable. 4. Bacteriological investigation is not only the road to increased knowledge but also the key to treatment. 5. There is sufficient evidence to justify the statement that serum treatment should be instituted in suitably typed cases as early as possible in the disease, should be given in suitably large doses, should be repeated every eight hours, and should be persisted in. 6. Optochin in nontoxic doses merits a further trial on the grounds of experimental data. 7. Without the aid of one or both of these methods we are left with a merely expectant routine, scarcely justified in the light of such masses of evidence as modern research has placed at our disposal.

Chronic Bronchitis.—Joseph John Perkins (*British Medical Journal,* December 15, 1923) classifies the predisposing causes of chronic bronchitis as follows: 1, occupational (atmospheric pollution); 2, climatic conditions; 3, preexisting local pathological conditions, especially in the upper respiratory tract (nose and pharynx); and, 4, constitutional (often metabolic) factors. A preexisting or underlying predisposing condition can usually be found and success depends upon the treatment of such conditions. The preservation or restoration of the open air habit of life and respiratory exercises are a very essential part of the treatment. The system of respiratory exercises is divided into two courses. The first course aims, by a series of inspiratory exercises carried out in the recumbent position, at increasing the movement of the lower ribs and developing the inferior lateral region of the thorax. The lower chest is thereby expanded and the action of the lower part of the lungs is improved. When this has been attained the patient is taught, in the second part of the course, to contract the abdominal muscles and drive the diaphragm forcibly upwards. In this way the lung capacity is improved through the aeration of the lower part of the lungs.

Vaccine Therapy of Chronic Bronchitis.—J. Odery Symes (*British Medical Journal,* December 15, 1923) says that, as a rule, improvement may be assured and a cure may be frequently established by vaccine therapy in chronic bronchitis. The author's success has not been as great with stock vaccines as with autogenous vaccines. The organisms most frequently responsible for the continuation of this disease are in their order of frequency the pneumococcus, various streptococci, and the Micrococcus catarrhalis; Pfeiffer's bacillus, Friedländer's bacillus, and staphylococci are also frequently found. It is much more common to find two or three varieties of organisms in a sputum than to obtain a practically pure culture. If the sputum cannot be obtained satisfactorily a nasal swabbing way be taken. Care in the preparation of the vaccine is most important. The dose must be sufficient to excite reaction—a local reaction at the site of inoculation, and a mild general reaction. Overdosing may result in a temporary setback and shake the confidence of the patient. It is well to begin with small doses—say five million of each organism—and gradually and at short intervals to raise the dose until a reaction is obtained. The intervals between the early tentative doses should be five days, and when once reaction is established this may be lengthened to seven days. If reaction is excessive, causing distress to the patient or a rise of temperature of more than one degree, the size of the next dose should not be increased, or the interval should be prolonged to ten days. The vaccine treatment must be prolonged over a period of at least three months, although the immediate symptoms may have disappeared, the object being not merely the amelioration of the present condition but also the establishment of a high degree of resistance. Preferably a new vaccine should be prepared at least once during such a three months' course, as certain of the organisms originally present may have died out or fresh varieties may have supplanted them. In the same patient the bacteriology of successive attacks of bronchitis is seldom identical. During quiescent periods, prophylactic doses of one of the various stock vaccines used for prophylactic purposes and containing streptococci and pneumococci. Micrococcus catarrhalis and Bacillus influenzae are serviceable. Vaccine therapy certainly establishes a fairly long immunity, but absolute immunity is seldom or never secured. Failures in vaccine therapy are probably due to some error in the preparation, dose, or administration of the vaccine, and can only be eliminated by repeated bacteriological examination of the sputum and by the preparation of new vaccines of varied combinations and strengths. Failure may also be due to some constitutional disorder in the patient, which has been overlooked, such as gout, emphysema, arteriosclerosis, or cardiac insufficiency.

Climatic Treatment of Chronic Bronchitis.—E. Hyla Greves (*British Medical Journal,* December 15, 1923) asserts that climate plays an important part in the treatment of chronic bronchitis, for there is no class of patient more susceptible to changes of temperature than the bronchitic. In selecting a suitable winter climate for him it is essential to bear in mind certain important points—namely, equability of temperature, sunshine, shelter from wind (especially from the north and east), and dryness of subsoil. The sudden drop of temperature in the early morning hours often accounts for the acute exacerbations of bronchial catarrh in the aged. Overheated rooms and excessive clothing should be avoided, and aged patients should be gradually accustomed to living and sleeping in comparatively cool rooms. Underlying conditions, of which bronchitis may merely be a secondary manifestation, should be properly treated. The method of continuous inhalation of dry vapors or the various forms of vaporizers, often give definite relief, especially where associated with a tendency to bronchial spasm. Definite relief is also obtained from dry cupping over the bases of the lungs in acute or subacute exacerbations of the catarrh, especially when the bases become engorged and dyspnea and cyanosis become pronounced and the right side of the heart embarrassed.

Chronic Bronchitis in Relation to Nose and Throat Infections.—G. Seccombe Hett (*British Medical Journal,* December 15, 1923) emphasizes the following points: 1. Many if not the majority of cases of chronic bronchitis have their source of infection in the upper respiratory tract and are descending infections. 2. In all cases of chronic bronchitis the nose and throat should be examined from this point of view. 3. Pathological conditions of the nose and throat should be treated. 4. Special attention should be directed to the treatment of nasal obstruction, nasal sepsis, and nasal sinus infections.

Pneumonia and Its Complications.—Walter Broadbent (*Lancet,* January 5, 1924) states that in the treatment of pneumonia it is most important that the patient should be kept as quiet as possible both when nursing procedures are being carried out and during physical examination by the doctor in order to prevent autoinoculation from movement. As to specific treatment, a vaccine, if of the right type of pneumococcus and the correct combination of germs, may be useful, if given early in the disease; but it is not safe in the deeply toxic cases with low temperatures, as the negative phase may be too much for the patient. In delayed resolution, when the physical signs are not clearing a week after the subsidence of the disease, autogenous vaccines are of great assistance, also after operation for empyema they hasten the cure. In some cases antipneumococcus serum has given some good results. Medicinally, aspirin is

undoubtedly valuable, but the doses should not be too large. Quinine, given with aspirin, is also helpful, and this especially in postinfluenzal cases. The creosote and iodide mixture has given good results but the patients dislike it. Ipecac and iodide may be useful in loosening expectoration. Oxygen should always be kept ready. As a sedative at night Dover's powder is one of the best. In cases of intense poisoning Warburg's tincture is valuable given by mouth or rectum, as, besides being a bactericide, it is a strong stimulant. It must be given in alcoholic solution, since water precipitates the resins and destroys its efficacy. Hyperpyrexia should be treated with ice, sponging or packing, and by large doses of Warburg's tincture. It is important to watch the heart. In the early stages of lobar pneumonia, if there are signs of overdistention of the right heart, six leeches over the site of the pneumonia will have a good effect. If the pulse rate is above 100, digitalis should be given regularly, but not in large doses, and if up to 120 hypodermic injections of strophanthin should be given. Camphor hypodermically is also useful.

Treatment of Asthma with Combined Peptone and Vaccine.—John Veitch (*British Medical Journal,* January 5, 1924) used three different strengths of solution: 1. Five c. c. of five per cent. solution equals 0.25 gm. peptone plus 235 million organisms mixed catarrhal vaccine. 2. Five c. c. of ten per cent. solution equals 0.5 gm. peptone plus 940 million organisms mixed catarrhal vaccine. 3. Ten c. c. of ten per cent. solution equals one gm. peptone plus 1880 million organisms mixed catarrhal vaccine. The injections were given every seven days: for the first four weeks half a tube of solution 1 a week, for the second four weeks half a tube solution 2, and so on, increasing the strength of dose. The injections were given intramuscularly in the socalled painless area just below the anterior superior spine of the ilium. The following points were noted: Generally the results were quite good.

NEUROLOGY

Massage as a Therapeutic Measure in Psychomotor Excitement.—L. Stanojevic (*Wiener klinische Wochenschrift,* December 27, 1923) comes to the conclusion that both dry massage of the entire body musculature as well as massage and effleurage in the warm bath are excellent therapeutic measures in the strictest sense of the word in psychomotor conditions of excitement. They are a vast therapeutic improvement over the remedies used for this purpose heretofore. This kind of physical therapy is contraindicated in organic diseases of cardiac muscle, severe cerebral arteriosclerosis, conditions of amentia and in epilepsy with severe spastic attacks.

Nerve Centres: Their Constitution and Significance.—P. T. Herring (*British Medical Journal,* October 27, 1923) states that sensation and reflex action are closely bound up together. Even visceral reflexes may be productive of sensation. Alterations in the heart beat, palpitation, respiratory disturbances, vasoconstriction and vasodilatation give rise to subjective phenomena. Irritability, exhaustion and depression are of common occurrence in ill health. The fatigue of a synapse renders that synapse more resistant to the passage of a nerve impulse, and fatigue of the afferent pathways should be a negation. But fatigue and the sensations met with in ill health are positive sensations and not mere negations. They are, as a rule, general and not localized to any particular part. Their cause is unknown, but must be sought for in some alteration in the afferent nerve impulses affecting the conscious state.

Treatment of Migraine by Calcium Lactate.—A. Douglas Bigland (*British Medical Journal,* December 15, 1923) has obtained excellent results in the treatment of migraine with calcium lactate. At the first sign of an oncoming attack, as evidenced by the ocular aura, thirty grains of calcium lactate should be taken immediately. The patient should always have the tablets of calcium lactate with him. The tablets should always be fresh. Calcium lactate does not cure migraine, but it does abort the attack and frequently it prevents the occurrence of the headache and vomiting and does not keep the patient from his work.

Treatment of Encephalitis Lethargica.—In a review of the therapeutic experiments on encephalitis lethargica, Hans Hoff (*Wiener klinische Wochenschrift,* December 20, 1923) draws the following conclusions: 1. The intravenous administration of urotropin does not appear to produce any improvement in the disease. 2. The intravenous use of large amounts of iodine in the form of a fifty per cent. solution of sodium iodide or of Pregl's solution does show improvement, especially in the myoclonic forms, but it cannot prevent the transition of the disease into the chronic stage. 3. Marked improvement in the forms of this disease associated with meningeal symptoms was observed following injections of staphylococci and meningococci. Injections of iodine and typhoid bacilli improve the results, particularly in acute cases, but the results were poor in the chronic cases. Similar results are obtained with intravenous injections of Pregl's solution and typhoid bacilli. The Besredka vaccine was always used intravenously. 5. With the use of typhoid injections alone marked improvement was always observed in the lethargic forms of the disease. 6. In a number of acute cases vaccineurin was injected intravenously—with fairly good results. This remedy may also prevent recurrences. This treatment was useless in the chronic cases. 7. With the aid of therapeutic malarial inoculations it was possible to improve about one fourth of the cases treated in which there were sequelæ of the encephalitis; among these there were also a number of cases of Parkinsonism. However, the improvement was not very marked. 8. As a rule the Parkinsonism and the other sequelæ of the encephalitis appeared to be improved by injections of sodium cacodylate, but even with this remedy the improvement was not very striking. 9. It is evident that acute encephalitis is quite amenable to treatment.

Experimental Studies on Encephalitis.—Fritz Silberstein (*Wiener klinische Wochenschrift,* January 10, 1924) found that healthy dogs may be the carriers of encephalitis. In two cases, healthy dogs developing encephalitis, in which Eck's fistulæ were established after the feeding of meat, acted as carriers to rabbits. By means of immunization of rabbits carried out for a long time it is possible to produce a relatively highly virulicide antiencephalitis serum. As a result of these experiments on the pathogenesis of encephalitis, the author advances the following theory: As a result of disturbances in the intermediary metabolism—especially the loss of function or injury of the liver—the immunizing and protective mechanism of the central nervous system may be injured to such an extent that a saprophytic organism, hitherto dormant in the nasopharyngeal space, may produce a fatal infection. Inasmuch as not only the identity of the herpetic and encephalitic viruses is probably established but also as healthy persons may be the carriers of the encephalitic and herpetis viruses, respectively, the inference that such an injury may be responsible for the enigmatical relationship between herpes and encephalitis seems plausible.

The Parkinsonian Syndrome in Lethargic Encephalitis: A Pathological Posture.—Ivy Mackenzie (*Lancet,* December 29, 1923) states that the outstanding features of organic behavior in the Parkinsonian syndrome are the attitude of the patient, the muscular rigidity, and the impediment of voluntary movement especially of a rotatory character. In the absence of evidence of involvement of the corticospinal tracts attention is attracted to the complementary proprioceptive system. Examination of the vestibular apparatus shows that in a proportion of cases there is evidence of interference with the normal processes of somatic equilibration.

Treatment of General Paralysis by Infection with Malaria.—W. McAlister (*British Medical Journal,* October 20, 1923) reports a series of twelve cases, in which he inoculated the patients with blood drawn by syringe from a patient at the height of a malarial paroxysm. Each patient received a subcutaneous injection of approximately two c.c. of infected blood. The injections were made in the loose skin just below the angle of the scapula. When the needle was inserted the subcutaneous tissues were probed in all directions to a distance of about an inch and a half so as to diffuse the plasmodium and promote absorption as rapidly as possible. The patients were then allowed to resume their normal mode of life. The subsequent treatment was as follows: The infection was allowed to run its course unimpeded for any number of paroxysms up to twelve (average ten). To arrest the infection, quinine hydrochloride was given in doses of ten grains every four hours for three days, and thereafter five grains were given thrice daily for fourteen days. The temperature in every case began to subside immediately after the administration of the quinine and became stabilized by the fourth day.

Medicolegal Notes.

AUTHORITY FOR TREATMENT GIVEN—NECESSITY FOR FREQUENT EXAMINATIONS.

In a malpractice case where there was reputable authority shown by the testimony of expert witnesses for the treatment given, the Washington Supreme Court holds, Miles v. Hoffman, 221 Pac. 316, that the physician could not be held negligent in following that treatment.

In this case the patient lived in the country, some miles from the doctor's office, and was attended by untrained nurses, conditions which the court considered, "the doctor knew or should have assumed, and notwithstanding the seriousness of the injury and the results which medical men look for and seek to avoid in such cases, there was no evidence of careful instructions or warning to the nurses which, as the jury might readily find, should have been given, and in the absence of such instruction, the infrequency of the doctor's visits, his failure to take the temperature of the patient, and the like, of which there was some evidence, were such as warranted the jury in finding that respondent could, if he had been more diligent in these respects, have detected the presence of infection, and perhaps that the synovial sac had been penetrated, long before he did. Although the proper treatment was administered in the beginning, yet there may have been negligence in not giving proper instruction, or making frequent and sufficient examinations to determine the necessity of a change of treatment."

This view, the court said, would have necessitated a reversal of the judgment for the defendant appealed from, had there been proof from which the jury might reasonably have inferred that the final results were caused wholly or in part by such want of care; but no such proof was found in the record, and the judgment was affirmed.

CHILD MURDER—PROOF OF BIRTH ALIVE.

In a prosecution for murdering a child at birth the Tennessee Supreme Court holds, Morgan v. State, 256 S. W. 433, quotes the definition of murder as contained in the Tennessee Code as the killing of "any reasonable creature in being," which is the common-law definition as given by Coke and Blackstone, and holds that, in such a case, in order to become a "reasonable creature in being," a child must be born alive. "It cannot be the subject of a homicide until it has an existence independent of its mother. It is usually said that the umbilical cord must have been severed, and an independent circulation established. Ordinarily, if the child has breathed, this would show independent life. But this test is not infallible. Sometimes infants breathe before they are fully delivered, and sometimes they do not breathe for quite a perceptible period after they are delivered. Generally, however, if respiration is established, that also establishes an independent circulation and independent existence."

The court also pointed out that it is not necessary that the injuries inflicted upon a child which cause its death be inflicted after its delivery. The child must be born alive, but if, after birth alive, it does by reason of a potion or bruises received in its mother's womb, it is "murder in such as administered or gave them."

It has always been difficult to procure conviction in cases like these, the necessary evidence being hard to obtain.

WHERE SURGEONS HELD LIABLE FOR NEGLIGENCE OF HOSPITAL NURSE DURING OPERATION

The Oklahoma Supreme Court holds, Aderhold v. Bishop, 221 Pac. 752, that where a patient engages the services of a firm of surgeons to perform a surgical operation for the removal of a goitre, and goes to an incorporated hospital, owned and operated exclusively by the operating surgeons, for the operation, and where during the operation the services of a head nurse of the hospital and a general employee of the hospital are used by the operating surgeons in the performance of the operation, such operating surgeons are liable to the patient for any negligent act of such head nurse in respect of the service performed by her and made use of by the operating surgeons in the performance of the operation. Under such circumstances the relation of master and servant was held to exist between the operating surgeons and the head nurse during such time as is required for the performance of the operation, although such head nurse may not be in the regular employ of the operating surgeons. The negligence alleged was the burning of the patient's feet and ankles by contact with a pan of hot water used during the operation, or by water dripping from cloths immersed therein.

LIABILITY OF PHYSICIAN FOR INJURY TO PATIENT FROM HOT WATER BOTTLE HELD FOR JURY.

A physician is not liable for the negligence of a nurse who is not employed by him, but where the negligence charged is that of the physician in placing his patient after an operation upon a hot water bottle which should have been removed from the bed, it is for the jury to say whether he was negligent or not. Hale v. Atkins (Mo. App.), 256 S. W. 544.

X RAYS IN EVIDENCE TO SHOW DETERIORATION OF INJURED HAND.

In an action for injuries to plaintiff's hand smashed in a mangle, certain x ray photographs of the hand were introduced showing the progressive stages of its deterioration and the nature and extent of the injury caused by the compression and great heat of the mangle. It was urged that these photographs performed no office as evidence in the case, since the injury was admitted, and the only effect of the photographs was to inflame the passions and prejudices of the jury. It was held, Bledsoe v. Capital City Laundry Co. (Mo. App.), 256 S. M. 1076, that the photographs were essential evidentiary matter to disclose the nature and extent of the injury, as to which the evidence conflicted, and the progressive deterioration of the hand.

BAR OF STATUTE OF LIMITATIONS TO PHYSICIAN'S ACCOUNTS.

In an action by a physician against the estate of a patient who had died, the account, which was itemized, had run from 1906 to 1921, and the only question was whether or not the items, except the last four, were barred by the Oklahoma Statute of Limitations. If the account was a mutual open account, the bar of the statute would not commence to run until the date of the last item; but if a simple open running account, it would commence to run from the date of each particular item. The Oklahoma Supreme Court held, Sharp v. Miller, 221 Pac. 747, that it was not a mutual account, under the rule that an account consisting of items on one side and only payments on the other is not a mutual account, in which each party has a demand or right of action against the other. There being no ratification by the patient during his life or waiver of the statute of limitations, the items were held barred.

The Modern and Technical Study of Heredity*

CHARLES L. DANA, M.D., LL.D.,
New York
Professor of Nervous Diseases, Cornell University Medical College

Heredity is a name given to a biological process, by which the characters of body and mind are transmitted from parent to offspring. The study of heredity includes a study of the biological process itself, which is an analytical and synthetic attack, and a study of the clinical phenomena of heredity, which is a descriptive attack.

Very properly, yet only recently, heredity has been taken up by the biologist and become a laboratory study. In the biological method of studying heredity, there have developed new terms and a modern discussion on heredity involves almost a special vocabulary. It is my purpose to indicate the lines of work that are being followed just now in these biological studies of heredity and to give such descriptions of laboratory work and terms as may help to interpret our clinical observations and make them contribute effectively to the science of heredity as a whole.

Heredity is one phase of the more general subject of genetics, a science which deals with the coming into being of organisms and which includes not only parental influence, but all environmental influences which in some way affect the bringing into being of a new organism or race (1).

Many students of heredity enlarge their range and call themselves geneticists.

And it would be wise for us who are studying the inheritance of nervous and mental diseases to take the attitude of the geneticist and consider the factor of environment also in so far as it relates to our subject.

In accordance with the definitive character of my remarks, I would like to state what I think should be clearly in mind, when we speak of inherited disease:

Inherited morbidity shows itself in three ways, viz., as inherited organic diseases, as inherited functional disorders and as inherited constitutional predispositions. Inherited morbidity in all these forms must be an inborn heredity. Diseases started during prenatal life, by trauma, infection or malnutrition, are not technically hereditary through these causes. In this sense, there is really no hereditary syphilis or hereditary tuberculosis. But there may be inherited predisposition to these and many other morbid conditions. Inherited abnormalities and defects are often classed as inherited disease and an exact distinction can not always be made. Thus many of the familial diseases might be called abnormalities or mental defects.

Abnormalities of development are often produced by some accident during fetal life, and are not to be classed as inherited disease unless they are passed on later in the form of familial diseases. The fact that particular abnormalities are not necessarily inherited is to be considered in studying hereditary monstrosities, and defective neuropsychic characteristics. Feeblemindedness, for example, is probably often due to a prenatal injury, not to an inheritance and is not necessarily transmitted.

BIOLOGY AND GENETICS

In studying the inheritance of disease, we must pay due weight to the work of the biometricians and the school of Galton. At one time there was great antagonism between the latter group and the Mendelians. It has been stated that, according to Pearson, no inheritance is Mendelian; while according to Davenport all inheritance is Mendelian. Of late this situation has somewhat changed. The grounds covered have become somewhat different. The biometricians deal with statistics and mathematics in relation more especially to the general problems of population and social life. The Mendelians are dealing with the living cell and its mechanisms in relation to heredity. The biologists in studying heredity seem now for the most part to be working along Mendelian lines. Their work involves a great deal that is highly technical and it has adopted a stupendous vocabulary. It is, however, extremely interesting and is a vital phase of the science of inheritance. So I would like to refer to some of its data and methods.

In the substance of the cytoplasm of a plant cell is a nucleus which contains a chromatic network that breaks up into granules and pairs of bodies called chromosomes. Every cell of the body has a constant number of paired chromosomes, and they are one half from the male and one half from the female.

*Read at a meeting of the Association for Research in Nervous and Mental Diseases, December 26, 1923.

Copyright, 1924, by A. R. Elliott Publishing Company.

They are supposed to carry "factors" that determine the characteristics of heredity, e.g., tallness, shortness, albinism, pigmentation, etc. This special factor is called a "gene" or "id." It is of the nature of an enzyme, secreted by the nucleus. A gene has no anatomy and no chemistry; it is spoken of as a "mood"; but it is a structural peculiarity in the chromosome and it occupies a particular part of the chromosome. A gene for color is one which causes pigmentation, while in the absence of this color gene there is albinism. Changes in the genes are the cause of variability in inheritance or "mutation" (2). There is a number of these genes in a chromosome; they vary in character and this explains blending of inheritance. Thus where a black rabbit is mated with a white one, a gray colored rabbit results, there being at least five different kinds of genes in the chromosomes.

It is believed that chromosomes never fuse absolutely, and on this fact it is inferred that individual characters are not actually blended, but that the hereditary characters making up a personality, or a defect or a disease, are the results of the segregation of individual unit characters, anatomical or functional.

MENDELISM

These biological data bring us to the subject of Mendelism, which seems to be widely accepted now as the basis of the biological mechanics of heredity. The essential features of Mendelism as it affects our problems are, that an organism is made up of unit characters and that a real blending does not take place in the reproduction of offspring. Hereditary characters, to put it more explicitly, are independent units (usually) which segregate upon the fertilization of the female by the male, regardless of temporary dominance. (2). This general statement can be elaborated into two specific laws:

First, the law of dominance: When two organisms of different unit characters are crossed, hybrids result and these hybrids are all apparently alike and have the character that is dominant in one of the ascendants, i. e., they are all tall or short, etc.

Second, the law of segregation or disjunction: If these hybrids are bred together, their offspring, forming a third generation, will consist of fifty per cent. which are like their hybrid parents, twenty-five per cent. like the male procreator and of pure stock, twenty-five per cent. like the female and also of pure stock. If S represents the original male and s the female, the formula for the grandchildren is S+2Ss+s.

The main points viz., that of the unit character of inheritance and of the influence of the dominating and recessive qualities, may be shown in the following illustrations: Assume that: M is a dominant character (assume it to be "hereditary chorea"). Assume that N is a recessive character (i .e., "normal neuromuscular mechanism"). Now if one breeds M N with N N there results fifty per cent. M N plus fifty per cent. N N, which means one half are sick, one half well, or if N is dominant all would be well.

Suppose further that M is recessive and N dominant, then breeding two hybrids M N with M N gives twenty-five per cent. M M plus fifty per cent. M N plus twenty-five per cent. N N equal one half sick, three quarters well. (See *Apert L'Heredite morbid*, 1919.)

The data concerning inheritance have been worked out especially in plants and lower animals. They apply in a measure to certain special human characters that may be considered unit characters, such as pigmentation, polydactylism, and perhaps other anatomical characteristics. Tallness and shortness are unit characters in the pea, but in man tallness involves the internal secretions and conditions of nutrition and metabolism that make their quality quite complex. The familial diseases, being really defects more than diseases, are supposed to show Mendelian traits. In fact Mendelism can be applied perhaps more definitely to human defects than to disease.

But on the whole, neurologists and psychiatrists must at present expect to get most help in studying inheritance of disease from the biometrician, from clinical observation and a study of the environment. The application of Mendelian laws to the inheritance of human disease means a long wait.

The following are some of the technical terms in connection with Mendelian heredity:

An allelomorph is a pair of characters of which one is dominant and one recessive. When such a pair is bred, the result is 1+2+1, 1 being pure dominant, 2 hybrid, 1 pure recessive.

A gamete is a mature male or female cell ready for maturation. A gamete is a marrying cell.

A zygote or yoked cell is a fertilized cell formed by the union of two gametes; it is a married cell.

The gene is the factor in the chromosome invisible and undemonstrable anatomically or chemically which gives form and substance to a definite visible unit character in an organism.

A homozygos character is one which is present in the offspring in double quantity because it was present in both parents.

A homozygote is an organism which is homozygous (double dose) with respect to any character.

A heterogote is an organism which derives the determiner of its character from only one parent.

NOSOLOGY OF INHERITED DISEASES

I would now like to call attention to the classes of nervous and mental disease to which laws of inheritance are to be applied; they are: Familial diseases, or diseases of similar heredity. These are diseases which have been evolved into a family and become part of its chromosome pattern. Familial diseases are those which tend to create out of apparently normal individuals a type that is abnormal and one that is degenerate in character.

The familial diseases are characterized as follows:

a. There habitually develop several subjects of the diseases in the same generation.

b. The cases develop in the same way and with the same characteristics.

c. They develop out of a constitutionally neuropathic constitution and independent of any external pathogeny.

d. They are rarely cases of direct heredity, i. e., passing from father to son, etc.

The principal familial diseases are: Heredity ataxia of Friedreich; congenital familial

bleheroptosis (Moebius); familial spasmodic paraplegia; amaurotic idiocy (Tay-Sachs); familial or hereditary optic neuritis; the progressive myopathies; familial periodic paralysis (Westphal); familial nocturnal enuresis; essential or familial polyuria; essential hereditary tremor; chorea of Huntington.

Apert makes the following groups of hereditary nervous diseases:

Familial diseases with a continuous heredity—Here the disease is transmitted from parent to child and never skips a generation, e. g. Huntington's chorea.

Fraternal familial disease—The patients are the children of healthy parents, but one finds the disease in a collateral ascendant like an uncle.

Diseases of matriarchal heredity—Here descendants of affected males always escape, and only those descendants of the common stock on the mother's side are affected. In some cases the disease is perpetuated in continuity from mother to child, the daughters always carrying the malady. This is seen in familial periodical paralysis and Daltonism. The disease also can be perpetuated by the female who does not have the disease, as in familial papillary atrophy or hereditary optic neuritis. In these cases the disease has the character of a dominant.

DISEASES OF DISSIMILAR HEREDITY

In diseases of dissimilar heredity, there is a transmission of a morbid aptitude, i. e., a constitutional predisposition to a nervous disease, but the disease transmitted may be the same or may be different in the offspring from that of the parent. Illustrations of this are families in which there may appear one or other of such maladies, as epilepsy, migraine, the psychoneuroses, Basedow's disease, and family tremor. The constitutional psychoses, such as those of the manic depressive and dementia precox types, morbid alcoholic craving and similar constitutional states of dependency on defective inhibition. The mechanism of the transmission of these morbid aptitudes, is one of the objects of biological research.

There is a large class of diseases in which poisons or infections during prenatal life induce enfeebled or neuropathic constitutions, which make the descendant liable to acquire the parental disease. Such diseases are tuberculosis and syphilis. These are not cases of the heredity of nervous diseases and their study comes more properly under the head of congenital disease.

It seems, however, possible that defects or anomalies in the nervous mechanism produced prenatally by certain accidents, may be inherited, indeed it is only in this way that we can explain the origin of the familial diseases.

Characters acquired prenatally, may be transmitted but, despite Prof. Kammerer, is seems to be still pretty well agreed that in the higher animals, characters acquired postnatally are not inherited.

A Scourge of Hemolytic Streptococcus*

VIRGINIUS DABNEY, M.D.
Washington, D. C.

The pandemic of respiratory infection due to the hemolytic streptococcus which swept over the world during the World War, called for convenience influenza, is only too easily remembered and constitutes to those of us who passed through it one of the most ghastly and fearsome experiences which can come to a medical man. Even during the Civil War it was observed that the troops from remote country and mountainous regions, where contact with others was infrequent, were soon stricken with those diseases ordinarily associated with childhood, when they were brought into camps and grouped with many others. Not only was the incidence large but the severity of the infections and the deaths from complications were especially marked. Similarly, during the World War, these same diseases were prevalent and for the same reasons, but in addition the grouping together of so many thousands, frequently under most adverse climatic conditions, rendered the contagion almost certain to spread. To the danger of this condition was added the hemolytic streptococcus as a complicating secondary invader, and this organism, instead of being attenuated by passage through so many hosts, was rendered more virulent and not only conferred no lasting immunity, but converted those who escaped death into carriers. In fact, they became

*Read before the District of Columbia Medical Society, March 6, 1924.

a distinct menace to the public and at times were themselves sensitized to attacks of infection dependent on the presence in their throats of streptococci. During the past five years this condition has become increasingly dangerous and I think it will be five more years at the least before it can be brought under any control.

The family with whose trying experience this paper is concerned had no inherited or acquired taint of any sort and all of them led the simplest, most hygienic lives possible. They slept out doors, got ample sleep, had no digestive irregularity, were never constipated and were as nearly normal as any family can be under present living conditions in a city such as Washington.

FIRST EPIDEMIC

The first invasion lasted from December, 1918, to February, 1919, resulting, during the two months, in five cases of influenza, one of lobar pneumonia, two of middle ear abscesses, one of suppurative ethmoiditis, and one of impetigo.

Case I.—A. N. D., mother of five children, all healthy, contracted influenza (i. e., streptococcic pneumonitis), rapidly sinking into a comatose state on the third day. Her condition was critical from the first, and she was not expected to live after the fifth day. She was often pulseless. Was transfused three times with socalled immune serum. On the twelfth day she regained consciousness for a while, but was frequently irrational. Recovery without complication after two months in bed.

Case II.—T. D., a boy of eight years, was infected a few days after his mother. Lobar pneumonia developed a week later, with apparent convalescence in ten days, but relapse a week later. Area of dullness on one side, thought to be fluid, was aspirated with negative results. Recovery in two weeks without complications, though he complained for some months of pain in side, apparently from pleuritic adhesions.

Case III.—W. N. D., a boy of four years, came down with influenza the same day as his brother (Case II). Prostration was severe for a week, at which time a severe otitis media developed; drum was incised and the discharge was free for ten days.

Case IV.—F. N. D., a girl of three years, was taken sick the day after the patient in Case III, with marked toxemia from the first; prostration was grave. Recovery in ten days, at the end of which time an acute otitis media developed. The drum was incised; ear was dry in ten days.

Case V.—L. D., a girl of eleven months, contracted mild influenza, but a virulent infection of the ethmoids. Both eyes were nearly closed, pus streamed from both nostrils, requiring suction three times a day; temperature for three days at 4 p. m. was 102°. Recovery in two weeks. (The nurse who held this child in her lap for hours at a time did not contract any infection of any sort at this time, but two years later died of a hemolytic streptococcic infection of the larynx and heart valves. This case will be reported at length later on.)

Case VI.—P. D., a boy of six years, had been sent away as soon as the epidemic struck down his mother and brothers and returned to the house after all were well and the house well cleaned, only to manifest an extensive impetigo of the face and hands. This it is well to remark, is a streptococcus infection of the skin. Incidentally he was the only one of those infected by this organism whose tonsils had been removed, and he escaped with only a skin infection. This point is worth remembering when a consideration of the etiology in this family's epidemic is reached.

In attempting to prevent the spread of the infection in this family isolation was at first attempted but later abandoned as it proved useless and added to the difficulties of care and nursing. However, ventilation was rigidly enforced in all rooms containing the sick. From every discharging ear in this group and from every nose, throat and mouth was secured many times the hemolytic streptococcus, which organism constituted about ninety per cent. of the bacterial growth in the tubes, the remaining organisms being the staphylococcus aureus and the fusiform bacillus. However, from the middle ear discharge the growth was purely the hemolytic streptococcus. As the tonsils seemed healthy, small and showed no secretion or crypts, their removal was not contemplated, nor were any cultures taken, as I regard a surface culture of a tonsil as perfectly worthless. Such a culture, if negative, would not exclude the necessity of removing the tonsils, and, if positive, would not necessarily indicate the necessity for removal. About the only reason I can see for such routine cultures which many laryngologists make is to frighten a patient into having the tonsils removed as every tonsil will yield a flora that when listed on paper will put the fear of the Lord in the heart of a patient who is ignorant of the fact that every tonsil will show on its surface a formidable array of bacteria. Thus, these patients had for a year and a half an uninterrupted period of excellent health with no clinical tonsil symptoms whatever. However there occurred a second invasion.

SECOND EPIDEMIC

In February, 1921, the second invasion occurred resulting during three weeks in two cases of mastoiditis, one of abscess of the larynx, one otitis media one impetigo, one scalp abscess.

Case I.—A. N. D., the mother, came down with a violent earache; the drum was incised within two hours of the beginning of the pain, but despite every effort the case went to operation on the eighth day. For two days the evening temperature touched 105° and then declined very slowly, and there was a sustained evening temperature of 99.2° and 100° for four weeks. This was a typical hemorrhagic infection.

Case II.—B. B., colored nurse to the children, complained of malaise, but did not go to bed as she felt she was so badly needed that she wanted to keep going. In two days, however, she had to give up and her hoarseness and brassy cough were marked. Her fever touched 104° and her breathing became so labored that she was taken to the hospital. Examination showed an enormously enlarged epiglottis, edema of the base of the tongue and a foul, watery discharge bathing all the parts visible. She was also able to raise a little of this from below the glottis. Under appropriate treatment in twenty-four hours she was much improved, the edema so far receding

as to allow a view of the cords, not possible the day before. In two days her temperature dropped to normal and she seemed certain to recover, though she could not talk above a whisper and still had some difficulty in swallowing. I was called at four in the morning and found her sitting up in bed, her respiration very difficult and her pulse intermittent, but I feared to wait and did a rapid tracheotomy with apparently good results. However, she lapsed into unconsciousness and died in four hours from acute cardiac dilatation. Thus, the dyspnea was not of tracheal origin but cardiac; in fact, most of such cases are of this type. There was no sign of a deep cervical abscess, and no collar of induration was present.

Case III.—T. D. Just before this boy's mother went to the hospital for her mastoid operation, he had both ears opened after an earache of only half an hour's duration. However, he came to operation on the fourth day with typical findings, but his convalescence was much smoother than his mother's, probably due to the fact that he did not become so toxic before operation, and this, too, despite its being a bilateral operation.

Case IV.—P. D. Three days after his brother's infection began, this boy had his drum opened and the discharge was so profuse and the local disturbance so extensive that several times the necessity of an operation on his mastoid was debated. The discharge was maintained for two weeks.

Case V.—L. D. This three year old child seemed destined to escape the infection that had caught the others, but three weeks after the beginning of this second invasion an extensive impetigo developed on the face and minute abscesses about the roots of all the nails of one hand and three fingers of the other. Apparently she infected her scalp, for an immense, dissecting abscess developed there just over the posterior occipital protuberance which required a wide incision and dressing for nearly six weeks.

Case VI.—W. N. D. Five months later (July-August) this boy began to show an evening temperature of 99° to 100° and kept this up for six weeks. He did not appear or feel ill, but all examinations were negative till we searched the tonsils, where a deep crypt was found. This kind of evidence was not conclusive to me, but after the experience of this family with the hemolytic streptococcus the removal of the tonsils was determined upon.

In the spring of 1922 the tonsils of the mother and four of the children were removed, despite the absence of any gross disease, crypts or hypertrophy. Probably cultures would have revealed many bacteria, among them the hemolytic streptococcus, but, as I had no intention of being guided by the presence or absence of these organisms secured by surface swabs, I decided that the clinical aspects of the cases strongly suggested that they were carriers and for this reason alone were the tonsils removed. From the anterior crypts of every one of the enucleated tonsils was found in pure culture the hemolytic streptococcus. The tonsils of the mother I had many times examined and always had regarded them as very small, normally atrophied remnants, smooth and porous; yet, on separation and removal they proved to be the size of the end of one's thumb and thoroughly diseased. It is a point of speculation as to how far her two attacks of serious infection caused this degeneration, and I am of the opinion that the tonsils were healthy till these two invasions occurred. Similarly, two of the boys showed caseous material beneath the capsule and evidence of deep seated inflammation (adhesions, bands and fibrous tissue). However, the physical ordeals of this family were not yet over, for again there occurred a third invasion.

THIRD EPIDEMIC

July-August, 1923, the third invasion occurred, resulting in seven cases of sinus infection, six of influenza, and three of otitis media, complicated by suppurative chondritis.

These cases can be summarized briefly as they were so similar in course and incidence. The mother had a true influenza with moderate prostration, remaining in bed a week, the temperature never going over 100°. She got up on the eighth day and almost immediately had a relapse, with a fever of 103°, great prostration, and backache, infection of the sinuses and a distressing feeling of numbness over one side of the face, almost an anesthesia. The stoppage of the eustachian tube was absolute, with deafness and fullness in the ear. Her convalescence required six weeks. At intervals of five or six days the children came down with the same infection, though not so virulent, all five having profuse sinus infections which required irrigation three times a day. In addition, in three of them middle ear abscesses developed, with infection of the canal, pinna and periostitis of the mastoid. These attacks lasted ten days and the suffering from the chondritis was great. All the patients were thoroughly toxic and lost all that they had gained by their outing at the seashore, where they were at the time. Also, this time the father had the same sinus infection, anesthesia of the face and blocking of the tube, without any systemic infection. So far as can be now seen these three serious epidemics have left no cardiac disease, though it is possible that in the years to come the cardio-renal mechanism may prove to have been injured and some hypertension result.

CONCLUSION

In the light of subsequent events, it seems certain that after the first epidemic this family must have become carriers, yet they went nearly two years without any clinical manifestation of their condition. However, the carrier is, of course, more a menace to the community in which he moves than to himself, and it is here that the great increase in the presence of the hemolytic streptococcus can be met and overcome. On the other hand, it must not be overlooked that the carrier at times becomes sensitized to the very organism which he is harboring and then becomes a source of danger to himself. This phase is shown by the second epidemic (ear, mastoid, laryngeal and skin manifestations), though two members (P. D. and the colored nurse) did not have any tonsils. They were almost certainly infected by the other members who were carriers. Thus, this family shows vividly the several phases of the carrier problem: first, they become carriers, they then show a sensitization to and are overcome by the same organism that they are harboring themselves. Later, they infect two members of the household, despite the

fact that these two were especially resistant, being without tonsils, and who had not shown any streptococci after recovery from an infection two years before.

The third invasion is not an aspect of the carrier problem, I believe, though a very striking coincidence, as all tonsils in the family had been removed. There was a local epidemic of influenza where they were living, of the same type as their's and complicated by the same prolonged convalescence and prostration; so it was due to this condition and not any carrier element. It is true, however, that the hemolytic streptococcus did complicate the attack. I will repeat here that in all three epidemics the hemolytic streptococcus was recovered from ear, nose, throat, larynx or mouth as the case may be. Every effort was made to remove any infection that might have clung to the house itself or its furnishings, the most thorough cleaning and disinfecting of everything being done during the attacks and in the intervals between. Thus, this would appear to exclude as a cause contact with infected clothing, furniture or utensils.

THE HEMOLYTIC STREPTOCOCCUS MENACE

The frequency with which in the past four or five years respiratory, ear and sinus infections have been complicated by the presence of the hemolytic streptococcus, either as causative or as a secondary invader, and the ravages of this agent when so found constitute a definite and most serious pathological problem. The socalled hemorrhagic mastoid case of years gone by was certainly a rare form of mastoid disease as compared with other forms of infection, but it is so no longer. In my own experience certainly fifty per cent. of mastoid operations have been found associated with this agent as a direct cause of the necrosis. Moreover, so virulent is the infection here that operation is imperative often on the third or fourth day after myringotomy or spontaneous rupture. All of those who were infected during the World War or since, and who did not die and returned with their tonsils *in situ*, have been scattered all over the country and established themselves as active infectious agents in incalculable number, as they have increased by geometrical progression. Now there are certainly more infected ears, noses and throats, as well as bronchi than ever before. This widespread dissemination of a deadly organism is appalling and has proved in its concrete results of fatal illnesses due to the streptococcus that it is not merely an academic, theoretical problem, but one of vital, practical interest to the entire community. While I should regret adding to the lust for blood of those who are industriously engaged in removal of any tonsil that is visible, yet one of the incidental and accidental results of this "massacre of the tonsil," as John Mackenzie so aptly terms it, will be the elimination of many of these carrier cases. However this may be, I regard the hemolytic streptococcus in its widespread presence as a causative and complicating organism in disease as one of the most serious and pressing problems which the medical profession faces today. This can be met only by the elimination of the carrier and thorough enucleation of the faucial tonsils offers the greatest hope for attaining this end, for these glands are certainly the chief nidus of the hemolytic streptococcus in the carrier.

1633 Connecticut Avenue.

The Importance of Posture in Postoperative Treatment

WILLY MEYER, M.D.,
New York

When as a young student in medicine I attended the lectures of the late wellknown Professor Zenker of the University of Erlangen in the winter of 1877-78, he closed the season's last address to his class with the words: "Remember, gentlemen, prophylaxis, the prevention of disease, is the highest aim of medicine." These words were indelibly engraved upon my memory. During my entire medical life I have watched with the keenest pleasure the evolution of medicine and surgery from this point of view, and have followed with the highest admiration the incessant, often selfsacrificing work of medical men to prevent disease in all the branches of our science. I have also personally tried to do my little mite whenever and wherever possible and to live up to my esteemed teacher's impressive words.

What has been accomplished in the way of prevention of disease is known to all of us and to the world. I will but remind you of Jenner's immortal achievement, the vaccination against smallpox, and the now uniformly introduced successful inoculation against typhoid fever, diphtheria, cholera, even yellow fever, and many other infectious diseases, of which the infecting microbe has been found and cultured. So the entire apparatus set in motion everywhere, in private practice and hospital work, before and during operation, all of what we call antiseptic and aseptic surgery, is nothing but a detailed and determined attempt, founded on definite scientific knowledge, to prevent disease, to render infection impossible.

Now, just as our endeavors in surgery, preoperatively as well as during the operation, are important to prevent disease and complicating affections, so must our endeavors be constant after the operation, when the patient is being and has been returned to his bed, when aftertreatment has begun.

Of the many important factors that here come into consideration I shall at this time pick out just one —posture. Posture in all its varieties is, to my mind, one of the most powerful means at our command to hasten recovery and avoid complications. Of the various postures introduced into practice I shall here consider principally two, which I have practised for a great number of years in hospital and private work, alone as well as combined with others

—the slight Trendelenburg posture and Sims's posture, or the latter more exaggerated, the abdominal posture.

THE SLIGHT TRENDELENBURG POSTURE

When a patient has successfully gone through the immediate dangers of the operation and the first part of the aftertreatment, and he, as well as the others concerned in his welfare, feels easy and is looking forward to a speedy and uninterrupted recovery, there is still one treacherous enemy lurking in the background ready to strike at any moment—venous thrombosis.

This thrombosis usually concerns the left femoral vein, following work done by the surgeon in his everyday routine, also one or more of the pelvic veins after operations on organs within the small pelvis and after childbirth.

From a pathological point of view such blocking of the venous lumen is not a serious matter. The lower extremities and the respective pelvic organs easily stand the disturbance in the normal return flow of the blood to the inferior vena cava. Collateral circulation is plentiful and the concomitant edema of the extremity—though usually at first greatly alarming the patient and his relatives—subsides after a certain time. Its persistence is very rare. Surgeons are used to ligating the deep femoral vein, for instance, in the operative treatment of the so-called thromboangiitis obliterans, and no interference with the ordinary circulation is seen. With aseptic healing a thrombus forms immediately adjacent to the ligature and usually extends up to the spot where a lateral branch enters the ligated vein. In phlebitis the coagulation does not remain quite as local. The thrombosis forms as far as the venous wall has become inflamed and more or less edema develops in the lower extremity, at least, if the femoral vein is involved. Thrombosis in branches of the internal iliac vein may run on without any external manifestations; an unexplainable tachycardia is taken by many as the only outward sign. If the inflammation spreads to the external branch of the common iliac vein, edema of the leg and thigh may become alarming. I need but remind you of the so-called phlegmasia alba dolens after complicated childbirth.

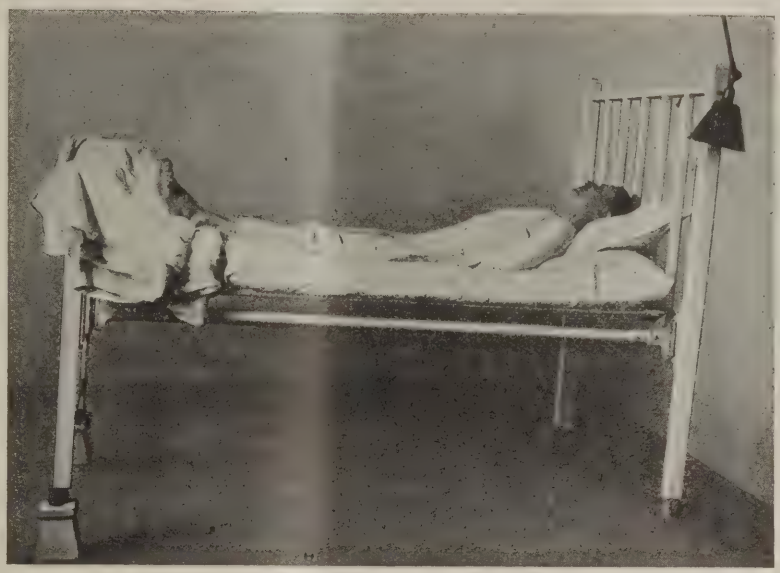

FIG. 1.—Slight Trendelenburg posture, with patient on his back, resting. This is the standard posture for all patients operated on below the level of the heart; also for weak patients, operated upon head or neck, who cannot get up early.

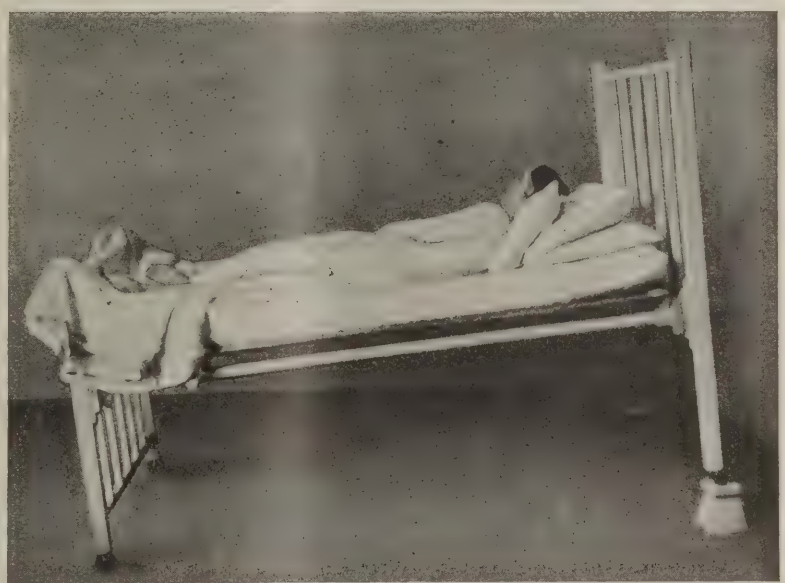

FIG. 2.—Sims's and slight Fowler's posture combined during the first three days after gastroenterostomy.

What medical men fear is the clinical sequelæ of the thrombosis: the loosening of a part or of the whole length of the thrombus, which then enters the circulation and is driven as a foreign body through the right heart into the lung. What we fear is this sudden pulmonary embolism, the sudden interruption of the normal physiological circulation of the blood between the right and the left heart by way of the lung, partially or completely, which sets in like a flash from the blue sky and is absolutely beyond the control of the attending physician.

I spoke before of the thrombosis of the left femoral vein. Why only of the left and not also of the right?

It is a clinical fact that at least ninety-five per cent. (if not ninety-nine per cent.) of thromboses of the femoral vein occur on the left side; and if both veins become involved, one after the other, that the trouble almost always starts with the left. The reasons for this peculiarity are principally anatomical.

We know from the investigations of the Freiburg

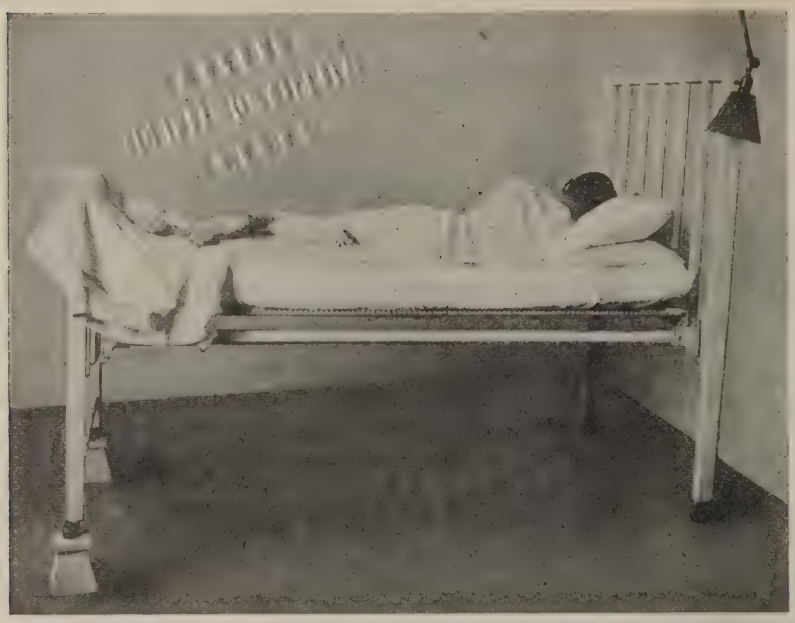

Fig. 3.—Sims's and slight Trendelenburg's posture combined, as used later on after gastroenterostomy, the degree of lateral posture, as well as the raising of the upper part of the body being left to the patient's convenience.

pathologist, Ludwig Aschoff (1) that thrombosis occurs in those portions of the venous system in which the flow of blood is retarded provided micro-organisms circulate within the blood.

With the patient in the usual horizontal posture in bed after an operation, the upper part of the body from the hips up being supported on pillows, there is no place in the body where venous circulation is more impeded than in the groin. Poupart's ligament, often strained, presses upon the femoral vein as it runs across the horizontal branch of the pubic bone. From here on the blood has to run uphill in order to reach the inferior vena cava. Further up, on the left side, the right common iliac artery or the lowest portion of the abdominal aorta crosses the common iliac vein in front of the spine, whereas on the right side the external iliac vein passes underneath the external iliac artery, a much smaller vessel, in order to reach the common iliac vein and inferior vena cava. Here also the soft belly of the psoas muscle forms the pillow on which these vessels run. The difference in the circulatory arrangement of the right and left sides is due to the anatomical fact that the inferior vena cava runs nearer to the median line than the abnormal aorta. Further, before the common iliac vein reaches the place where it has to pass under the strong and ever pulsating common iliac artery, the sigmoid flexure of the colon, usually filled with inspissated fecal matter, rests upon it for quite some distance.

These factors have been accused of being principally responsible for the clinical fact that postoperative femoral thrombosis is almost exclusively met with on the left side. It is, of course, possible that in addition to these anatomical conditions minor factors often come into play in its development. Repeatedly I have been asked, when speaking on this subject before my assistants and students, why has not this complication been seen more frequently in medical cases which have been helpless and bedridden for many months, why principally in patients that have been operated upon? My reply has been that the ordeal, which we call operation, opens up a great many ports of entry through which microbes may reach the circulating blood current. It takes time, likely a few weeks, before the slowly recuperating system gets rid of them. Usually it is the second week after operation in which the thrombosis of the femoral vein occurs.

Besides, the effect of the general anesthesia may contribute to thrombus formation. It will be interesting to watch and observe, whether regional and local anesthesia, employed nowadays in so many major and minor operations, will reduce its occurrence. Weakness of heart muscle must also be considered in the etiology of thrombus formation.

Fortunately, femoral as well as pelvic thrombosis, as such, is rare. Yet, I am sure, every busy surgeon has met with it. And whoever has gone through the worry and annoyances it has produced, particularly in private practice, will never forget it. Very vividly stands before my memory an experience of one of the first years of my surgical practice. I had been called to operate upon a patient with acute appendicitis in a private residence, and had to go ahead at midnight. The patient was the only daughter, in fact, the only child in the family. Everything went well at first, and in the beginning of the second week, when asked again concerning the prognosis, I expressed myself as sanguine and extended the hope that the patient would be out of bed a few days later. During the following night she complained of pain in the left groin, which in-

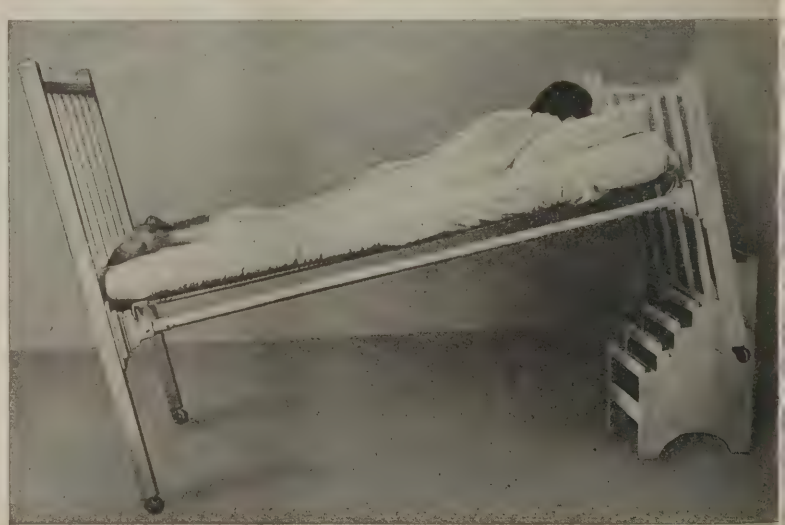

Fig. 4.—Abdominal posture combined with Fowler's, increased by raising the upper part of the bed on the steps. This is used in cases of intraabdominal perforation of any sort with large effusion, both lumbar regions and the small pelvis being drained through intramuscular stab wounds on both sides.

creased from hour to hour, in spite of an icebag immediately applied. Soon the leg began to swell, and a typical femoral thrombosis developed. Not long after the femoral vein on the right side followed suit. It was more than six weeks later before I dared to allow the patient to be out of bed. The people I had to deal with were very nice; still, I sometimes felt that they blamed me for the complication.

On looking back, several cases of thrombosis reenter my mind which occurred during the first two decades of my forty years of continuous surgical practice. I have seen it after the most aseptic surgical interferences as well as after operations for acute intraabdominal inflammations. I have seen left femoral thrombosis set in after an operation for hernia, after the radical operation for cancer of the breast, also subsequent to operations for acute appendicitis and perityphlitic abscess, following suprapubic cystotomy, etc. Never can I forget when the father of a well known colleague here in New York, after a suprapubic lithotomy done by me at his home, developed a left femoral phlebitis which evidently gradually extended farther up into the iliac vein. It was many weeks before the pronounced swelling of the lower extremity began to recede somewhat. A marked difference in the size of the two lower extremities persisted; he had to wear a rubber stocking that reached almost up to his hip and required special suspenders to prevent it from slipping down, a procedure which proved to be a great hardship for the patient. Barely two years later he died suddenly with symptoms of a pulmonary embolus.

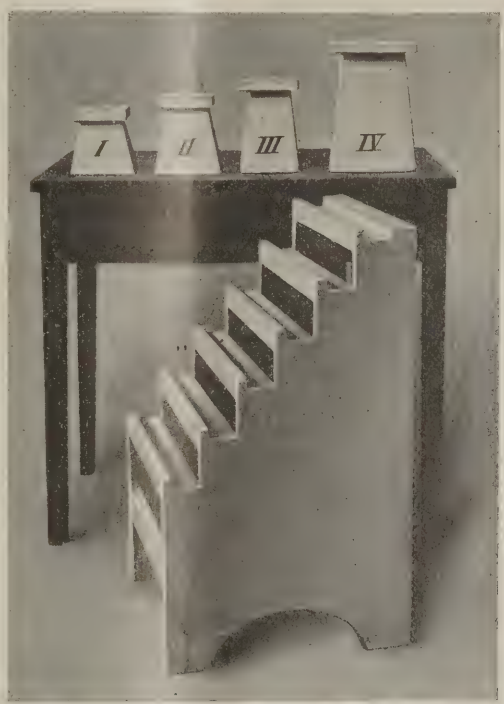

FIG. 5.—The four sizes of blocks and "the steps" as used for elevation of head or foot end of the bed at the Lenox Hill Hospital, New York. The height of the blocks is respectively five, six, seven and ten inches.

On one occasion when I was visiting a semiprivate patient of mine at the hospital I saw his roommate, who had been operated upon by one of my colleagues for a stone in the kidney, drop dead upon his first attempt to walk to the window of the room. Naturally, all concerned in the case were utterly distressed. Autopsy showed an embolus riding on the bifurcation of the pulmonary artery.

I could cite other cases of the same type, as vivid in my memory as if they had occurred today. The fact that I have also seen patients with a pulmonary embolism recover under my hands might be worth mentioning, but does not fit in the realm of the present discussion.

So much is sure, and I wish to repeat it, whoever has met with this complication in practice, striking as it does so suddenly and with unexpected deadliness later on after operations, when the patient may be up and about again and ready to leave the hospital, or sick room, will never forget it.

No wonder that it has excited the interest of many medical men! No wonder that it has been thoroughly investigated and frequently discussed! I myself wrote a brief paper on the subject twenty years ago (2) and have always tried my utmost to prevent its occurrence in my patients.

Can it be prevented? Yes. I believe it can, perhaps not absolutely, but surely reduced almost to a minimum.

It stands to reason that if we can overcome the normal anatomical impediment in the circulation of the lower extremity at Poupart's ligament and further up in the pelvis, the principal cause for the formation of a phlebitis and therewith of a thrombosis would be successfully met. This we are able to do. Just as we allow our automobile to run faster before we approach a hill right ahead of us, and then see it climb up, usually without changing the gear, in the same way we can make the blood current in the femoral veins faster, and thereby for the blood the ascent from the lower extremities to the right heart easier if we raise the lower end of the bed, that is to say, if we arrange for a slight degree of Trendelenburg's posture (Fig. 1). Blocks placed under the foot end of the bed[1] (Fig. 5) will allow the blood within the lower limbs to run down hill from the toes to the hips, and in its onrush it will easily reach the veins in the upper pelvis, nay, I am sure, often the region of the renal veins, from where the negative pressure existing in the thorax, the suction of the right heart, will substitute the decreasing velocity of the blood current.

I am absolutely convinced that this simple means of raising the lower end of the bed is the most powerful weapon we possess of preventing the occurrence of femoral (and pelvic) thrombosis. I am using it after every case of operation at or below the level of the heart, in weak patients also after operations on neck and head, if they stay in bed for some time, and can truthfully say that I have not seen the typical thrombosis of the left femoral vein occur since I started doing this. In my paper on this subject, already alluded to, I mentioned that "it would be interesting indeed if experience would show that by such raising of the lower end of the bed the occurrence of femoral thrombosis could really be prevented; that is to say, if we found that the complication occurred only in such cases where this prophylactic measure was omitted." Today I can state that this proof has been rendered.

Last year, for the first time in many years, after a cholecystectomy, I saw a patient already out of

[1]At the Lenox Hill Hospital, New York, four different sizes of blocks and "steps" are in use for obtaining the postures desired for the given case.

bed two weeks after operation, suddenly and unexpectedly die under the unmistakable clinical symptoms of pulmonary embolism. She had made a smooth recovery, except for pronounced postoperative vomiting, and had been treated as usual with elevation of the lower end of the bed. Unfortunately, the family would not allow an autopsy, much as I tried to get permission for it. Therefore I cannot prove the correctness of the diagnosed cause of death. Still, the tragic suddenness of the exitus in the midst of seeming wellbeing and the immediate marked paleness of the face spoke for it. The patient had had a number of children and may have harbored in her pelvic veins a thrombus for many years. She had not developed a femoral thrombosis during the aftertreatment.

I would like to cite another case illustrating how a prolonged Fowler's posture can favor femoral thrombosis. As will be mentioned later on, I am in the habit of treating my patients with resection of the stomach and gastroenterostomy with a slight Fowler's posture during the first few days after operation. A lady of forty, in whom I had resected a cancer of the stomach that had developed on the basis of an old ulceration according to Billroth's operation No. 2, liked the posture very much, and begged to remain in it longer than the usually allowed three days. Just at that time I had to leave town for a few days, and thus it occurred that she had the head end of the bed raised on blocks for ten days. At about that time she began to complain of pains in the groin and tenderness over the left femoral vein. She soon also developed some edema of the extremity. Of course, the position of the bed was quickly changed, but the annoying symptoms of the femoral thrombosis lasted longer than any other sequelæ of the operation.

I would also like to mention an observation recently made in two patients, one after posterior gastroenterostomy for duodenal ulcer, the other after an operation for a gangrenous appendix. In both cases a painful swelling occurred in the soft parts of the left leg, accompanied by fever and tenderness over the calf, which developed two to three weeks after the operation, and could not be diagnosed otherwise than representing a deepseated localized phlebitis between the muscles of the calf. In both the lower end of the bed had been elevated continuously since right after the operation. Both patients got well after about two to three weeks without any further untoward symptoms.

A third case of the same type I saw recently in the practice of another colleague. This patient, too, got well.

The favorable preventive effect of "posture" has for many years been methodically assisted in every one of my operative patients by frequent motions, particularly of the left lower limb—I call it bicycle riding in bed—and by deep and frequent breathing exercises during the first one to two weeks after the operation. This latter addition I consider particularly important.

As stated already, it is possible that other factors may play a rôle in the development of venous thrombosis besides the usual horizontal posture of the patient in bed, for instance, the anesthetic. It is a fact that in some patients the expiratory air still smells of ether or anesthol on the second or even the third day after the operation. It stands to reason that the elimination of the anesthetic from the system by way of the blood in the lungs will occur more quickly if we insist on regular, slow, frequent, and deep breathing exercises immediately after operation and also later on. In the first days the anesthetic will thus leave the system faster; later on, the methodic breathing, done principally under the supervision of the attending nurse, may prevent pneumonia, particularly in the old. None of us ventilate our lungs sufficiently. The reason is that we have too much lung—five lobes. The exchange of gases physiologically necessary to sustain life can well be sustained by superficial breathing. Were it not for an occasional sigh or a hearty sneeze many of us would not breathe deeply for months. Yet what a sensation of comfort and satisfaction is produced by a deep inspiration. Just think of our vacation time, gentlemen, when we stand on the deck of an ocean greyhound or float in a boat on one of the mountain lakes, how thoroughly every one enjoys the benefit of a deep inspiration! We should also enjoy it in the midst of our busy lives. Just pause and breathe deeply. There certainly will be less chance for atelectasis. By all means we all should make it a point to instruct our patients who have been operated upon to practice methodical deep breathing.

In weak patients and also after severe intraabdominal and intrathoracic work I have added for many years to the precautionary methods, already alluded to, a prophylactic subcutaneous stimulation of the heart muscle by means of camphor, caffein, digalen, or digifolin and other preparations, beginning methodically immediately after the operation and continued for a number of days. Later on the same medication by mouth is resorted to.

I certainly can truthfully affirm that femoral thrombosis is unknown in my division in the hospital and also in my private practice since the strict and methodical application of the previously mentioned procedures have been practised by me during the last twenty years.

SIMS'S POSTURE, ALONE, AND IN COMBINATION WITH FOWLER'S AND TRENDELENBURG'S POSTURE

I still mention briefly the beneficial effect of another posture which I have been using in postoperative treatment of my patients for many years, that of Sims. Of the postures that are at our disposal during and after operation, Sims's posture is surely one of the most useful I know of.

Personally, I believe that a patient with acute gangrenous appendicitis, with its frequently present seropurulent or purulent effusion into the peritoneal cavity, fares best if the abdomen is drained with the help of Morris's cigarette drain, which carries a rubber tube in its centre, or has an additional entire or lengthways split drainage tube—I call the latter a gutter drain—attached outside. I put this drain into the lower end of the usually practised pararectal incision down to the bottom of the same pelvis and close the wound by layer sutures; I also place one or two stitches below the drain in the low angle of the peritoneal, fascial, and skin wounds, so that after removal of the drain, mostly in the course of the

hird day after operation, the buttonhole in these issues can easily close.

I am absolutely opposed to closing up the patient's bdomen after removal of the gallbladder. I believe he surgeon has not the right to take chances with is patient's life for the mere pleasure of seeing the bdominal wound heal by primary union throughout r for the sake of simplifying the immediate after-reatment for the patient as well as for himself. One undred consecutive patients with a cholecystectomy vound closed up airtight and watertight may recover moothly; and the hundred and first may die for no ther reason than that the abdomen was not drained, f the ligature on the stump of the cystic duct gave way and bile containing microbes suddenly entered he closed peritoneal sac. I am furthermore of the pinion, so far as cholecystectomy is concerned, that t is for the best interests of the patient if we start he removal of the gallbladder from the fundus oward the cystic duct and not in the opposite direc-ion. Just look at the beautiful illustrations given o the profession by Eisendrath of Chicago, exhibit-ng the great variety of anatomical relation between he cystic artery and the bile ducts, also the great ariety in the course of the cystic duct with regard o the common. No one can foretell whether any ne of the many anomalies is present in the case just t hand. A good exposure of the junction of the ystic and hepatic ducts will show clearly the fas-inating anatomical relations; it will also permit the urgeon to place the ligature close to the common luct and thus render absolutely impossible the re-ormation by nature of a smaller gallbladder after holecystectomy, which some surgeons claim to have bserved. Starting the excision of the gallbladder rom the fundus usually means more bleeding in the allbladder bed. It is quickly and easily controlled —best, to my mind—by an aseptic gauze tampon, hich during the operation is compressed by a blunt etractor held by the second assistant, and which ater on, together with the cigarette drain, that is ntroduced down near to the ligated cystic stump, is urrounded by a piece of rubber dam to prevent ad-esions. These three items form my way of drain-ge after cholecystectomy.

If, now, we place the patient in Sims's posture mmediately after he has reached the bed—or, better till when he is lifted from the operating table on he stretcher to be removed from the operating room nd wheeled back to his bed—the bottom of the small elvis after an operation for perforative appendicitis nd the cystic duct stump after cholecystectomy is the ighest point of the drainage system inaugurated nd not the lowest. Blood serum, wound secretion, ften also bile from the gallbladder bed or a leaking ystic stump, will now run down hill to the outside ver the shortest route possible, not uphill. I insist n the continuance of this posture for the first ghteen to twenty hours, when a slight turning of e body to the left is permitted. On the third day ter the operation the patient may permanently take e usual position on the back; that means at a time hen the principal normal wound secretion has ased. During these first few days the foot end the bed is not raised because we all like to avoid aving any wound secretions sag toward the sub-renic space from where absorption into the general circulation is favored. At the end of the third day the foot end of the bed is raised on blocks.

It is my belief that by looking ahead and always considering safety first to be the solemn duty of the surgeon, the majority of the patients will do well under this treatment after cholecystectomy. The statistics of many individual men nowadays show that of one hundred patients with interval operation for appendicitis and also for acute appendicitis—the latter being done within the first twelve to eighteen hours after the onset of the attack—one hundred get well. Similarly we see in one hundred cholecystectomies, ninety-eight patients (if not ninety-nine) recover. A death is usually due to an accident. I believe that drainage aided by Sims's posture, and later on by a slight Trendelenburg posture, if generally adopted, would contribute to make such results universal.

I proceed in exactly the same way if, in addition to cholecystectomy, the hepatic or common duct is to be drained, or if gallbladder and duct require drainage.

Another operation which in its immediate results is, I think, greatly benefited by Sims's posture is gastroenterostomy. In posterior gastroenterostomy I always join the short loop of the jejunum to the stomach in such a way that the current in both organs runs in the same direction. What is then more plausible immediately after a posterior gastroenterostomy than to turn the patient into a not too exaggerated right Sims's posture and at the same time to slightly raise the head of the bed? (Fig. 2). I know from experience that the patients like this position. Although later on in the aftertreatment I often repeat to them that they may well stay on the back, I find the majority of them favoring the right lateral posture. Certain it is, that I see very little if any vomiting after my gastroenterostomies. Whether or not this is partially due to the posture, I am not quite ready to decide, although I believe it is. An important contributing factor is that for years surgeons have practised the attaching of the stomach, and not of the jejunum, to the rent in the transverse mesocolon. The socalled and much dreaded vicious circle is no longer seen.

Remembering that a thrombosis of the left femoral vein—should it occur—makes its appearance not earlier than the second week following the operation, I never keep the head end of the bed on the blocks longer than up to the third day—at the utmost up to the fourth day—after the operation, the time peritoneal secretion ceases. The assistants and nurses know that by that time the blocks have to wander under the foot end of the bed.

I insist on continuing keeping the foot end of the bed raised until the patient gets up. As soon as he is allowed to be up and move about the blocks are removed and the normal horizontal position of the bed is resumed. I am never influenced by the requests of the patients to change these tactics. To questions of why I insist on the posture, I reply with the statement that I am willing to tell them when they are ready to leave the hospital. To many I have had to explain the why later on; others forget to ask about it again.

Only temporarily is it allowed to put the foot end of the bed down; that is, in those exceptional cases

where some difficulty is experienced in urinating when the foot end of the bed is raised; often the same patients are also unable to void in the horizontal posture, but some certainly can easier relieve themselves if the bed is lowered. To allow the bladder to distend as much as possible I have always found to be a splendid policy. In my division we defer the postoperative use of the catheter as long as possible, especially with the male, without, however, being too hard on the patient. I cannot agree with those surgeons who demand catheterization if the patient has not voided within eight to ten hours after operation. Now and then we could well temporize until thirty to thirty-six hours after operation, when the patient urinated spontaneously, and then passed only 350 to 400 c.c. Why use a catheter for such a small quantity, which frequently did not bother the patient to carry in his bladder in the midst of well being! After all, catheterization, no matter how carefully and how aseptically done, means for the patient—at least for the male patient—an additional interference which if avoidable means another asset for him.

I have before mentioned Sims's posture combined with a slight Fowler's or Trendelenburg's posture. I am much in favor of combining postures, and let the degree depend upon the amount of infection and extension of the intraperitoneal effusion. We all recognize the great service the late and much lamented John B. Murphy has done to suffering humanity with his systematic rectal instillation, the patient being in an exaggerated Fowler's posture, in cases of general septic peritonitis after intraabdominal perforation of any sort. Special beds, useful ones indeed, have been constructed to make this posture comfortable and practical. Usually we can get along with a simpler arrangement. In cases of this type, if we drain at the same time, I have for years been in the habit of combining Sims's with Fowler's posture. If the lower abdomen and small pelvis was found filled with infected fluid, particularly after perforation of a gangrenous appendix or gallbladder, a duodenal or gastric ulcer, the perforation in the latter occurring shortly after a meal, we make a stab intramuscularly in both groins, introduce through it a drain into the small pelvis and the respective lumbar region, and then turn the patient right upon his abdomen, at the same time raising the head end of the bed on the slightest blocks (Fig. 4). I feel sure that the convalescence and recovery of some of these patients has been greatly favored by this procedure.

In this connection I must still briefly discuss the claim that the right Sims's posture employed immediately after operation, with the patient slowly recovering from the anesthetic, favors the appearance of a postoperative pneumonia, which latter complication is so often seen affecting the right lung. I do not believe in the correctness of such an assumption. During all my experience, particularly in former years, I have kept old patients after suprapubic cystotomy or prostatectomy with drainage of bladder and prevesical space in the Sims's posture, without remembering to have seen pneumonia more readily appear in its wake. It is true the order given in these cases always has been to change the posture from right to left, or vice versa, every six to eight hours. However, it has often happened in the course of the first day that the patient desired to remain on his right side—provided this happened to be the first in which he had been placed—yet no pneumonitis was observed. On the contrary, if combined with early breathing exercises, beginning as soon as the patient comes out of the anesthetic, I think that only benefit will accrue from the arrangement which has been discussed.

As already mentioned, I have gone even a step further in the course of the last three years, commencing the Sims's posture immediately after operation, viz., while the patient is still in the operating room. In January, 1918 I did a posterior gastroenterostomy for duodenal ulcer on a private patient. The anesthetic was given by a specialist who is rightly considered an authority in this line not only in New York and our country, but the world over. On the trip from the operating room down the elevator to the respective floor of the private building, with the patient lying on his back on the stretcher, he vomited the bloody contents of his stomach so suddenly and in such quantity and evidently, unfortunately, coinciding with an inspiration, that even the usual, most careful vigilance of the accompanying anesthetist could not prevent the partial flooding of the trachea and upper bronchial tree. It required considerable continuous careful attendance before free respiration was restored, not to speak of the anxiety endured before we knew definitely that an aspiration pneumonia would not likely set in. Later, discussing this occurrence with the colleague in question, we came to the conclusion that it would certainly be best for the patients' interest if when they were being lifted from the operating table they were placed "immediately upon the stretcher wagon" in the Sims's posture, this to be continued in the bed. We felt that then aspiration of the stomach contents, however small in volume, could not occur, because everything regurgitated from the stomach would, on account of gravity, have to flow to and out of the lower angle of the mouth.

The same holds true for stomach lavage, postoperatively, in cases of acute dilatation as well as persistent vomiting, or, anteoperatively, as, for instance, in retroperistalsis due to intestinal obstruction. Here Sims's posture combined with a slight Trendelenburg posture is a most valuable preventive of aspiration into the lung.

To prove the correctness of the contention that immediate postoperative Sims's posture arranged on the stretcher at the time of the patient's return from the operation and then continued in bed does not favor the development of pneumonia, but will rather prevent it, I would mention that I have been told that one of our large city hospitals has adopted this posture immediately after operation as a routine and has since observed a great reduction in the occurrence of the muchdreaded postoperative pneumonitis.

I should like to continue on this most interesting subject. I have no doubt that many surgeons, here and abroad, have observed these measures to the advantage of their patients, as I have done for a great number of years. What I wanted to bring

it is, that methodical insistence on certain postures postoperative treatment will often enable us to void the eventual occurrence of serious complications.

"Prophylaxis, the prevention of disease, is the ghest aim of medicine."

Hypothyroidism, Affective Diseases, and Intestinal Autointoxication

GEORGE EDWARD BARNES, M.D.,
Herkimer, N. Y.

There are certain easily observed signs of hypothyroidism which apparently are not known. I have observed and wondered about these points for many years and about four years ago decided that they are due to hypothyroidism. They are roughness of the skin on the pointed extensor surfaces—elbows, knees, buttocks—dandruff, and grayish coating of the tongue.

It is well known, of course, that in hypothyroidism to a high degree the skin in general lacks in suppleness or smoothness. However, there are many cases in which the skin in general appears to be in good condition but in which careful observation will reveal that in the places mentioned it is more or less rough and scaly, the scalp more or less covered with dandruff, and the tongue more or less coated. These signs are of immense value in diagnosing the numerous cases of slight hypothyroidism and are particularly of value in the differential diagnosis of simple, diffuse colloid goitre. The metabolism test is a useful procedure and I do not wish to deprecate it, but, since it is impossible to control all variable factors in all cases, it seems to be, as has been said, of least value in those cases of slight goitre in which assistance is most needed. A glance at the elbows, knees, and tongue often greatly assists. Of course, other signs, notably the temperature, should be investigated.

Under the influence of a lack of thyroid secretion the epithelial cells on the dorsum of the tongue, as on the elbows, knees, and scalp, do not drop off as they should. They accumulate and this accumulation is assisted by the depressions between the large papillæ on the posterior part of the tongue. These masses of dead epithelium are kept moist by the saliva and are infected by the saprophytes in the mouth and consequently they decay and there result the grayish coating of the tongue and a fetid breath. There is a frequent cause of a bad breath. There has been and still is a general belief that such a coating of the tongue is caused by a disturbance in the stomach but there is no scientific ground for such a belief. I have examined and treated many hundreds of cases of digestive ailments but never once have I considered a coated tongue to be caused by any stomach condition (nor have I ever made a diagnosis of intestinal autointoxication). The stomach may be disturbed at the same time that the tongue is coated but that coexistence does not, of course, establish a causal relation.

Alopecia in early life is often a sign not only of hypothyroidism but also of an anteriorly causative pathetic effectivity (1, 2). Pathetic effectivity causes diminished activity of the thyroid gland and the insufficient thyroid secretion causes alopecia. And pathetic affectivity weakens the heart which therefore sends less blood to the scalp and the insufficient blood supply tends to cause alopecia.

The diagnosis and treatment of thyroid malfunction would be much facilitated by a thorough knowledge of affective diseases as set forth in my articles (1, 2, 3, 4, 5, 6, 7, 8, 9, 10). There is an intimate relation between emotional activities of the mind, the brain, and the functioning of the glands of internal secretion. Medical science has made a too limited application of this important fact. I wish to indicate a few points. What I have called pathetic affectivity, or what has been too restrictively called vagotonia, causes a hypofunction of the thyroid gland but what I have called violent affectivity, or what has been too restrictedly called sympathicotonia, causes a hyperfunction of the thyroid gland. It should be recognized that in the majority of cases it is not primarily the hypofunction or hyperfunction of the vagus nerve or the sympathetic nerves that causes symptoms but it is the fundamental prevailing emotional tone which first affects these nerves and through them causes symptoms. Furthermore, medical writers tend to attribute to the ductless glands effects which should primarily be attributed to affective (emotional) disturbances. Emotional activities and glandular activities are bound up together. The emotional disturbances, it should be more frequently recognized, very often primarily initiate the glandular disturbances. The confounding of the effects of these two interacting systems is not surprising because the same symptoms, for example, a slow heart action and relaxed bloodvessels, can be caused by pathetic affectivity and by hypofunction of the thyroid gland but in prevalent affective diseases, be it noted, the pathetic affectivity initiates hypofunction of the thyroid. Again, the same symptoms, for example rapid heart action and excessively contracted bloodvessels, can be caused by violent affectivity and by hyperfunction of the thyroid but in prevalent affective diseases the violent affectivity initiates the hyperfunction of the thyroid. Not only do the affective disturbances thus directly affect the activity of the glands of internal secretion but by directly affecting the blood supply to these glands they indirectly affect the activity of these glands. Primary diseases of the glands of internal secretion,

for instance cretinism, are recognized properly by medical science, and, by the way, it is true that primary disturbances in these glands affect the activity of the vegetative nervous system and even of the emotional activities, but medical science does not yet take sufficient cognizance of the tremendous importance of affective disturbances in causing disturbances in the glands of internal secretion.

It may be remarked that the same patient may at the same time have two forms of hypothyroidism, one from a primary and the other from a secondary disturbance, as one from colloid goitre and the other from the effects of pathetic affectivity.

Of all these affective glandular ailments, probably those numerous cases of neurocirculatory asthenia (3) (soldiers' irritable heart, effort syndrome), particularly the group which follows the ravages of pathetic affectivity, are the most puzzling. As the preceding pathetic affectivity, causing the hypofunction of the thyroid, subsided, there welled up in these cases a manifestation of the opposite variety of affectivity, violent affectivity, and there naturally appeared in consequence an increase in the function of the thyroid gland (and of the adrenals). A somewhat different view of these phenomena may be expressed by saying that as the pathetic affectivity wore off its depressing effects on the thyroid gland (and adrenals) diminished and in consequence of this diminution of depression the thyroid (and adrenals) increased in activity. Which of these two statements may be the more correct, that is, whether the increase of function of the thyroid (and adrenals) results primarily and chiefly from the stimulation of violent affectivity which naturally wells up on the diminution of pathetic affectivity or whether it results primarily and chiefly directly on account of the diminution of pathetic affectivity I cannot say but I think both processes take place, probably in different degrees in different cases.

However, that the former is usually the more active would seem to be indicated as a case of hypothyroidism arising from combined colloid goitre and pathetic affectivity may present the most severe symptoms of neurocirculatory asthenia. It would seem that a thyroid gland that is acting weakly on account of the goitre would not become so very active on the cessation of pathetic affectivity unless a current of violent affectivity stimulated it. On account of the persistence of some of the effects of the preceding pathetic affectivity and its accompanying hypothyroidism and on account of the present violent affectivity and its stimulating effect on the thyroid, there exists in neurocirculatory asthenia the seemingly paradoxical condition in which there are some outstanding symptoms of hyperthyroidism coexisting with more obscure symptoms of hypothyroidism. A familiarity with these numerous cases will be of remarkable assistance in recognizing them. The symptoms are of great importance for this purpose. The temperature is apt to be subnormal. Whether the skin in the places already mentioned is rough and the tongue coated depends on the severity of the preceding siege of pathetic affectivity and on the degree to which the thyroid was depressed by it. The heart action is fast, the arteries excessively contracted, and the pulse pressure low. The history of these cases, which, by the way, is often difficult to elicit unless one is familiar with the ailment, is also of value in directing one to a correct diagnosis. Many people suffer more or less with neurocirculatory asthenia also after severe sicknesses and after long etherizations. As their weakness wears off two activities, affective and glandular, tend to appear: violent affectivity bounds up and thyroid (and adrenal) activity increases. In neurocirculatory asthenia, then, there is hypothyroidism in the sense that the thyroid is less active than it would be if the patient were in perfect health but there is hyperthyroidism in the sense that the thyroid often produces more secretion than the patient in his weakened condition needs. So, it may be well said that hypothyroidism should not be regarded as an absolute term measured by the activity of glands in health. An apparent hypothyroidism may be for the individual patient an actual hyperthyroidism and this fact is a strong example of the fact that medical practice after all deals with individuals in the last analysis.

As might be expected from the preceding facts, patients having neurocirculatory asthenia are often hypersensitive to the administration of thyroid extract, iodine, epinephrin, and cocaine. The alarming condition which appears from time to time after the use of cocaine and adrenalin in operations undoubtedly appears in these hypersensitive cases of neurocirculatory asthenia, chiefly on account of the resulting contraction of the arteries. Of course, the ailment when possible should be recognized and these drugs not used. In such cases, not only these drugs but also the ever present violent affectivity produce these alarming conditions. Indeed, the emotional disturbance aroused by mere conversation about the patient's disease or a contemplated method of treatment, especially an operation, sometimes brings on astonishing symptoms, as vomiting and fainting. These and particularly slighter disturbances from the same cause, e.g., lightheadedness or headache and nausea, are often credited to bilious attacks and intestinal autointoxication!

If the thousands of doctors of medicine who are still making diagnoses of intestinal autointoxication and bilious attacks will only obtain a thorough practical knowledge of affective diseases and digestive, and, indeed, abdominal diseases there will be an immense increase in the good done by the practice of medicine and multitudes of ailing people will no longer patronize all sorts of quackery. Then most of those who now say that there is nothing to my ideas on affective diseases will use these ideas in most of their cases! It rests with present practitioners of medicine whether they will make themselves able to give to their patients the benefits of a knowledge of affective diseases or whether the people must wait until the medical colleges have taught these things to the rising generations of doctors. It must be evident that the sooner medical men understand affective diseases and people get the benefit of this knowledge the better it will be for all concerned. May it not be said that this knowledge introduces a new era in the practice of medicine?

I hope that the devotees of intestinal autointoxication will read at once not only my articles listed below, particularly the first six, but also the pertinent articles by W. C. Alvarez (11), and A. N. Donaldson (12).

Since 1913 many causes have been assigned to asthma, particularly nasal obstruction, protein sensitization, and focal infections. That many varied methods of treatment bring relief to many of these patients seems to me to be due not to specificity in the treatments but to the effects of the treatments in allaying the pathetic affectivity either by removing the annoying cause or by suggestion. Anything which arouses pathetic affectivity can cause asthma in people whose neurobronchial apparatus is susceptible. Possibly there are other causes. However, although I have not had many cases of asthma, in all that I have had affective disturbance has been the cause. It sometimes takes much questioning to find the disturbing experience. I now have an asthmatic from a neighboring city who had had the disease six years. He developed it after much worry over the fact that a man his junior had been put ahead of him. He is now free from asthma.

It was with considerable hesitation that I included hay fever among affective diseases. If pollen sensitization had been known in 1913 I question whether I would have included it. However, it still looks as if some disturbing pathetic affectivity is at the bottom of the disease. In 1922 I had a patient who had had very severe attacks of hay fever for several years but who had never had the disease until strong pathetic affectivity weakened her almost to nervous prostration. So far as protein sensitization is concerned both in asthma and in hay fever it may be that such sensitization is made possible through the effects of pathetic affectivity acting on the vegetative nervous system. Its symptoms would indicate that. I think someone has already suggested that protein sensitization may be caused by some change in the nervous system.

As the indications for medicinal treatment of simple, colloid goitres are very distinct I wish to express objection to faddish methods of medicinal treatment and no medicinal treatment and to operative treatment in these cases. Removal of part of such an enlarged hypofunctioning gland deprives the patient of valuable tissue which can never be restored in function or in substance.

I wish to take this opportunity to elucidate a slight matter in my article on high blood pressure, arterial hypertension, and arteriosclerosis (5). In it I refuted the claim made by some medical authors that the germs and toxins from focal infections *directly* cause arteriosclerosis, but I did hold that these toxins act on the vegetative nervous system which in turn causes an abnormal activity in the muscular layers of the arterial walls thereby giving rise to pathological conditions in the arterial walls. When I denied that germ toxins from localized infections cause arteriosclerosis I merely denied the *actual claim* made by the authors that these toxins *directly* act on the arterial walls and cause arteriosclerosis but if my article is carefully read it will be very evident that I hold that toxins first affect the activity of the vegetative nervous system and that they thus do act *indirectly* as one cause of arteriosclerosis.

I wish to make a plea to medical people that they make a thorough study of affective diseases. I know of many doctors who deny the existence of these diseases, which constitute fully half of the cases that the general practitioner treats! Supposedly learned physicians, some of whom are even themselves filled with pathological affectivity, repeatedly refuse to accept my ideas, their disapproval being expressed sometimes with thoughtless ease, sometimes with supercilious disdain, and sometimes with violent rage! A most strange situation! I have prepared and freely presented for the advancement of medical science, the advantage of doctors of medicine, and the welfare of sick humanity, facts of the very greatest scientific value and the profession has in large measure rewarded me with disdain and insult. Most of these affective diseases are wrongly diagnosed and treated as intestinal autointoxication, bilious atacks, and uric acid diathesis. It is passing strange that these utter humbugs could so long find lodgment with medical practitioners. I prescribe for them a much greater knowledge of digestive, in fact, of abdominal, diseases and of affective diseases. Beginning over twenty years ago, I have diagnosed and treated hundreds of cases of digestive ailments and I have never once made a diagnosis of that product of the imagination called intestinal autointoxication but I have hundreds of times made a diagnosis of affective diseases. Indeed, it was in the clinics for digestive ailments where, about twenty years ago, I worked out in an absolutely original way my ideas on affective diseases. The first observation that I made was that, as I held my finger on the patient's radial artery, the artery occasionally contracted and dilated according to the effect of the conversation on her emotions. I soon observed that the arteries of patients were continuously and habitually excessively contracted or relaxed according to the prevailing emotional condition. I further observed that the state of contractility of the heart and bowels was also thus affected, etc. Strong emotions, especially if continued, leave a deep impression and effect on the nervous system, and both of their own persistence in modified form and by the persistent action of the deeply sensitized vegetative nervous system, cause for a long time disturbed function in the body's organs.

Paresis of Duodenum, Stagnation and Consequent Toxicity of Duodenal Contents a Frequent Cause of Death in Surgical Operations on the Upper Right Abdominal Quadrant*

Preliminary Report

A. L. SORESI, M.D.,

New York

Some patients who have undergone operations on organs of the right upper abdominal quadrant, especially on the stomach, fare well for three or four days, then the pulse becomes irregular, more frequent and small, the temperature becomes subnormal, and the skin clammy and covered with cold perspiration. Notwithstanding any and all therapeutic measures the patient passes away on the fifth or sixth day. We take into consideration only the cases where leakage did not occur, where neither peritonitis, intestinal obstruction, nor ileus were present. In short, that class of patients who make the surgeon feel that the operation was very successful, but for some unknown reason the patient died. We shall not discuss here any of the numerous theories and reasons offered as an explanation of death occurring under the circumstances mentioned above. In this preliminary note we shall only state that death is due to absorption of toxic material, which collects and stagnates in the duodenum. This toxic material collects in the duodenum because the duodenum itself becomes paretic and does not discharge its contents in the lower bowels. Death is due to the same mechanism and occurs under the same circumstances as it does in partial or complete obstruction of the duodenum, although the duodenum is patent.

Without even taking into consideration, at present, the factors which aggravate obstruction of the duodenum, such as trauma, infection, and impaired blood supply, we shall accept as proved the notion, supported by clinical and experimental data, that obstruction of the duodenum is an extremely serious condition. The question which must be answered is, therefore: Do we have obstruction of the duodenum or a condition similar to it after operation on the stomach and other organs of the right upper quadrant? Our answer, supported by clinical and experimental irrefutable proofs, is: We have a condition similar to duodenal obstruction, that is collection, stagnation and absorption of toxic duodenal contents.

CLINICAL CASES

In the last six months I have lost two patients, both having undergone gastrectomies for carcinoma of the pars pylorica. Both patients presented symptoms strikingly similar and commonly observed in this class of patients. Briefly, both patients were relieved of the usual stomach distention, during the second and third days following operation, by gastric lavage. No fluid was allowed by mouth and 1,500 and 2,000 c. c. was given daily either by rectum or by hypodermoclysis.

Pulse rate was 98 to a maximum of 120, regular and of good quality: temperature 100°, the afternoon of the day of operation, kept constantly around 99—to be exact, 99.4, 99.2, 99; respirations around 20. Abdomen was soft, not distended, on the contrary scaphoid. The patients were comfortable, only begging for a drink. On the fourth day, fluids (water, milk and coffee) were allowed by mouth, greatly enjoyed and retained: the patients, however, were rather restless. The pulse began to become irregular, intermittent, going as low as 70: temperature 99°, 98°, 97°, 99°; respirations 25. During the night the restlessness increased. On the fifth day, the patients were more restless, begging to be put to sleep. Warm coffee, with milk and water, were given at will; temperature 98°, 97°, 97°, with cold clammy perspiration; pulse irregular, intermittent, small, respirations fatigued and irregular.

The condition became progressively worse until one patient passed away in the evening and the other during the early morning. In both patients the usual therapeutics were applied. Following the advice of the attending physician, Dr. J. Steele, caffeine was used as heart stimulant, morphine one sixth grain was administered twice to one patient and three times to the other. To one patient 600 c. c. of whole blood were transfused on the noon of the fifth day. One patient had a bowel movement on the fourth day, and another just before death; the other patient had a movement only just before death.

The outstanding features of these cases were: abdomens were soft, tractable, not distended, but, on the contrary, scaphoid to the very end; from the third day to the end the patients wasted very rapidly, one could notice them getting thinner every hour. Notwithstanding the fact that they were drinking freely, that all therapeutic means were promptly applied, the patients passed away with subnormal temperatures, as if completely exhausted.

The symptoms preceding death could evidently not be attributed either to leakage, peritonitis, ileus or intestinal obstruction. To me they seemed similar to the ones observed in obstruction of the duodenum. To prove whether this view was correct or not experimental work was immediately undertaken.

EXPERIMENTAL WORK

Six dogs were operated upon by performing gastrectomies, according to different standard methods. Three days after, that is, at the period corresponding to the period in which patients presented the symptoms described above, the animals were etherized and while still alive the abdominal cavity was examined. Healing was proceeding normally, there was no blood, pus or any other fluid; the stomach was more or less distended; in all the animals the duodenum was found more or less distended, paretic, full of a chocolate colored fluid, although, according to the

*From the Department of Surgical Research, New York Homeopathic Medical College and Flower Hospital.

type of operation performed, there was no physical obstacle to the passage of this fluid either into the stomach and thence into the jejunum or directly into the jejunum. The first portion of the jejunum was also somewhat congested and distended. While we shall study thoroughly the contents of the stomach, duodenum and jejunum at various intervals, after the operation, at the present it is sufficient to emphasize the fact that the duodenum was more or less distended, paretic and contained a great amount of chocolate colored fluid. This finding means that in all the animals a condition existed similar to that found when obstruction of the duodenum is present. Indeed the first phenomenon following obstruction of the duodenum is a collection of fluid in the duodenum itself, because obviously this fluid cannot be evacuated. The fluid which collects in the duodenum is composed of bile, pancreatic juice and secretions from the mucosa, and its glands. This fluid is not toxic *per se,* it becomes toxic because it stagnates in the duodenum through a process which is not fully understood yet. One incontrovertible fact is, however, that the duodenal contents become strongly toxic because it stagnates in the duodenum itself. Between duodenal obstruction and the condition which follows gastrectomy and other operations on the upper right abdominal quadrant, the only difference is the mechanism which causes stagnation of the duodenal contents. In obstruction it is the physical obstacle created by the obstructing agent; in the cases under consideration, it is paresis of the duodenum. It is easily understood how paresis of the duodenum will occur when the duodenum is severed from the stomach or is otherwise severely traumatized, or the stomach itself becomes paretic, as evidenced by the enormous amount of fluid, which may collect in it, even after a simple gastroenterostomy. As there is no doubt that in our experimental animals the secretions normally passing through the duodenum, instead of passing through it, stagnated there, we feel justified in asserting that in the cases under consideration death was due to collection, stagnation and consequent absorption of toxic duodenal contents. The contents become toxic and are absorbed following the same process which causes their toxicity and absorption in duodenal obstruction. In passing, we may remark that collection and stagnation of duodenal contents are favored by gravity, on account of the peculiar shape and location of the duodenum itself and the position held by the patient lying on his back in bed.

Exceptionally, experimental animals and fortunately few patients die from absorption of toxic stagnant duodenal contents. The importance of this factor in causing death, however, is positive and while we shall not discuss in this preliminary report the mechanism that causes paresis of the duodenum and how duodenal peristalsis is again resumed, we think we have made the point clear that death is due to paresis of the duodenum, causing collection, stagnation, toxicity and consequent absorption of duodenal contents. When we take into consideration the fact that patients undergoing severe operations on organs of the right upper quadrant are usually in a poor general condition, it is not surprising that absorption of the toxic duodenal contents turns the tables against them.

We are at present engaged in a thorough study of this subject in order to devise therapeutic means which will help in these cases. The work already accomplished gives great promise that means adequate to meet the needs of this class of patients will shortly be available and confirm the view expressed above that death is due, in the cases under consideration, to paresis of the duodenum causing collection, stagnation, consequent toxicity and absorption of the duodenal contents.

Late Metastasis of Melanosarcoma of the Liver*

MAX J. SCHROEDER, M.D.,
New York, N. Y.
Instructor in Gastroenterology at the New York Post-Graduate Medical School and Hospital

There is an existing impression that melanosarcoma metastasizes quickly. This idea is erroneous and will mislead in making a correct diagnosis. The case reported is an interesting one from the viewpoint of late metastasis.

Case.—N. A., forty-one years of age, operator on ladies' waists, presented himself on June 5, 1922, giving the following history: He was married seventeen years ago, had one child living and two had died in infancy; wife was pregnant. He smoked a good deal, rarely drank alcohol, but drank from two to four cups of coffee daily. Family history was negative. His health had generally been good. He had had none of the diseases of childhood, and there was no history of pneumonia, typhoid fever or rheumatism. He rarely complained of headache. His right eye had been removed on March 10, 1916; the left gave no trouble. He complained of a good deal of cough, and was often conscious of his heart beating. Bowels were regular, appetite good, and he denied venereal disease in name and symptoms. Two weeks

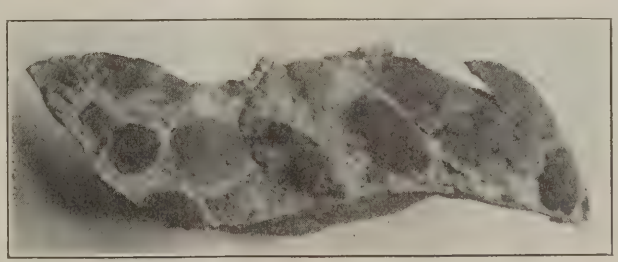

Fig. 1.—Cross section of the liver showing circumscribed area of melanin containing pigment.

*Read before the Clinical Society of the New York Post-Graduate Medical School and Hospital, January 19, 1923.

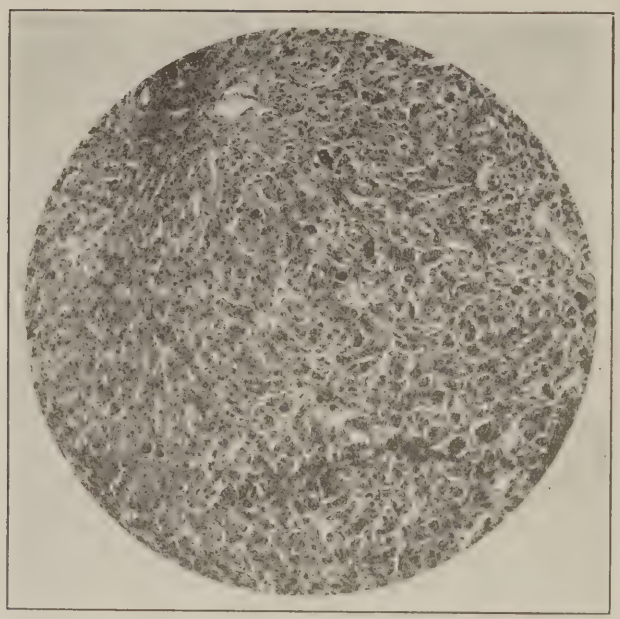

Fig. 2.—High power of the liver showing liver cells encroached upon by melanin pigment granules.

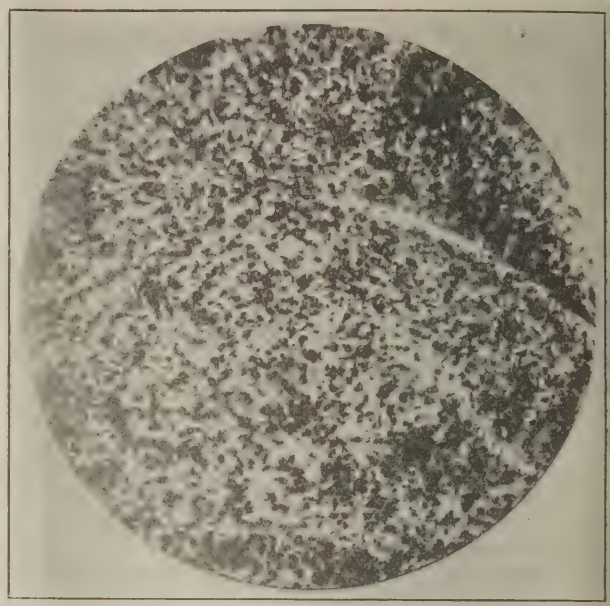

Fig. 5.—Low power of section of the tumor of the eye showing melanin pigment granules.

before presenting himself for examination he was seized with a cramplike pain in the epigastrium and right hypochondrium radiating to the kidney area and right shoulder.

Physical examination.—This showed a fairly well developed male, scalp, ear and nose negative, right eye missing, left eye reacting to light and accommodation. Sclera had icteric tinge, many teeth were missing, and the remainder were carious. There were no visible pulsations in the neck, no enlarged glands or masses of any kind. Heart sounds were regular, slight systolic murmur heard, right border not displaced. Liver, anteriorly, dullness extended from the fourth intercostal space in the right nipple line to the sixth intercostal space in the midaxilla, just above the breath sounds were diminished and medium moist râles were heard. Posteriorly on the right side of the chest there was dullness to flatness from the angle of the scapula down and diminished breath sounds as well as vocal resonance. In the abdomen the liver extended eight centimetres below the costal margin in the right nipple line, to a point four centimetres below the costal margin in the left nipple line, edges meeting the costal margin in the left midaxilla. Spleen was not palpable.

Laboratory findings.—Blood count revealed 6,000 leucocytes; differential count of fifty-six per cent. polymorphonuclear neutrophiles, twenty-six per cent. large lymphocytes, seventeen per cent. small lymphocytes, and one per cent. eosinophiles. Hemoglobin was eighty-five per cent. Chemical blood showed 463 NaCl, .122 sugar. Temperature fluctuated between 98.1° and 101.8°. No parasites, occult blood or mucous in the feces. Specific gravity of urine was 1.019, faint trace of albumin, sugar negative, casts negative. Blood Wassermann was negative.

X ray findings showed a small gastric residue in the pylorus at the end of six hours. Displacement of the bulbus of the left, by what appeared to be increased size of the liver. There was colonic hypomobility, and the right dome of the diaphragm appears roughened and high.

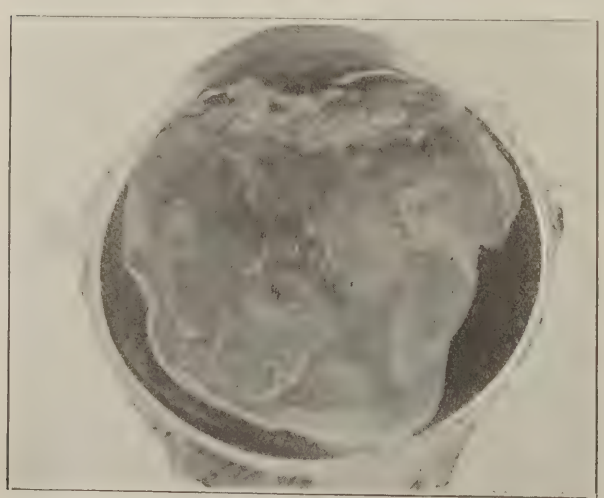

Fig. 3.—Cross section of the eye with membrane covering tumor.

Fig. 4.—Cross section of the eye showing membrane removed exposing tumor.

Course of the disease.—To sum up the things of interest, we must note the enlarged liver, the fever, negative blood count, chemical blood as well as blood Wassermann; the x ray corroborating the physical findings as regards the enlarged liver; the abdomen, especially in the upper part, was becoming fuller, the distention being rather conspicuous. The patient was growing dyspneic due to encroachment upon the chest. Laparotomy was indicated and was performed on June 29, 1922, by Dr. Charles Gordon Heyd, who was kind enough to submit the following report:

At operation the liver was found to be about three times the normal size, uniformly enlarged, with enlargement having taken place in the right and left lobes. The surface of the liver appeared like a mass of blueberries, with patches of normal liver between them. The liver was the seat of diffusely implanted neoplasms, each one discrete, being about the size of blueberries and having a peculiar blue black melanotic appearance. The abdomen contained about 800 c. c. of free fluid. Remainder of abdomen was negative. The operation consisted of laparotomy with removal of a portion of the liver for microscopic examination.

Microscopic examination.—Dr. Louise H. Meeker examined the specimen and reported as follows:

The dark areas described in the gross are fairly well circumscribed. They consist of densely packed polymorphous cells, varying greatly in size. Some of the cells are rounded and some are spindleshaped and all contain more or less dark brown pigment granules. The granules are apparently melanin. A few cells are of giant size with several nuclei. The borders of the melanin containing areas show the new growth cells extending into practically unaffected areas of liver cells. A few cells are found diffusely throughout the liver cords. The melanin containing cells seem collected chiefly about the central veins, from which they extend outward and compress the adjacent tissue. The cells suggest similar tumors found in the choroid coat of the eye. There is some increase of fibrous tissue, congestion and round cell infiltration in the liver tissue bordering the circumscribed nodules.

Diagnosis.—Melanosarcoma.

Hospital report.—The following report was received from the Herman Knapp Memorial Eye Hospital: History of patient N. A., as taken March 9, 1916: Eight weeks ago patient noticed poor vision and could not distinguish colors. There was no pain. He went to the Thirteenth Street Dispensary and was given eye drops. Later enucleation was advised. Vision was failing rapidly. Examination showed:

$$\text{Vision: } R\frac{20}{70}\ L\frac{20}{-}$$

R Pupil slightly dilated, did not react, tension normal, media clear, disc showed fairly large detachment, rather circular in shape, margins quite sharply marked off. Situated above and temporally to disc. Transillumination showed dark over detached area. *L* Normal.

Diagnosis.—Sarcoma of choroid, right eye. Enucleation was performed and the patient discharged on March 13, 1916.

Differential diagnosis.—The most important thing we have to contend with is an apparently enlarged liver, encroaching upon the right chest above and extending below into the upper part of the abdomen well below the costal margin on the right as well as the left side.

It appears to me that from a careful analysis of the various causes of enlarged liver we can gain more information than from all the laboratory data available. I therefore decided to review the various causes for enlarged and palpable liver, and to divide them into: 1, chemical; 2, mechanical; 3, bacterial; 4, parasitic; 5, secondary to the various systems; 6, due to anatomical position; 7, anomaly of the liver itself; 8, new growth.

I will admit that the classification given above is on no firm footing, for instance, Hanot's cirrhosis I placed under hemopoietic disease, whereas the true cause of it is actually unknown.

Bacterial causes are placed under causes due to anatomical position. This is simply an attempt to arrive at a schematic classification of the great number of causes of palpable and enlarged liver so that they may be at the clinician's command.

LITERATURE

It will be remembered from the history of the case that the eye was removed more than six years ago. The association of the removal of the eye and the now enlarged liver is surely sufficient to make one suspect melanosarcoma of the liver. This, however, was altogether overlooked, to the extent of leaving out the urinary melanin test, on account of the erroneous impression that melanosarcoma metastasized rapidly. Turning to the literature for reported cases, one is certainly impressed with the fallacy of that supposition.

It is true, Humphrey David Rolleston (1), who was a close observer of affections of the liver, is authority for the statement that recurrence of the liver usually occurs within three years of the appearance of the primary growths.

However, Charles H. Lilley (2) reports a case where the eye was removed ten years before the patient complained of gastric distress, the cause of which turned out to be melanosarcoma of the liver.

Jonathan Hutchinson, Jr., cites a case where first evidence of metastasis appeared eleven years after the diseased globe of the eye had been removed.

Larobaugh (3) reports a case of melanosarcoma of the liver seventeen years after the removal of the eye for melanosarcoma.

William H. Wilder (4) reports a case where metastasis in the liver occurred thirty-two years after the removal of the eye for melanosarcoma.

COMMENT

The lesson learned from this case and the literature of other cases: There is practically no limit to the length of time metastasis is liable to occur after the first appearance of the melanosarcoma of the eye.

Practical Therapeutics

VACCINE TREATMENT IN PRURITUS ANI, VULVÆ AND SCROTI*

J. F. MONTAGUE, M.D.
New York

To the general practitioner, or for that matter to the entire medical profession, the most interesting topic in a discussion of this disease is its successful treatment and cure. And a most natural interest it is, for if there be one disease that fills the physician with as much despair as it fills the patient with desperation, it is certainly pruritus ani, vulvæ or scroti.

The legion of remedies and cures flaunted in medical literature is proof that not one of them is of general value and that although it may relieve a case here and there it is not a cure in the true sense of the word. When we see patients who suffer as long as ten or twenty years, sampling, as they suffer, the thousand and one socalled cures known to the general medical profession, we cannot reasonably come to any other conclusion than that they are quite ineffective from the viewpoint of true curative ability.

The patient is in an ugly state of mind—his request is so simple and modest: "Stop this awful itching, doctor," and yet with the best professional acumen the physician can do nothing, but in truly empirical style try something else. It is, indeed, in the treatment of this disease that the high point of empiricism is reached, not only by charlatans but unfortunately by some of the most highly reputed medical men. Textbooks on rectal diseases, gynecological and genitourinary diseases in speaking of the treatment of this disease, say, "treat the cause" —and then give a list of nearly a hundred causes. Why would not the general practitioner despair?

Certain it is that there are cures without number. I myself have gleaned from literature and tried out over four hundred formulæ which are mentioned as cures of this disease in many otherwise accurate textbooks on rectal disease. But the general practitioner reading these lines will agree with me when I say, mildly, that they do not cure. There are some, which exert a palliative influence or perhaps remove some dominant feature of irritation and so effect relief, but the majority of such cures are temporary and evade the issue of a real cure.

The inefficacy of the methods in vogue is to my mind a selfevident proposition. When I consider the aforementioned patients who have come to me after suffering ten or twenty years and in one case in my practice, forty years, and reflect upon the numerous physicians who have treated these people during this time, I can come to no other conclusion.

Perhaps the falsely apparent simplicity of this condition leads the busy doctor to treat it without the solemn consideration he would give almost any other disease and without a due consideration of the causative factors in its production. Of course, some blame belongs to the patient who loses courage after one or two visits to a doctor and drifts off before the doctor has an opportunity to study his particular case. For these cases are perhaps more than any other disease, problems unto themselves.

But to come now to the matter of direct importance; namely, treatment of these cases, I wish to draw the reader's attention to a classification which has proved invaluable to me in the successful treatment of these cases. This has been elaborately set forth in my previous articles and my monograph mentioned in the bibliography. I will therefore state the matter briefly:

There are two distinct types of localized pruritus: one in which the itching is a misreferred sensation with visceral pathology as a basis—this I term an indirect pruritus—the other in which the itching is a correctly referred sensation, with pathological causes in the pruritic zone. This I term a direct pruritus. From the viewpoint of curative treatment this distinction is important, as must be quite evident.

A common factor to both types, however, is the fact that the itching and its consequences are both localized to the same area. By consequences I mean not only the mechanical injuries suffered by the skin of this area as a consequence of attempts at relief but also the infection that occurs in a definite proportion of cases and which is likely to occur in any of them. My researches into the causative organism in such infection appear to have definitely fixed the guilt upon two organisms.

To state concisely my views as to the suitability of vaccine therapy in these cases, I wish to draw attention to the following chain of facts:

1. My pathological studies support the idea that in a certain percentage of cases bacterial invasion does occur.

2. The only organism which I have been able to demonstrate in situ in the tissues is the staphylococcus.

3. The organisms which I have been able to culture directly from tissue excised from the pruritic area have been the Baccilus coli from the deeper layers of the tissue, and the Bacillus coli and Staphylococcus albus from the superficial layers of the tissue.

4. The fact that I have not been able to demonstrate the Baccilus coli in situ in the deeper tissues does not negative its existence there but rests upon a difficulty in staining this gram negative organism among tissues which in themselves take a gram negative stain.

5. In all the cases I have seen where sections taken from them showed a dermatitis of presumable infective origin, and which gave positive cultures from the deeper layers of the skin, erosions, abrasions, or maceration of the skin in this area were clinically present.

6. In view of the coincidence of clinical evidence that the natural barrier to infection has been weakened and the histological and bacteriological evidence that infection occurs in these cases, it seems logical to

*From the rectal clinic at the University and Bellevue Hospital Medical College.

conclude that in cases presenting such clinical evidence infection is either present or imminent.

7. In pursuance of this line of thought vaccine therapy seems indicated in that type of case which presents the lesions described.

8. The only vaccines that would appear appropriate in view of the aforementioned data are those of Baccilus coli and Staphylococcus albus.

In my experience with the treatment of pruritus of the perineum I have met with most excellent results in selected cases by the combined use of Bacillus coli and Staphylococcus vaccine. I have not, as yet, sufficiently formulated my data on treatment to give the definite percentage of cases in which I have successfully used it, but I will say at this time that the proportion of cases in which vaccine therapy is applicable as a curative measure is decidedly less than is commonly supposed, and by no means approximates one hundred per cent. It may, of course, be used as a prophylactic measure in every case.

I do not believe that vaccines, unaided by other measures, will cure an infective case, but they certainly do aid in the palliation of the pruritus pending the eradication of the infective focus and contribute much to the eventual cure by helping in the interruption of the vicious cycle of itching causing scratching and scratching increasing the itching. It is highly desirable that the physician should regard vaccines in general as an aid and not a substitute for procedures directed at the destruction of an infective focus. The latter should not be delayed because of attempted vaccine therapy.

If then we select our cases properly, i. e., those in which by the presence of excoriations or erosions we can safely assume the presence or imminence of infection, we may be certain of gratifying results. The following paragraphs describe the method I use and advocate in the treatment of cases which have been selected as suitable for vaccine therapy.

SELECTION OF VACCINE

Although there are some differences between the vaccines I use and the ordinary stock vaccine they concern the bacteriologist more than the clinician. I will therefore omit details of such procedure. Staphylococcus albus stock vaccine and Baccilus stock vaccine have yielded better results than any other vaccines, that I have tried. The idea of making an autogenous vaccine from smears taken from the surface of the pruritic zone is not consistent either with established bacteriological technic or with my findings as described in the chapter on bacteriology. If we are to obtain any result at all from the use of vaccine, I am convinced that a stock vaccine will serve the purpose. I start treatment with staphylococcus albus stock vaccine, and if response is not evident by the third injection commence Baccilus coli vaccine in addition.

DOSES AND CONTROL

A small dose at the start with a gradually ascending amount until a distinct reaction occurs, appears to be the best method of arranging the doses. When a distinct reaction, either focal or systemic, has been obtained it is well to note the amount necessary to produce this and consider it the normal maximum dose for the individual. This differs, of course, among individuals. From this normal maximum dose all administration of vaccine from that point on is based on this known figure controlling variations by noting the reactions produced.

FREQUENCY

The vaccine may be given from one to three days apart, but my own experience favors a two day interval. I continue treatment while taking other measures, such as ionic medication or topical application, to eradicate the infective focus. In some cases relief is rapid, and if properly selected all cases show a distinct palliation after the first two or three treatments. Vaccine therapy, depending as it does upon the evocation of immune response on the part of the body, demands a reasonable length of time in which to allow these processes to occur. Likewise, it should be continued for four to six weeks after the primary palliation.

TECHNIC

The preferable method of administering vaccine is by subcutaneous injection through a small gauge needle into the buttock, arm or adipose tissue of the abdomen. The other methods available are intramuscular or intravenous, but they possess many dangers, not involved in the above method and no advantages of therapeutic value. Protection against these organisms by the evocation of immune reactions, i. e., by the use of vaccines therefore is most logical not only in cases actually suffering from such bacterial invasion but also those who by their scratching will eventually weaken or remove the normal barrier to such infection, i. e., by abrading the skin.

Proceeding from the sound basis of accurate knowledge of the cause, the logical cure can be accomplished, for with a thorough understanding of the conditions existing, treatment becomes less of a problem and more of a definite task.

540 Park Avenue.

Vincent's Angina and Its Treatment.—J. Puig (*Presse médicale*, May 3, 1924) points out that the combination of spirochetes and fusiform bacilli studied by Vincent may occur not only in Vincent's angina but in any other condition manifested in necrosis of tissues. The germs are inoculable only in tissues in which the resisting powers have been weakened by injury or other harmful factors. The distinct rôle played in this connection by lack of vitamines account for the pseudoepidemics of Vincent's angina occurring among agglomerations of human subjects living on a scanty or too uniform diet. In five per cent. of cases the diminished resisting power of the mucosa is due to a general disease or lack of vitamines, but in ninety-five per cent. it is due to disturbances relating to the six year teeth or the wisdom teeth, such as infection of the pericoronary mucosa or chronic alveolodental irritation. X ray examination is of service in the study of the teeth in this disorder. Arsphenamine frequently heals the ulcerations; but it does relieve the lessened tissue resistance, and recurrence may take place. The only logical treatment, therefore, is to remove the underlying cause of the lessened tissue resistance.

Historical Medicine

Samuel Thomson and a Prethomsonian

THE HONORABLE WILLIAM RENWICK RIDDELL,
LL.D., F.B.S., Edin., F.R.S.C.,
Toronto

Samuel Thomson, self styled Doctor, and styled (as he says) by the Regular Profession, Quack, Empiric, the Sweating Doctor, the Indian Doctor, the old Wizard, The Steaming Doctor, and other like delectable epithets, is well known as the founder of a School of Medicine on this Continent in the early years of the last century (1).

One of his cardinal principles was that Providence had given to this region of the world a supply and variety of plants which if rightly discriminated and used, would heal all its diseases (2). He seems to have been a truly religious man: for conscientious reasons and thorough conviction, he left his original church, the Baptist, and became a Universalist.

Of little education, he "took nature for my guide and experience as my instructor" with the result that he arrived at the conclusion that "There cannot be the least doubt, but there is medicine enough grown in our country to answer all the purposes necessary in curing every disease incident to the climate if the people had a knowledge of it; but the doctors have so much influence in society and manage their affairs with so much art for their own profit and praise that the common people are kept back from a knowledge of what is of the utmost importance for them to know" (3).

He tells us that a very few of the doctors were fairly reasonable—for example "the famous Dr. Kittredge of Walpole" who was admired "on account of his extraordinary skill in surgery and the great name he acquired and justly deserved . . ."; but then "His system of practice was peculiarly his own, and all the medicines he used, were prepared by himself from the roots and herbs of our own country" (4). Then there was Dr. Barton of Philadelphia who agreed to try some of Thomson's medicine, but unfortunately died before he could report results—he "acknowledged that there was no art or science so uncultivated as that of medicine" (5). Then, too, there were Dr. Shephard, who befriended him when charged with murdering young Ezra Lovett, and Dr. Fuller, of Milford, N. H., who "made many statements in my favour as to the value of the medicine," (6) and one or two others.

But most of them were *mauvais sujets,* and did not hesitate to charge the innovator with murdering his patients, and to make the like unkind statements about him. They got what was coming to them. Dr. French who instigated the prosecution for murder and probably incited the witnesses to tell of medicines that Thomson called *coffee, bulldog, ramcats, screw auger, belly-my-gristle, etc.*—Dr. French got his deserts; "within a year he was brought to the same bar . . . and convicted of robbing a graveyard of a dead body which it is reported he sold for sixty dollars—he lost all his credit and was obliged to quit his country" (7).

So, too, of "the five doctors at Eastport, when I went there, who had plenty of business . . . in a short time three . . . had to leave the place for want of employment" (8).

And others, beside the archenemy, Dr. French, who took part against him, came to grief. "Deacon Pecker, one of the Grand Jury that found a Bill against me, . . . shortly after I was put in prison . . . had a stroke of palsy and has remained ever since one half of his body and limbs useless" (9). Indeed, "Most of those that have been instrumental in trying to destroy me and my practice had some judgment befall them as a reward for their unjust persecutions and malicious conduct towards me." The Postmaster at Eastport, Thomson strongly suspected of stealing two fifty dollar bills from him; he fell from a precipice and was killed—naturally, that "put a stop to pursuing the subject any further" (10).

The Judge himself did not escape—in the trial for murder, indeed, he charged in favour of Thomson and escaped divine punishment; but when Thomson brought an action for slander against Dr. French for calling him a murderer, the Chief Justice, the celebrated Theophilus Parsons, was again on the bench—this time "he seemed . . . to be determined to have the case go against" Thomson and told the jury that Dr. French was completely justified in calling him a murderer. He even abused Thomson's lawyers for taking up with him, "Saying they ought to be paid in screw auger and bull dogs." And Nemesis swiftly followed—"for he soon after had a stroke and as I am informed died before the next Court met" (11). Truly he "got his."

Thomson's great discovery was Lobelia, which he called the Emetic Herb and which was the most important article in his practice—his No. 1. This he discovered when he was four years old, but it never occurred to him that it was of any value as a medicine till eighteen years afterwards when, mowing in his field with a number of men, he cut a sprig of it and gave it to a man next to him who ate it. He vomited two quarts, and never had anything do him so much good in his life. Thereafter Thomson continued to experiment with the plant for years: and finally he took out a United States patent giving him the exclusive right of using this plant for medical purposes; and he sold the right to use it for $20.

When the doctors failed in their attempts "to destroy the credit of it by . . . representing it to be a deadly poison, etc.," they changed their tactics and tried to defraud him of the discovery.

There can be no doubt of Thomson's *bonâ fide* belief in his original discovery of the medicinal properties of Lobelia. Speaking of the statement in Thacher's *Dispensatory* (13) that "it was employed by the aborigines," Thomson says: "It would be

folly for me to undertake to say but that it may have been used by the natives of this country: but one thing I am certain of that I never had any knowledge of their using it nor ever received any information concerning it from them or anyone else." Nor can any suspicion rest on his good faith.

He also says: "There is no mention of this herb by any author that I have been able to find previous to my discovering it excepting Linnaeus who had given a correct description of it under the name Lobelia inflata; but there is nothing said of its medical properties, it is, therefore, reasonable to conclude that they were not known till I discovered it" (14).

But he did not and could not know that before he was born—he was born in 1769—the celebrated Swedish botanist and traveler, Peter Kalm, a favorite pupil of Linnaeus, had found it used by the Indians of Canada as a medicine. Kalm says: "The savages of Canada have no knowledge of mercury but nevertheless they very easily cure all venereal maladies. When I came amongst them I found that it was almost impossible to learn their secret—they imagined that if their remedy once came to the knowledge of Europeans it would instantly lose its virtue. Colonel William Johnson who was very influential with them . . . at my instance . . . at length succeeded. . . .

That marvelous plant is Lobelia which grows in abundance in the wet plains and swamps.

The treatment of the Indians is of the simplest character: They boil four or six or more of the roots according to the gravity of the disease: and the patient drinks as much as he can of the decoction, following a rigid regimen, abstaining from all fermented drink and living on vegetables alone. The same infusion is employed to wash the ulcers. The treatment usually lasts fifteen days, at the end of which time the disease disappears.

With Lobelia and some other plants of the same nature, there are made in Canada astonishing cures which cannot be effected with mercury—and the difference between the two treatments is that with Lobelia the savages never run a risk of life.

There is no instance of an American, however severe his disease, meeting his death during treatment with Lobelia—there is no patient treated by this method who has not been cured" (15).

It must not be supposed that Thomson employed Lobelia for venereal disease alone—he used it for everything from ague to dropsy, from headache to piles.

In venereal diseases, he did not discriminate syphilis and gonorrhea—he preferably used his No. 3 of bayberry root bark, white pond-lily root and the inner bark of hemlock pounded and steeped in boiling water: but in early stages he used his Rheumatic Drops made of gum myrrh and brandy.

Now was he true to his principle of employing only native plants—he imported and used Cayenne pepper in large quantities and spoke most disparagingly of the native article.

Of course Thomson does not stand alone in claiming universality of healing power for one plant—the panacea is all too common in the history of medicine, regular and irregular.

The noted Joe Pye on this Continent, pinned his faith on Eupatorium purpureum, still called Joe-Pye weed: Formius of Montpellier relied upon his Syrop de capillaire made of the Adiantum capillus Veneris, our Maidenhair fern, which thence received the name Capillaire de Montpellier.

Of less notoriety, but of much greater merit and infinitely more learning than Formius or Joe Pye was Johannes Andreas Harnisch, a medical practitioner who in 1758 published at Leipsic his "Meditationes Botanico-Medicae de Planta quadam Marchiæ propria Pimpinella Nigra . . ." 4to, pp. 40 (16).

In this work, now rare but not wholly forgotten, the learned author sounds the praises of the common weed, the black or great Pimpinella.

This is a work showing much research and erudition: it is in good Latin almost wholly free from the solecisms which disfigure so much professional Latin of that and the preceding eras.

I call Harnisch, a "Pre-Thomsonian," because of the views expressed in his Praefatio.

I translate as literally as the idioms of the two languages permit, the portions of this Preface which I mean.

"Omnipotent God in his great and hidden wisdom and beneficence has not planted all and the same herbs and plants in one and the same place, but has collocated one in this, another in that—and these again are different in their shape, color, odor, taste and effect. For one is preferable to another in that it has different flowers or possesses different leaves or puts forth different fruit and seeds or glories in different root—that indeed we see if we walk the meadows, the fields, the woods and the gardens. But the most benign Creator did this for no other reason than all these should serve man. . . . I shall not touch exotic plants and those which grow in the four quarters of the world, since in this place and in that, an herb is to be found useful and preeminently suited for this or that necessity. For an example, I take Guaiacum wood, and China root (17) which two species are found in India and Sicily where the Neapolitan disease (18), now called venereal, is prevalent. Are these not the best remedies for purifying the blood in this affection and other impurities of the blood? Quinquina and Schaccarilla, two trees grown in the region of Peru where various fevers, especially the intermittent, are one might say endemic. In this kind of disease are these not splendid antifebrile medicines? And Cochlearia is found in abundance and almost wild in Belgium where scorbutus very frequently tortures and affects men. Is that not the solace of the scorbutic . . .?

Among the peculiar plants is contained Pimpinella nigra, which I deal with in the present treatise —I call it "peculiar" because it is not found everywhere, but only in particular places and it is peculiarly effective in certain particular diseases. . . . And to the thrice good and thrice great God be there for this best of plants, praise and honor and glory everlasting."

The author begins his treatise in the time honored way followed by "the best and most celebrated writers on botanical matters" by going into the name and its origin. He considers the name derived from the Latin "bis" (twice) and "pendeo" (I hang) or "Penna" (a feather), the name being due to the leaves because two leaves hang on the right side or the leaves on either side are like feathers. In this

he agrees with Hecker and Matthiolus, he disagrees with Amatus Lusitanius (19) who thought that the plant was so called because it had the odor of the citrulus (Citrullus vulgaris, or common watermelon) which the Spaniards call "pipinum" (20); for, as Harnisch says, "it has neither the odor nor the taste of the citrulus."

"Others call the plant Pampinula or Pampinella deriving the name from the noun Pampinus (21) meaning a tender and leafy little stem in a vine (*coliculus,* i. e., *cauliculus*) because the tender little stems of the Pimpinella are like the pampini of the vine.

"Others again call it Pipernella (22), which name they derive from its pungent root which has a sharp taste like pepper—and for this reason it is ineptly called German pepper, since it answers to pepper both in taste and in qualities. . . . Others call it Bibenella deriving the name from 'bibere,' to drink, because its acrid roots bring on desire for drink and drinkers if they chew this root can drink the more. In German it is called Bibenelle, Pimpenelle, Pepperwort"; but Harnisch thinks the Latin Pimpinella is far the best name.

By recent botanists including Tournefort (23), it was called Tragoselinum. Matthiolus calls it Tragoselinum or Apium hircinum (Goat parsley) either because goats are fond of it as a food or because its leaves in autumn have a hircine smell. Some call it Petroselinum hercinum, Apium petraeum, Petrapium, Saxifraga hircina, Petrasindula, Tragium alterum, in German Steineppich, Bockspeterlein, etc.

After a very complete botanical description, the author tells us that its native habitat was in the meadows within two or three miles of Frankfort.

Even before this treatise, the author, as he says, had drawn the attention of the profession to two notable cases which he had fully cured by Pimpinella, one of dropsy and one of *erysipelas suppurata et exulcerata:* and in the present work he speaks of its merits at large. And certainly they are not few.

"So far as the virtues and effect of this plant are concerned, it, by reason of its oleososulphurous and salinealkaline particles, has not only balsamic force and efficacy but also it checks putredinose corruption while it purifies the blood and separates out the impure particles from the humors and evacuates them through the ordinary *viae,* especially the urine and perspiration, by excretion and elimination.

"Moreover it soothes (*demulcet*) and as it were sweetens the blood by allaying ebullition and effervesence. So, too, this plant is to be considered as the best and safest diuretic, diaphoretic and alexipharmic (24). . . .

"Therefore we think it a splendid remedy internally in various affections as demulcent, resolvent and apophlegmatisans (25). . . ."

Three pages are taken up with an enumeration of its wondrous qualities. I select but a few of the diseases for which taken internally it is sovereign—Viscid mucus in the sinuses of the head or in the vessels of the lungs, coryza catarrhal and pectoral, cough, asthma, tooth ache, rheumatoid arthritis, ischialgia, podagria, achores infantum, scorbutus, scabies, the first stage of lues venerea, calculi, nephritis, uterine diseases, fluor alba, amenorrhea, dysmenorrhea, hysteria, colic, hemorrhoids, want of appetite, malignant and contagious diseases, putrid fevers, exanthemata, smallpox, measles, purpura, fluxus lochiorum, gonorrhea, tremors of the limbs, etc. "In the lues venerea it is to be extolled with praises in the highest degree since it cures fundamentally if it be exhibited for four or six weeks according to the state and gravity of the disease along with the use of purgatives and sudorifics."

For external application it is no less admirable. "Just as its internal use is singularly effective so also its external is clearly powerful, since by reason of the same principle . . . it soothes irritated nerves, purifies the impurities of the humors, reduces the tone to equilibrium and consolidates disunited parts. According it is administered with success in wounds for staunching the blood, in old dripping ulcers for drying them up and in cancroid, fistulous and venereal affections for healing and cleansing them.

"It also exerts great efficiency in scattering external tumors and in dissipating edematous and erysipelatous affections of the feet. Lastly its virtue is most worthy of praise in affections of the fauces, as well in simple sore throat (anginodeis) as in venereal affections."

A strangely familiar and modern touch is felt in the chapter devoted to methods of administration.

"Since nowadays it is a requisite by the practitioner of medicine that he should cure not only quickly and safely but also even pleasurably—every merit and every advantage are united in this, that crude medicines are not to be exhibited, but those that are unpleasant and nauseous to the sick are to be put in palatable form by suitable preparation and thus rendered more agreeable to the palate and more fitted for consumption."

Pimpinella when the taste is unpleasant should be given in powders, or in essences. It is regrettable to observe that the author thinks that simple spiritus frumenti is not sufficiently penetrating to extract the essence satisfactorily.

Then follows a report of sixteen cases cured by this remedy:

Achores and Tinea, the essence used, Erysipelas suppurative and ulcerated by cataplasm and essence, Arthritis vaga by powder, Ischiadicus morbus (femoro-popliteal neuralgia) by essence and powder, Hysterics with complications by essence and plaster, Catarrh, Hydrops anasarca, Testiculus venereus by essence of Pimpinella and Bals. Copaiva, Sterility by reason of Fluor alba by essence and infusion, Varioli confluent by powder, Weeping ulcer in the cheeks and chin from receding Morbilla (probably syphilitic) by essence, Erysipelas by essence, Petechial Fever by essence and infusion, Pleuriticoperipneumonic Fever by infusion, Coryza by infusion, Calculus by essence.

It must not be thought that Harnisch relied upon Pimpinella alone—any more than Thomson relied upon Lobelia alone.

We find him employing in conjunction with Pimpinella

Unguentum Rosae Nicotian.
Ol. Tart.
Syr. Cort. aurant.

Empl. saponat. camphor.
Galbanum.
Ess. Castor.
Flor. Arnic.
Mell. Rosar.
Rhubarb.
Pilulas polychrestas Hallenses.
Gummi Myrrh.
Gummi Mastich.
Folia recentia Tiliae.
Glycyrrhiz.
Tussilag.
Sambuc.
Chamom. Fol. & Rad.
Butyrum.

One can only say that he was a little more consistent than Thomson in the employment of native plants.

NOTES

1. Samuel Thomson was born February 9, 1769, in the Town of Alsted, Cheshire County, New Hampshire, and died in 1843. Almost wholly self-taught, he developed theories of his own: one is mentioned in the text, another was that minerals being of and in the earth tended to draw men to the grave while plants whose tendency was to grow upward raised them from the earth.

He has given the story of his life in a 12 mo. of 256 pp. *A Narrative of the Life and Medical Discoveries of Samuel Thomson.* . . . I use the sixth edition, Columbus, Ohio, 1832.

He and his school had much to do with the abolition of the practice of bleeding—his follower, Dr. Richard Hare Clarke of Cobourg, Ontario, was the protagonist of the opposition to bleeding in Upper Canada. Most of Thomson's followers ultimately joined the Eclectic School—Dr. Clarke among them (who was one of my preceptors, *Consule Planco*).

2. See *New Guide to Health or Botanic Family Physician* . . . by Samuel Thomson, Hamilton (Upper Canada), 1832, preface (by) L. Meeker Day, p. 4.

3. See *A Narrative of the Life and Medical Discoveries of Samuel Thomson,* etc., p. 8.

4. *Ibid.*, p. 27.

5. *Ibid.*, pp. 149, 150.

6. *Ibid.*, p. 122. The extraordinary story of Thomson's trial for murder will be found in (1809) 6 Massachusetts Report (Tyng), Commonwealth v. Samuel Thomson, pp. 134-142. Thomson gave the lad his "coffee" with a decoction of Marsh-rosemary (*Statice Limonium*) mixed with the bark of bayberry bark (*Myrica cerifera*)—the main medicine was *Lobelia inflata* (Linn.). Thomson was acquitted.

17. China Root: there were two kinds, best known, viz.: *Smilax China,* Linn., closely allied to Sarsaparilla, which was the kind grown in Sicily and elsewhere in Europe; and the kind from India (i. e., the West Indies), American or Bastard China, *Smilax pseudo-China* of the West Indies and Carolina. They have much the same qualities.

18. The French called Syphilis, *Mal de Naples,* Latinized *Morbus Neapolitanus;* the English and others, French Pox, Latinized *Morbus Gallicus*—there were literally scores of other names. In Iwan Block's work "Der Ursprung der Syphilis" (Jena, 1901) a list of names alone fills eighteen pages—pp. 297-315. See my Article "The Origin of the Word Syphillis," in the NEW YORK MEDICAL JOURNAL for May 4, 1921.

19. This Hecker was the botanist Johannes Julius Hecker (1707-1768), who published his *Einleitung in die Botanie* (Introduction to Botany) at Halle in 8 vo. in 1734.

Matthiolus (Peter Andrew Mattioli, 1501-1577), an eminent physician and medical botanist born at Sienna, educated at Venice and Padua originally for law, then for medicine, practised in Sienna, Rome and elsewhere—he died of the plague at Trent. He published his *Apologia versus Amatum Lusitanium* at Vienna in 1558, and his vegetable Materia Medica under the title *Opuscula de Simplicium Medicantorum* . . . at Vienna in 1564.

Amatus Lusitanius (John Roderigo Amato), a Portuguese physician and medical writer of Jewish origin (1511-?, not earlier than 1561) was educated at Salamanca and he taught medicine at Ferrara and Ancona. He remained attached to his religion and after narrowly escaping the Inquisition removed to Ragusa and then to Thessalonica. In his work *Enarrationes in Dioscoridem,* Venice, 8 vo., 1553; Strasburgh, 1554, and Lyons, 1557, he attacked Matthiolus, who retaliated with his "Apologia adversus Amatum," *ut suprâ*—this Apologia obtained great celebrity as a crushing reply.

20. The ordinary Spanish for watermelon is Sandia or melón de agua: but in South America, it is often called Patilla.

21. "Pampinus" is perfectly good classical Latin, being found in Pliny in this sense: Vergil, Georgics I, 448 and Horace, Odes iv, 8, 34, use it in the sense Vine-leaf or foliage of the vine.

22. Of course from the Latin *Piper,* pepper: *Pipernella* is not found in classical Latin.

23. Joseph Pitton de Tournefort (1656-1708), the celebrated botanist, born at Aix, was educated there for the Church but turned to botany. After collecting for two years he studied medicine at Montpellier but was appointed Professor of Botany at the Jardin des Plantes, Paris. His principal work is *Institutiones rei herbariae* in three volumes, Paris, 1700: he also published *Histoire des Plantes qui naissent aux Environs de Paris, avec leur usage dans la Médicine,* Paris, 1698, 12 mo.

24. A term formerly much used to indicate a medicine for expelling foul or corrupt humors from the blood or to prevent evil effects from poison taken inwardly; it is still occasionally used, e. g., in the *New English Dictionary.*

25. Apophlegimatisans—applied to medicine for removing phlegm from the head—either *per nares,* i. e., errhine, or *per os,* i. e. sialagogue.

OSGOODE HALL.

Contributors to the Science of Medicine

SIR ASTLEY COOPER

Sir Astley Cooper was the first celebrated surgeon in England who learned his anatomy and much of the medical science he possessed from the great John Hunter. While he was not the intellectual successor of John Hunter, Hunter's influence was beneficial and he had the wit to perceive, as many of his medical and surgical brethren of the day had not that wit, that Hunter was not "an imaginative speculator, and anyone who believed in him a blockhead and a black sheep in the profession." Cooper was a born surgeon and a practical man with a keen shrewd brain and one who advanced the art of surgery immensely.

Astley Paston Cooper was a grandson of a surgeon in Norwich, England, and his father was a clergyman in Norfolk, of which Norwich is the county town. His boyhood was a stirring one and marked by a succession of hairbreadth escapes and exploits demanding coolness and audacity. He had no taste for books and like John Hunter he had a free youth, which was neither improved nor spoiled by systematic training. In 1784 he was articled to his uncle, a well known surgeon, in London, and transferred to Mr. Cline, one of the leading surgeons of the day. Under Cline young Cooper imbibed the spirit of Hunter's teaching from one of his most enthusiastic pupils, for Cline's judgment of Hunter was, that there seemed no comparison between his great mind and all who preceded him. Cooper spent one winter session in Edinburgh, having already made considerable progress in anatomy and surgery. After returning from Edinburgh he attended the lectures of John Hunter and those of other celebrated lecturers. In 1789, being only twenty-one, he was appointed demonstrator at St. Thomas's Hospital. Two years later Mr. Cline obtained for him the joint lectureship with himself in anatomy and surgery at St. Thomas's Hospital.

In 1791 he married a rich girl and in June, 1792, the young surgeon and his bride visited Paris and were there during the three terrible first months of the French Revolution. Cooper spent much time in studying French methods of surgery, and in attending the debates of the National Assembly. His safety was insured by wearing a democratic badge and by friendship with leading revolutionists in England. Owing to his wife's money he was placed beyond pecuniary anxiety and was able to devote himself mainly to study and teaching. He went to the hospital before breakfast to dissect for lectures, and he also demonstrated to students before the lecture hour. He lectured from two until half past three, and on three evenings in the week lectured on surgery. He was the first in the borough hospitals, St. Thomas's and Guy's, to separate surgery in lectures from anatomy and physiology. At about this time he was selected as lecturer on anatomy at the College of Surgeons.

In 1800 Astley Cooper was appointed surgeon to Guy's, and it was at this time that Mr. Travers, who became his articled pupil,, said of him that he was the handsomest, most intelligent looking and finely formed man he ever saw. According to the custom of the time he wore his hair powdered, with a queue. Dr. William Roots says: "From the period of his appointment to Guy's until the moment of his latest breath, he was everything and all to the suffering and afflicted. His name was a host, but his presence brought confidence and comfort; and I have often observed that on an operating day, should anything occur of an untoward character in the theatre, the moment Sir Astley Cooper entered, and the instrument was in his hands, every difficulty was overcome, and safety generally insured."

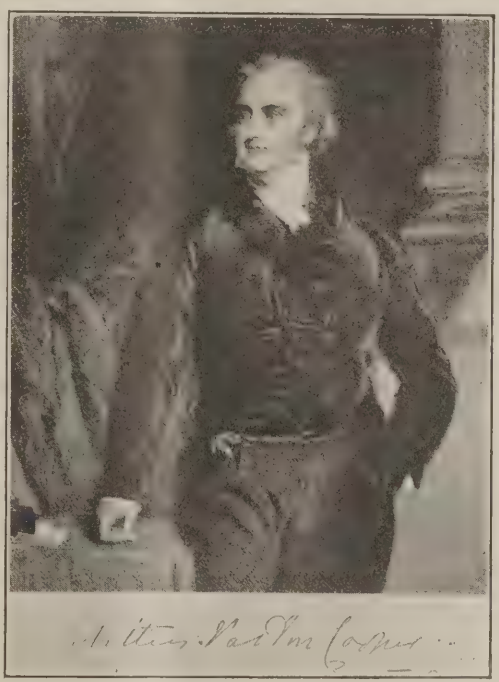
To Sir Astley Cooper, as to most men who rise to eminence, remunerative practice came but slowly. "My receipt," says he, "for the first year was £5 5s.; the second £26; the third £54; the fourth £96; the fifth £100; the sixth £200; the seventh £400; the eighth, £610; the ninth, the year in which he was appointed surgeon to the hospital, £1,110. He never, however, forgot the scientific side of the profession, even though it cost him money. Thus we read the following entries in regard to obtaining the body of a man on whom he had operated twenty-four years before: "Coach for two there and back, £3 12s.; guide and coachman, six shillings; expenses for two days, £1 14s. 6d.; carriage of subject and porter, twelve shillings and sixpence; subject, £7 7s.; total, £13 12s. From 1806 to 1815 Sir Astley Cooper reaped a rich harvest. In one year his income amounted to £21,000, and for several years it was £15,000 a year. One merchant prince paid him £600 a year.

The story of another who tossed him a check for a thousand guineas in his nightcap after a successful operation for stone is well known. In those years he rose at six, dissected privately until eight, and from half past eight saw large numbers of patients gratuitously. At breakfast he ate only two well buttered hot rolls, drank tea, cool, at a draught, read his paper for a few minutes, and then betook himself to his consulting room. Patients crowded his rooms and besieged Charles, his serving man, using manifold devices to get the earliest interview possible. Sometimes the people in the hall and anteroom were so importunate that he was driven to escape through his stables and into a passage by Bishopsgate Church. At Guy's he was awaited by a crowd of pupils on the steps and at once went into the wards. His few pertinent questions and quick diagnosis were of themselves remarkable, no less than the judicious, calm manner in which he enforced the necessity for operations when required.

At two o'clock the students would suddenly leave the wards, run across the street to old St. Thomas's Hospital, and seat themselves in the anatomical theatre. After the lecture, which was often so crowded that men stood in the gangways and passages near to gain such portions of his lecture

as they might fortunately pick up, he went round to the dissecting room, and afterwards left the hospital to visit patients or to operate privately, returning home at half past six or seven. Every spare minute in his carriage was occupied in dictating to his assistants notes or remarks on cases or other subjects on which he was engaged. At dinner he ate rapidly and not very elegantly, after dinner he slept for ten minutes or so, and then started to his surgical lecture, if it were lecture night. In the evening he was usually again on a round of visits up to midnight.

Dr. Pettigrew, in his *Medical Portrait Gallery,* thus describes the overpowering influence Sir Astley Cooper had upon his pupils: "I can never forget the enthusiasm with which he entered upon the performance of any duty calculated to abridge human suffering. This enthusiasm, by the generosity of his character, his familiar manner, and the excellence of his temper, he imparted to all around him, and the extent of the obligations of the present and of after ages to Sir Astley Cooper in thus forming able and spirited surgeons can never be accurately estimated. He was the idol of the Borough School—Guy's and St. Thomas's are on the south side of the Thames in the district popularly known as the Borough. The pupils followed him in troops; and like to Linnaeus, who has been described as proceeding upon his botanical excursions accompanied by hundreds of students, so may Sir Astley be depicted traversing the wards of the hospital with an equal number of pupils listening with almost breathless anxiety to catch the observations which fell from his lips. But on operating days this feeling was wound up to the highest pitch. The sight was altogether deeply interesting; the large theatre of Guy's crowded to the ceiling, the profound silence obtained upon his entry, that person so manly and truly imposing and the awful feeling connected with the occasion can never be forgotten by any of his pupils. The elegance of his operation, without the slightest affectation, all ease, all kindness to the patients, and equally solicitous that nothing should be hidden from the observation of the pupils, rapid in execution, masterly in manner, no hurry, no disorder, the most trifling minutiæ attended to, the dressings generally applied by his own hand, the light and elegant way in which Sir Astley Cooper employed his instruments always astonished me, and I could not refrain from making some remarks upon it to my late master, Mr. Chandler, one of the surgeons of St. Thomas's hospital. I observed to him that Sir Astley's operations appeared like the graceful efforts of an artist in making a drawing. Mr. Chandler replied: "Sir, it is of no consequence what instrument Sir Astley uses; they are all alike to him, and I verily believe he could operate as easily with an oyster knife as with the best piece of cutlery in Laundy's shop."



For two seasons he lectured at the College of Surgeons on comparative anatomy. Not being deeply read in the subject he resolved to see what industry would do and restricted himself to three or four hours' sleep that he might gain additional time for the dissection of animals. He also employed several assistants to dissect for him, and the result was that his specimens came by coachloads to each lecture. At this time he signalized his skill by his celebrated operation of tying the aorta for aneurysm in a case in which life was in the direst peril. The ease with which he prepared for the operation and the masterly skill and success with which he completed it, without the aid of anesthetics be it remembered, excited admiration throughout the profession. Some years later, in 1824, he amputated at the hip joint, the first time it is believed the operation had been performed. The whole operation with the dressing of the wound took half an hour. Sir Astley's fame was international, so that distinguished foreign surgeons never failed to visit him at Guy's Hospital. In January, 1925, he resigned his surgeoncy at Guy's and lecturership at St. Thomas's, owing to the impairment of his health. The death of his wife in 1827 so greatly affected him that he determined to retire from practice altogether. Before the end of the year, however, he found the boredom of retirement unsupportable and returned to town and was soon in full practice again. He wrote several books, among these *Diseases of the Breast, Diseases of the Testes,* and *The Anatomy of the Thymus Gland.* He was twice president of the College of Surgeons and in 1833 received the decoration of the Legion of Honor from the King of the French. He died on February 13, 1841, and is buried beneath the chapel of Guy's Hospital.

There is little doubt that Sir Astley Cooper was one of the great surgeons of the world. He operated in the days when rapidity was almost a *sine qua non* of successful surgery. As there were no anesthetics there was no time to consider the next step as now, and because antisepsis or asepsis was unknown promptitude was additionally essential for successful surgery.

According to an estimate made by himself he was a better anatomist than operator. Rapid and correct diagnosis was his forte and the same faculty made his prognosis good. In his opinion his success depended up his zeal and industry. Contemporary medical history records, however, that as an operator he had few equals and with the exception of Robert Liston, perhaps no superior.

Editorial Articles

LENGTHENING OF LIFE OF GREAT MEN

The average length of life is considerably greater than formerly. In fact, it has been stated recently by a statistician, although it has been whispered that some statisticians are liable to err, that a child born today has a reasonable expectation of twelve years more life than his grandfather. However, it is certain that life has lengthened and it seems is still becoming longer. Moreover, the saving of infant life in civilized countries and especially in English speaking countries is proceeding apace almost *pari passu* with the decrease of the birth rate. An article which came out in the March issue of the *Nineteenth Century and After* brings forward some startling figures with regard to the length of life. The author, Mr. A. Wyatt Tilby, points out that if any consecutive death announcements in the daily journals, omitting the rare announcements of deaths under the age of twenty-one, are scanned, it will be found that the average length of life is 70.3 years. But the figure is deceptive, because the announcements refer principally to the more prosperous classes of the community, and because the obituaries of women almost invariably omit any mention of age. However, what Mr. Tilby set out to discover is whether exceptionally distinguished men in all branches of activity have an overaverage or an underaverage length of life.

From the report it appears that rush is rather conducive to long life than not, and that the doer stands a better chance of long life than the thinker or dreamer. Mr. Tilby holds that the comparatively long life of the men of action as well as their eminence are largely due to the fact that they are a naturally selected class, that is, a man is not likely to rank high as a statesman or a soldier unless he is stronger mentally and physically than the average man. The contemplative class, on the other hand, includes men of inferior physique. Indeed one reason for their contemplative habits may be the state of their health, which precludes any great expenditure of physical or nervous energy. At the same time a man can cogitate, compose, or paint, with half a lung out of action, or a disordered gastrointestinal tract, and many who do this, in the nature of things, die young. But even contemplative distinction is an advantage, for the average of those who have reached this distinction is 64.3, as against the sixty-two of the ordinary individual. Actors have an average life of nearly seventy years. A busy full life tends to longer life than a peaceful thoughtful one, although of course, as pointed out previously, men of action, as a rule, are such because they are bountifully endowed with vitality, not necessarily of especially strong physique, but with abundant nervous energy. It is frequently the small wiry individual, instinct with the vital spark, who lives the longest and does the best work.

The "will to live" and an object in life must be taken into account. The person who has no strong aim in life or no one or nothing in particular to live for is lacking in the will to live. The mind has a great influence over the body, and when the strong desire to live has become dull, life is not likely to be long. Moreover, it is a fact that life has lengthened and that great men, as a rule, live the longest.

TABACOSIS

Tobacco smoke, besides nicotine, the proportion of which varies with different kinds of tobacco, also contains carbon oxide, carbonic acid, ammonium cyanide, pyridine, and various other basic substances of highly toxic nature, but in minute quantity. The absorption of these substances, in minimum amount, but continued for a long time, produces conditions which may be overlooked although they are dangerous for the person's future. These occur in the functions of the digestive and nervous systems. There is irritation of the buccal, pharyngeal, and laryngeal mucosæ with the frequent production of a slight cough. The appetite decreases, while digestion becomes difficult when immoderate smoking is indulged, and diarrhea may also ensue.

There are two characteristic nervous symptoms of nicotinism—namely, palpitation and weakened memory, especially for proper names. At a more advanced phase, chronic tabacosis produces nausea, vertigo, and dizziness, after which a decrease of the acuity of vision is noted. The impregnation of the neurons by nicotine and by the other products of incomplete combustion of tobacco, differs from the saturation of the organism by alcohol, in that it is not tenacious, while alcoholic impregnation is extremely persistent. In reality, it is sufficient to cease the use of tobacco for all the untoward symptoms rapidly to subside.

It sometimes happens that the disturbances of nicotinism suddenly develop in a smoker who, nevertheless, has not increased his daily ration of tobacco. Searching for the cause of this sudden and surprising susceptibility, it will be found that it can be attributed to the fact that the patient returning from a sojourn in the country, where he smoked in the open, to his city abode, where he smokes in his con-

fined rooms, inhales for hours an atmosphere saturated with tobacco fumes which, in reality, means that he has smoked the same cigars or pipe several times over. The same applies to persons who have stopped smoking on medical advice, and continue, nevertheless, to present disturbances of tabacosis, this persistence being readily explained by the fact that they still frequent the homes of people who smoke, and pass considerable time in rooms saturated with tobacco smoke.

For a similar reason an attenuated form of nicotinism may be met with in women and children who do not smoke. It is to be recalled that subjects with a nervous and especially a rheumatic temperament badly tolerate tobacco, and that women and children offer in respect to this a great susceptibility. Likewise the fact should not be overlooked—in order to explain sudden outbursts of accidents due tobacco or caffein, that tobacco and coffee are, in a notable degree, antidotes, and that their absorption is usually simultaneous. Now, in the case of a heavy smoker and consumer of coffee, it may for some reason happen that he decreases his daily intake of coffee or even ceases to take it, the result being that the accidents of nicotinism immediately develop.

In the same circumstances, the sudden suppression of the use of tobacco will cause the appearance of the minor disturbances dependent upon the consumption of coffee. Hence it is necessary, when a decrease or complete suppression of either one of these psychic stimulants is required, to advise the decrease of each at the same time.

THE PYELONEPHRITIDES

The latest researches on the pyelonephritides show the action of the numerous intestinal bacteria in these renal infections. For example, Heitz-Boyer, by demonstrating the existence of an enterorenal syndrome in these cases, has shown that the infection, starting from the intestine, reaches the kidney and renal pelvis by the circulation, but occasionally the infection follows a direct route at those points where the digestive tract is in direct contact with the kidney. From this it follows that the bacteria most often in play in these infectious processes are those normally living in the intestine and whose number has been increased or their virulence increased by some enteric affection, such as enterocolitis, appendicitis, or even typhoid fever. In the pus of pyelonephritis will be found the bacterium coli or similar germs, such as the enterococcus, and in certain special circumstances the bacillus of typhoid. Le Fur has pointed out that the staphylococcus may play an important part in renal infection and is often as unsuspected etiological factor.

These ideas have as a corollary some changes in the therapeutics which have been resorted to until recently. Among other methods, vaccinotherapy has become an important resource. According to the given case, vaccines containing the staphylococcus, the enterococcus, and almost always the colon bacillus are to be employed. The most recent clinical data published show the really remarkable results obtained by vaccines in pyelonephritis, these having singularly facilitated the treatment. This does not imply that the older treatments are to be discarded. Vaccines act rather more on the general infection than on the local renal manifestations. Hence it follows that disinfection of the urinary tract with formin should still be employed. Balsamic medication, with disinfectants, still remains the basis of treatment of pyelonephritis, the only inconvenience arising from it being the occasional congestive action on the urinary mucosa, but this untoward effect can be avoided if the substance prescribed be free from impurities, as irritant action will thus be eliminated.

The conclusion is that at present the proper treatment of these renal infections is still intestinal and urinary disinfection combined with the use of vaccinotherapy.

BODYSNATCHERS

When we were younger, there was talk of bodysnatchers and graverobbers and a general impression in our village (at least among the children) that they were more than a myth. Just who they were and why seemed a mystery about which there was little conjecture, though dissecting rooms were sometimes spoken of in this connection. There is mention of bodysnatching in Dickens's *Tale of Two Cities,* but the object, as we recall the story, was robbery. We have doubted that the gruesome business was ever practised except for securing jewelry, but we find we were mistaken.

Dr. Cobb tells, in the *Boston Medical and Surgical Journal,* of how his grandfather, Archelaus G. Smith, was so keenly interested in his cases that he never let slip an opportunity of securing a postmortem examination. "One of his patients, 'in spite of all he could do, wasted away and finally died.' He was determined to learn the cause of death, but an autopsy was refused, so after the funeral he went at night to the cemetery and brought the body back to his barn, where he made the examination and then prepared and mounted the skeleton, which was thereafter kept in a closet off his study. Years later this skeleton was accidentally recognized by a suspicious relative who based the identification on the fillings of the teeth. Dr. Smith was brought to trial. When it was proved that the grave had in truth been robbed, he was so fearful of conviction

that he had horses stationed every five miles in order to make an escape over the Canadian border. But the lawyers succeeded in discrediting the witness who identified the skeleton—he became confused and said the telltale fillings were on the right instead of the left side of the jaws. Thus Dr. Smith was acquitted and did not have to make use of his plans of escape."

To the average and, indeed, to the great majority of medical students, such eagerness for autopsies must seem abnormal, and certainly is extraordinary, but there have been such enthusiastic seekers after truth. We do not like to question the accuracy of the story by suggesting that dental fillings must have been rare a hundred years ago, but, after all, their rarity may argue for the truthfulness of the tale, inasmuch as they would have served better by way of identification than in the present day when they are so common. It is a good story and we like to believe there were such diggers after knowledge among the bodysnatchers. They set us a shining, if unlawful, example, but there is little danger that any of us would be so daring as to follow it. Fortunately we live in a day when anatomical and pathological material is obtained more readily and without breaking the laws.

BESREDKA'S VIEWS ON IMMUNITY

It seems that Dr. Prosch and Professor Dahmer of Berlin have isolated the virus of foot and mouth disease, at least, the *Lancet* of May 10th in an editorial accepts their claims as genuine, subject to confirmation by the Berlin Department of Health and the Koch Institute. It is a very minute organism, ultramicroscopic. Professer Dahmer has succeeded in preparing a culture wherein the bacilli may be propagated so that it appears that not only has the virus been isolated, but an inexpensive method of propagating the germs and thus making a vaccine has been devised. This is good news, as foot and mouth disease has been the cause in recent years of great losses to farmers and the community at large. In California the disease has been particularly rife, and correspondingly costly. If, as the Berlin investigators state, a means for detecting filterable viruses has been thought out, the minute bacilli of many infectious diseases which attack human beings will be discovered, and probably in most instances a method of producing immunity established.

In this connection Besredka's views on immunity are especially interesting, as he made certain experimental observations on foot and mouth disease. Besredka's contention is that immunity in certain diseases is developed, not as is the usual belief in the blood stream, but in the cells of the particular tissue attacked by the causal organism. In support of this contention, he reports more favorable results when vaccines are administered directly to the tissues which are predilection sites for the attacking organisms, that is, the intestine in typhoid fever and the skin of guineapigs in anthrax, than when vaccination is made subcutaneously in the usual way. It is common knowledge that among the filterable viruses there exist certain groups which have a well defined affinity or predilection for certain tissues. In this connection a neurotrope group, attacking nerve tissues, and an epitheliotrope group, attacking the epithelial covering of the skin and mucous membranes, may be recognized. In the former group may be included such viruses as those of rabies and encephalitis of rabbits; while to the latter group belong smallpox, cowpox, foot and mouth disease, and stomatitis of sheep. Terni suggested that an immunity produced by a natural attack of foot and mouth disease could be separated into tissue immunity and blood immunity. These suggestions have been fully confirmed.

The conclusions from these confirmatory investigations appear to justify the conclusion that a separate tissue immunity is present in the epithelial lesions immediately after the generalized eruption has subsided, about forty-eight hours after inoculation, whereas the blood immunity only develops some five days later. With regard to the immunity from a natural attack, it has been found that the tissue immunity is considerably shorter than that brought about by blood immunity. It would seem then that tissue immunity is a factor of no great value in protecting against foot and mouth disease, and that it is upon blood immunity that reliance must be chiefly placed for protection against this disease. At any rate, blood immunity is more lasting.

Consequently it may be confidently assumed that Besredka's claim that immunity is exclusively or chiefly a property of the cells of the attacked tissues does not stand in the instance of food and mouth disease. Whether this assumption holds for other filtrable viruses of human disease similar to those of foot and mouth disease remains to be proved, although the argument in favor of the validity of this assumption appears to be strong. The question of whether a blood immunity is superior in all cases to a tissue immunity is a most important one, and worthy of close consideration. It may be emphasized that comparative medicine may greatly aid in solving many of the obscure problems in the causation of disease and may point the way to their prevention and perhaps extirpation. The cooperation in research work of members of the medical and veterinary professions is a good augury for the future of research.

VENEREAL DISEASE IN GREAT BRITAIN

During and since the war, venereal disease has been quite prevalent in Great Britain; so much so, indeed, that it aroused a great deal of apprehension and means were sought to combat it. The National Council for Combatting Venereal Diseases was formed, and this body devised methods for treating the diseases in their early stages. However, it was recognized by many British authorities that if the disease were to be stamped out drastic preventive measures must be introduced. For this purpose the Society for the Prevention of Venereal Diseases was established. Sir Arbuthnot Lane and Dr. J. H. Sequiera were among the original members, but the success of the society was largely due to the efforts of the secretary, Dr. H. Wansey Bayly.

This society recognized that the only hope of abolishing these diseases was by radical methods of prevention. The main one of these was that druggists should be permitted to sell disinfectants, to be used immediately after intercourse. Of course, such a proposal raised a storm of protest, chiefly on moral grounds, but the society stood firmly by their expressed views. However, the National Council for Combatting Venereal Diseases opposed the suggestions of the society on various grounds, and the two bodies, each of them representing the highest medical opinions of the country, have been at loggerheads on the question. This attitude has been greatly to the disadvantage of the community at large, and it is satisfactory to state that an agreement on the recommendation in dispute has been arrived at between these bodies, which only requires ratification by the Ministry of Health and the Government to become law.

A joint conference was held between the National Council for Combating Venereal Disease and the Society for the Prevention of Venereal Disease in London, on October 30th last, at which the following resolutions were adopted. 1. That the ultimate fusion of the two societies is desirable. 2. Subject to the approval of their respective executives, this conference resolves itself into a deputation to the Minister of Health to urge "that the law should be altered so as to permit properly qualified druggists to sell *ad hoc* disinfectants provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority. 3. That this conference recommends that the respective executives of the two societies should each appoint not more than five members to form a liaison committee between the two societies and to explore the possibilities of fusion.

It seems now that the two societies are in agreement with regard to resolution 2, which was the chief stumbling block to the union, that there is nothing to prevent their amalgamation. This will be a long step forward, as it stands to reason that so long as there is division among the best authorities, and the medical profession generally, as to the most effective ways of treating and preventing venereal diseases, the public will have little confidence in the medical profession, and everyone will suffer. The only manner in which venereal disease can be abolished or abated is for a united medical profession to take counsel with respect to the most effective methods of preventing and treating these infections and especially of preventing them. An infected person, and a woman in particular, is a menace to the community, and therefore prevention is far better than cure as regards syphilis and gonorrhea. The method recommended by the British Societies may not be the best possible, but it is worthy of trial and in the meantime the brains of those skilled in the matter will be learning by experience and thinking out new ideas to cope successfully with an unparalleled situation.

EFFECT OF CARBONATION ON BACTERIA

An instructive experimental study of the effect of carbonation on bacteria in beverages has recently been made through the Mellon Institute of Industrial Research of the University of Pittsburgh, the results of which are published in a recent number of the *American Journal of Public Health.* These showed clearly the marked inhibitive and germicidal properties of carbon dioxide, and the higher the pressure of this, the more rapid and valuable the effect. When not carbonated, the average bottled beverage is an especially suitable medium for accelerated bacterial propagation, as a result of which it becomes highly contaminated. On the other hand, carbonation prevents multiplication of bacteria and causes reduction in count. The result is that a beverage carbonated and bottled under sanitary conditions, and with sufficient pressure, remains sanitary and improves with storage. If this beverage should in some way become contaminated, there would be no multiplication of bacteria, but a gradual sterilization effected, even under adverse conditions of temperature. The findings indicated that, since the effect on bacteria is proportional to the amount of carbonation, it would be advantageous to the bottler, as well as a safeguard to the public, to adopt higher carbonating pressure than is customary.

Pasteurization as a substitute for carbonation is criticized as changing the flavor and appearance of the beverage. The writers advocate that the bottler should not rely wholly upon the effect of carbonation to insure a sanitary condition of his products, since carbonation with insufficient gas may result in a dangerous beverage being marketed. Even when a high degree of carbonation is used, an initially dangerous concentration may be still too high when the beverage is consumed, if this is done immediately after bottling.

THE FRIENDS OF MEDICAL PROGRESS

The Friends of Medical Progress is a recently organized society whose aim is the promoting of medical investigation. It is a national lay organization which will undertake to inform the public of the truth about the value of scientific medicine to humanity and to animals, and which will oppose legislation dangerous to public health and welfare. The headquarters of the society are at 28 Newberry Street, Boston.

An editorial in a recent number of the *Bulletin* of the New York City Health Department comments on the value of such a body as the Friends of Medical Progress as follows: "Within the last fifty years many societies have been organized to prevent the advancement of medical science by experimental methods, to break down the bulwarks of preventive medicine, and to substitute for the scientific treatment of disease various forms of pseudoscience and quackery. We are in a position to know that these organizations have reached the danger point. It must be fully understood that if this antimedical program should succeed, the hands of the doctors would be tied and no further progress in experimental medicine could be expected. No reliable insulin would be available for diabetes, no antitoxin would be possible for diphtheria or lockjaw, no vaccine could be procured to protect the country against smallpox, and it would be utterly impossible to test such essential drugs as ergot, pituitrin and digitalis. With a view to resisting the efforts of these societies, the 'Friends' have been organized and incorporated."

Obituary.

ERNEST LAPLACE, M.D.

Philadelphia

Dr. Ernest Laplace, well known in this country and abroad, not only for his surgical work but for his activities in connection with Franco-American relations, died at his home in Philadelphia on May 15th from heart disease. He had been ill for a week, but had rallied and seemed to improve, so that death came quite unexpectedly.

Ernest Laplace was born at New Orleans, July 9, 1861, the son of Basil Laplace, a well known chemist, and Eugénie Sauvage Laplace. He was educated at Georgetown University, and received his medical degree from the University of Louisiana. Later he went abroad for further medical work, pursuing courses at the Faculté de Médicine at Paris, from which he received a second degree in medicine, and studying under many famous men, among them Pasteur, Lister, Koch, Virchow, and Billroth. He was the possessor of one of those rare vials of veal broth sealed seventy-six years ago by Pasteur to prove that there can be no decomposition without bacterial growth, and no bacterial growth without contamination.

In 1888 Dr. Laplace was appointed demonstrator of pathology and bacteriology at Tulane University, and visiting surgeon to the Charity Hospital of New Orleans. In 1889, when he was only twenty-eight years of age, he was called to the chair of pathology in the Medicochirurgical College of Philadelphia, and in 1892 was elected professor of surgery, pathology, and clinical surgery in the same institution. He held the positions of surgeon to the Philadelphia Hospital, St. Agnes's Hospital, and the Samaritan Hospital. In 1894 he was appointed by Archbishop Ryan to succeed the late Dr. William V. Keating as medical director of St. Joseph's. He was also surgeon to the Medicochirurgical Hospital and to the American Hospital for Diseases of the Stomach. Later he was appointed a member of the Pennsylvania State Quarantine Board, and was commissioned to visit Berlin to study the Koch treatment for tuberculosis. In 1916 Dr. Laplace was appointed professor of the principles of surgery at the Medicochirurgical College, and this chair was later merged with that of surgery, pathology, and clinical surgery, which he had occupied for nearly twenty-five years.

In 1923 the Academy of Paris made Dr. Laplace one of its officers. He was also a member of the Anatomical Society of Paris, the National Association of Military Surgeons, the American Medical Association, the Philadelphia Academy of Natural Sciences, and several other local medical societies. In 1921 he was made a member of the Pennsylvania State Council of Education, and held the presidency of the Medical Club of Philadelphia in 1922. During the World War, Dr. Laplace served with the rank of major at one of the military hospitals in the South. After the War, he made several trips abroad as an unofficial liaison officer in the interest of preserving friendly relations between this country and France. The latter country had made him in 1906 a Chevalier of the Legion of Honor, in 1921 he was advanced to the rank of officer, and in 1923 to that of a commander.

Dr. Laplace was best known to the medical profession as a brain surgeon and authority on diseases of the stomach and intestines. He was the inventor of the forceps used in operations for intestinal anastomosis. His death at the comparatively early age of sixty-three comes as a great loss to the profession.

HARRY RODMAN, M.D.

New York

Dr. Harry Rodman died in New York on April 29th after a brief illness at the age of fifty-one. He is survived by his widow and a son and daughter. Dr. Rodman was graduated in 1895 from the College of Physicians and Surgeons, after which he went to Mount Sinai Hospital where he received his clinical training. His specialties were diseases of the joints, and of the ear, nose and throat, and in the practice of these lines of medicine he achieved a marked success and was well known throughout New York City and State.

Dr. Rodman was a member of the American Medical Association and a fellow of the American College of Surgeons. At the time of his death he was vice-president of the Clinical Society of the Hospital for Joint Diseases, surgeon and chief clinician of the Bronx Eye and Ear Infirmary, and chief clinician of the Joint Dispensary of the Hospital for Joint Diseases. His death is a distinct loss to the medical profession of New York.

News Items

Police Department Appointment.—Dr. Seymour Oppenheimer has been appointed chief of the honorary board of consultant surgeons of the police department of New York.

Chlorine Clinic.—The Department of Health has opened a clinic for the study and treatment of certain respiratory diseases by chlorine gas, as part of the public health station at 345 East 116th Street.

Staff Assistants at St. Mark's Hospital.—The Department of Urology at St. Mark's Hospital announces that there are two vacancies in its staff. Application should be made to Dr. Victor C. Pedersen.

Field Representative for Cancer Association.—The American Society for the Control of Cancer has appointed as its field representative, Dr. William F. Wild, who had been the executive secretary of the Minnesota Public Health Association.

Sterilization of Insane.—The state board of eugenics has taken up the matter of operations for the sterilization of the insane conducted at the State Insane Asylum, Montana, some of which were performed without the consent of the board, as provided for in the law.

Health Education Conference.—The Health Education Division of the American Child Health Association has called a working conference on health education, which at the invitation of the Massachusetts Institute of Technology, will be held in Cambridge June 23d to 29th.

Masonic Medical Charity.—The income from the Manhattan opera house, owned by the Consistory of the Scottish Rite Thirty-second Degree Masons of New York, is to be devoted to the establishment and maintenance of a hospital for chronic diseases, including a laboratory bureau for general research.

Doctor de Schweinitz Honored.—Dr. George E. de Schweinitz of Philadelphia was presented with a bronze plaquette at the conclusion of his address to the Société Française d'Ophtalmologie, of Paris. A few days later he addressed the Société d'Ophtalmologie Belgique, and was unanimously elected a member.

Army Medical Services.—Graduation exercises were held on June 6th in the formal garden of the Army Medical Centre, Washington, D. C., for the Army Medical School, the Army School of Nursing, the Army Veterinary School, and the Army Dental School. Diplomas were presented by the Secretary of War.

Brooklyn Society of Internal Medicine.—The following officers have been elected by the Brooklyn Society of Internal Medicine: president, Dr. Bernhart A. Fedde; secretary, Dr. J. Francis Ward; treasurer, Dr. Charles E. Hamilton; and councilors, Dr. L. Buist, Dr. Ed. E. Cornvall, Dr. Robert E. Coughlin, and Dr. Harry Wolfer.

Maryland Health Officers Meet.—The annual conference of Maryland health officers was held in Baltimore, June 6th. A feature of the meeting was an address by Dr. George E. Vincent, president of the Rockefeller Foundation. A discussion was held on the problems of the isolation of pneumonia cases, and etiology and methods of preventing scarlet fever.

New Medical Journal.—The *Franco-British Medical Journal* is soon to publish its first number, through John Bale, Sons, and Danielsson, Limited, of London. This Journal will contain an equal number of English and French articles, the latter in English translation. The object of the Journal is to advance the medical entente cordiale between the two countries.

American Gynecological Society.—The following officers were elected at the annual meeting of the American Gynecological Society: president, Dr. Howard C. Taylor, of New York; vice-presidents, Dr. Franklin S. Newell, of Boston, and Dr. Frederick J. Taussig, of St. Louis; secretary, Dr. Arthur G. Curtis, of Chicago; and treasurer, Dr. Charles C. Norris of Philadelphia.

Medical Women's International Association.—An interesting program has been planned for the meetings of the Medical Women's International Association, which is to be held just before the meetings of the British Medical Association in July. Among the social features are teas at Lambeth Palace, Hampton Court, and at the House of Commons as guests of the Prime Minister. The British Medical Women's Federation will hold a reception.

Cancer Society Meeting.—The first annual meeting of the American Association for the Study and Cure of Cancer was held in Chicago on June 11th.

New Clinic.—The Department of Stomatology of the Midtown Hospital, New York, has recently opened clinics for pyorrhea, extraction of teeth, and oral surgery.

Epidemic of Mumps.—During the month of May, 547 cases of mumps were reported by the Department of Public Health of Pittsburgh, this being a contrast from 68 in the month of May, 1923.

Doctor Lorenz Celebrates Birthday.—A feature of the celebration of the seventieth birthday of Dr. Adolf Lorenz, of Vienna, was the unveiling of a life size plaque at the General Hospital, to commemorate his achievements.

Course in Tuberculosis.—A special postgraduate course will be given August 11th to 23d, by the Fellowship of Medicine and Postgraduate Medical Association of England, at the Hospital for Consumption and Diseases of the Chest.

National Health Council Appointment.—Dr. A. J. Lanza has been appointed executive officer of the National Health Council. Doctor Lanza, formerly of the Public Health Service, has been in Australia assisting in the organization of the Commonwealth Health Department.

Course in Gastroenterology.—A four weeks' graduate course in gastroenterology will be given by Columbia University, at the Vanderbilt Clinic, from July 2d to 30th, and repeated from August 1st to 27th. John L. Kantor, Ph.D., M.D., Associate in Medicine of Columbia University, will be the instructor.

New York Health Officers' Convention.—The annual conference of health officers and public health nurses of the State of New York will be held at Saratoga Springs, June 24th to 26th. Addresses will be made by Dr. Simon Flexner, and by Surgeon General Cumming of the Public Health Service.

Appeal for Austrian Physician.—Through Dr. Henry M. Fischer, of Philadelphia, word has been received that Dr. H. C. Kiehaupt, of Vienna, now over seventy, has been unable to teach for the last four or five years, and is in great want. An endeavor is being made to bring the matter to the notice of the pupils of Herr Kiehaupt, in the hope that his distress may be relieved. Contributions may be sent to Francis Fisher Kane, 718 Real Estate Trust Building, Philadelphia, or direct to H. C. Kiehaupt, Tigergasse 38/16, Wien VIII, Austria.

Intern Training.—The Public Health Committee of the New York Academy of Medicine has passed a resolution to the effect that medical interns in general hospitals should have a brief internship in a hospital for contagious diseases. The city Department of Health has made plans to affiliate hospital training schools of the city, and the Committee resolution continues, . . . "and views with favor the opportunities afforded at Willard Parker Hospital to give opportunities to nurses for special training in the care of communicable disease."

Tuberculosis Research.—The Colorado Foundation for Research in Tuberculosis is being developed by philanthropic citizens of Colorado Springs, to carry on the work done the last eighteen years by Dr. Gerald B. Webb and his associates, of that city. Colorado College has offered temporary laboratory facilities. The trustees consist of fifteen local and national philanthropists, and there is an advisory council including, among others, Dr. Victor C. Vaughan, of Washington, Dr. James A. Miller, of New York, Dr. Lawrason Brown, of Saranac Lake, Dr. Livingston Farrand, of Ithaca, Dr. Allen K. Krause, of Baltimore, and Doctor Webb, who also is to be one of the medical directors.

Neuropathic Hospital.—A great departure in the treatment of mental defects has been made in the planning of the new Neuropathic Hospital, to be built at Bronx Boulevard and East 236th Street, New York. This hospital is designed for the prevention of mental disorders; attendance is to be voluntary; and both free consultations and bed care are to be given. Patients are to be examined on the group diagnosis plan, by consulting specialists representing all branches of medicine. An interesting feature is the attempt to remove, by carefully chosen decorations and furnishing, the institutional bleakness too customary in hospitals. It is estimated that there are at least two hundred thousand borderline cases in New York, for whose care no provision is made until some overt act has been committed, bringing the patient before the authorities.

The New York City Cancer Institute

ISAAC LEVIN, M.D.,
New York.

Malignant tumors occupy an anomalous position in the domain of medicine, in respect to both teaching and practice. In the courses of general or special pathology, in the clinical teaching of internal medicine, surgery, or all the clinical specialties, the student is taught something about cancer, but always as a small part of the specialty under discussion and colored by the narrow orientation of the special teacher. The student ends his medical course without having acquired a comprehensive idea of the whole cancer problem, only having gained the impression that cancer of each organ requires a different complicated surgical operation which he as a general practitioner cannot perform. The cancer patients which he meets later in his practice he either sends to a surgeon and loses track of them or when they were operated upon previously he finds them in an advanced stage of the disease and he neither knows how nor has any desire to take care of them. Gradually the practitioner in medicine gains the impression that each individual cancer patient is a person doomed to death, that the general cancer problem is something vague and entirely separated from clinical medicine, and that cancer research is not a part of general biological and medical research but is a blind search for the end of the rainbow in the form of a cancer cure.

A small group of investigators throughout the world began a coordinated study of the cancer problem about a quarter of a century ago and created centres for their investigations. These cancer institutes were and are today of two kinds: They are either laboratories in which experimental studies on malignant tumors in plants or animals are studied without regard to the human patient, or they are hospitals to which only hopeless, far advanced cancer patients are admitted, while the patients in a more hopeful earlier stage of the disease are scattered throughout the general and special hospitals. There is comparatively little coordination between the work of the two types of cancer institutes on one hand and the cancer hospital and the general surgical hospital on the other.

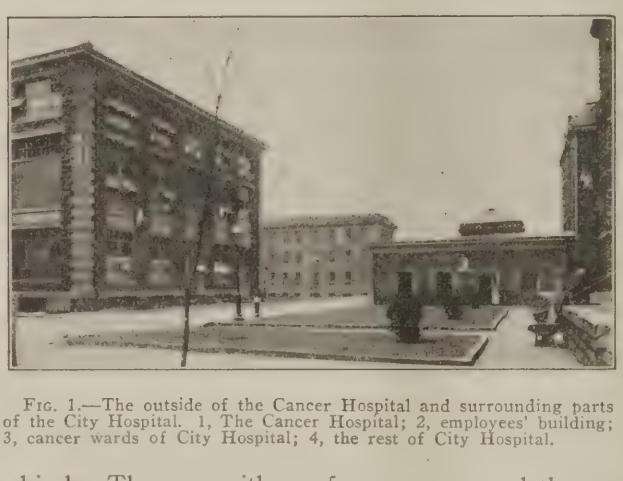


FIG. 1.—The outside of the Cancer Hospital and surrounding parts of the City Hospital. 1, The Cancer Hospital; 2, employees' building; 3, cancer wards of City Hospital; 4, the rest of City Hospital.

For a number of years I have done cancer research in the animal laboratories of the Cancer Research Fund of Columbia University and the Cancer Division of the Montefiore Hospital, but my attempts to coordinate the work of the two institutions have failed.

Mr. Bird S. Coler, the Commissioner of the Department of Public Welfare of the City of New York, who for many years has taken a great interest in the cancer problem from its humanitarian and public welfare aspects, came to the conclusion some years ago that a great municipality such as New York, with six thousand people dying of cancer in a year, must make better provisions for the care of the cancer patients and of the general cancer problem. He also perceived at the outset that the multiplication of effort of the cancer workers and the scattering of the various types of cancer patients into different hospitals retarded the progress in all fields of cancer research.

To obviate these shortcomings Mr. Coler decided not to open an old type cancer hospital or a set of laboratories for cancer research but established the New York City Cancer Institute which is organized on such broad lines that it can take care of all types of cancer patients and is at the same time in a position to conduct every line of cancer research.

THE RESOURCES AND ORGANIZATION OF THE INSTITUTE

The Department of Public Welfare is in charge of the following municipal hospitals: The Metropolitan, City, Central and Neurological Hospitals on Welfare Island, Kings County, Greenpoint, Cumberland and Coney Island Hospitals in Brooklyn, and Sea View Hospital on Staten Island. Their total capacity is nearly ten thousand beds. All these hospitals, as well as many semiprivate hospitals, hitherto took care of the poor of New York City suffering from cancer, and the expenses were charged to the Department of Public Welfare. These patients are now being cared for by the New York City Cancer Institute.

Thus it is clear that the amount of money which the municipality spends on its cancer patients is greater than that devoted by private philanthropy to the same purpose.

The foremost object of the institute is to diagnose, treat and take care of all the poor of New York suffering from cancer. It is divided into three separate units in the following manner:

Cancer patients who present themselves for diagnosis, care and treatment may be roughly divided into three classes.

Class A.—These patients are found upon examination either not to suffer from cancer at all or the disease is in such an early stage that they can be taken care of in the outdoor division or do not require anything but a few days of hospitalization.

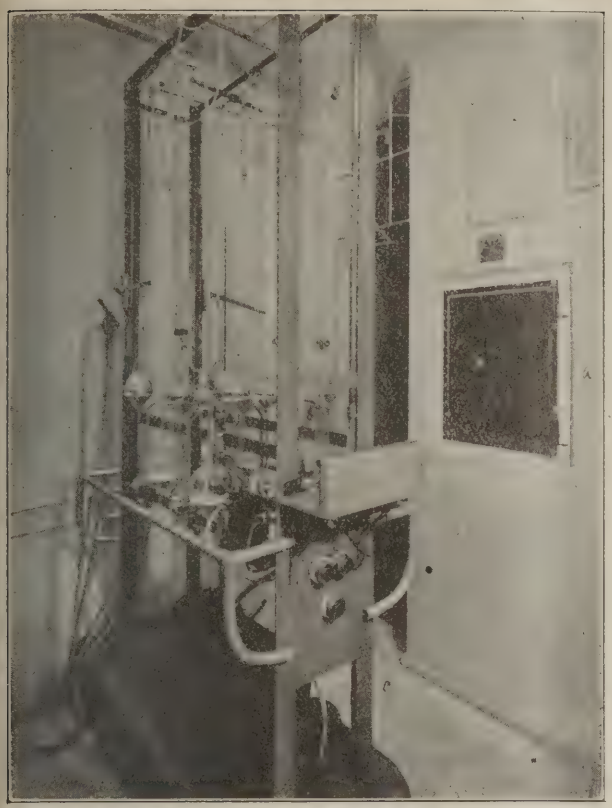

FIG. 2.—A part of the radium laboratories. A, A safe place in a vault which contains the radium in solution. B, Glass tube which connects the radium solution in the safe with the apparatus for pumping and purifying the radium emanation. C, Electric pump used for obtaining vacuum in the glass tubes and glass capillaries.

Class B.—In this class the patients are more seriously ill than those in Class A. They are amenable to treatment but may require several weeks of hospital care.

Class C.—Patients in this class are in a far advanced stage of the disease and cannot obtain more than palliation of the disease and relief of symptoms.

For each group of patients a separate building is used so that in the more severe cases the patients do not produce a depressing effect upon those in a milder state of the disease, and also because, as will be seen later, the three classes of cases present different problems for their care.

The institute is a completely independent medical unit within the Department of Public Welfare. It is aided, however, in its scientific work by all the hospitals of the department, it is affiliated closely with the hospitals on Welfare Island, and particularly with the City Hospital.

Commissioner Coler, of the Department of Public Welfare, gives a great deal of his personal attention to the development and progress of the work of the institute and is assisted in the actual management by Dr. John F. FitzGerald, general medical superintendent of the Department of Public Welfare, Dr. Walter H. Conley, acting general medical superintendent of the Department of Public Welfare, and Dr. Charles B. Bacon, medical superintendent of the City Hospital.

The scientific work is done by the medical director who, with the aid of a staff of associates and assistants, takes care of the surgical, medical and research activities of the institute. All the members of the medical boards of the hospitals of the Department of Public Welfare are consultants to the institute and may be called upon by the medical director to assist in the scientific work.

CANCER CLINIC: CLASS A PATIENTS

This building, situated at 124 East Fifty-ninth Street, Manhattan, is in the most accessible spot from all boroughs of New York City. It is equipped both as a clinic for group diagnosis and for cancer therapy. It is a five story fireproof structure measuring twenty-five by ninety-eight feet. In the basement there is a double high voltage x ray machine for therapy, with complete radiographic and photographic laboratories, and record rooms. On the main floor there is a large general waiting room, with examination rooms for all the specialties, and radium therapy rooms. The third floor contains one male and one female ward with six beds each. The fourth floor contains an operating room, anesthesia and sterilizing rooms, pathological and chemical laboratories for routine work and a conference room. The fifth floor contains kitchen, dining room and service rooms. On the roof is a small animal house for experimental work.

As stated above, in this clinic building diagnosis is made and treatment given, both surgical and radiotherapeutic, provided the patient does not require prolonged hospitalization. This building also serves as a clearing house to which all the cancer patients of the different hospitals are referred.

CANCER HOSPITAL: CLASS B PATIENTS

This building is situated on Welfare Island in close proximity to the City Hospital. To this building patients are transferred who may need a radical surgical operation in conjunction with radium and x ray therapy and who, while they may need prolonged hospitalization, expect to leave the hospital clinically improved or cured.

This building is a three story fireproof structure measuring seventy by ninety feet. The first floor contains record rooms, offices of the social workers,

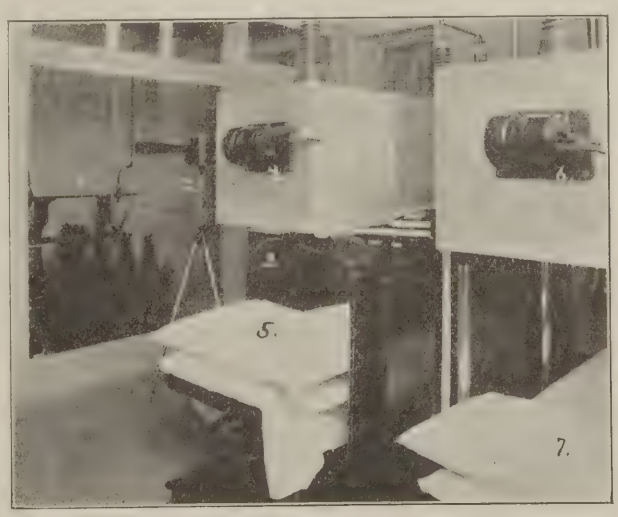

FIG. 3.—A part of the high voltage x ray therapy room. 1, x ray apparatus behind a glass wall; 2, a fine measuring apparatus used for measuring rays coming out from the x ray tube; 3, another measuring apparatus which shows the quantity of rays while the patient is under treatment; 4, a complete lead protected box containing an x ray tube; 5, an adjustable table for placing the patient under treatment; 6, another box containing the second x ray tube, the partition between the two tables is lead protected so as to protect one patient from another.

and a lecture room holding one hundred people. The second floor consists of one male and one female ward of fifteen beds each. On the third floor are a surgical operating room, a sterilizing room, an anesthesia room, rooms for two double high voltage x ray therapy machines and research laboratories in biophysics of radium and x rays.

CANCER WARDS AT CITY HOSPITAL: CLASS C PATIENTS

Unfortunately at present and for some time to come, by far the greatest number of cancer patients who present themselves for treatment are in an advanced stage of the disease, and at the most only palliation and temporary relief of their symptoms can be expected. For these Class C patients two hundred beds are allotted in the wards of the City Hospital. However, these patients may also need major though palliative surgery, radium and x ray treatment. They are being treated at the Cancer Hospital building and then returned to the wards of the City Hospital.

CANCER RESEARCH

I have pursued cancer research in its every phase for over a quarter of a century, on animals and plants and on humans. My opinion to date is that the line of greatest promise is clinical investigation of characteristics, cause and behavior of the different types of cancer and the best methods of therapy for the individual conditions. When animal experimentation is done it should be used only as an adjunct to clinical research. This opinion as regards cancer research is shared by the majority of the investigators of the cancer problem today.

The institute is equipped with laboratories for animal research and for research in pure physics of radioactivity, but the investigations being planned and conducted are applied to clinical problems of cancer therapy.

EDUCATION AND SOCIAL SERVICE WORK

That the only salvation for the cancer patient lies in the early recognition and the early treatment of the disease needs no argument. I consider the campaign of education, both of the profession and the lay public, the most important function of the institute. The mere fact of the existence of the New York City Cancer Institute will help educate the people of this city to the necessity of looking out for the appearance of cancer symptoms. But besides this the institute puts itself into close touch with the Department of Health and the Society for the Control of Cancer in the matter of public education. For the medical profession it conducts frequent clinical conferences and beginning May next it will establish postgraduate courses in diagnosis and treatment of cancer.

The social service work of the institute is so planned that each patient after being discharged from the clinic or hospital will be followed up for years so that a recurrence of the disease may be taken care of before the symptoms could be noticed by the patient.

THE NEED OF MUNICIPAL CANCER INSTITUTES

For the present, the hope and salvation of the cancer patient, particularly the ignorant and the poor, lie in the establishment of large State and municipal institutions for the care and treatment of cancer. These institutes by their mere existence, as stated above, will serve to educate the people, to instill in them confidence in the scientific medical methods of treatment, and to wean them from quackery of all kinds. Such institutions will become, within their own communities, the centres for actual education of both the profession and the public.

It is my firm conviction that Commissioner Coler struck the keynote of the situation in the whole cancer problem when he organized the Cancer Institute within the Department of Public Welfare. Not only will the institute care for all the poor of New York suffering from cancer and will serve as a centre for the education of the people, but one of its main functions will be to train the younger generation of medical men to become experts in the care and treatment of cancer patients and in the cancer problem generally.

Commissioner Coler anticipates that other great municipalities in this country will follow the example set by him and establish similar institutions. The heads of the Health and Welfare Departments of the communties in which such institutes are established and the scientific workers of such institutes should then combine into one large national organization for the Study and Control of Cancer. Such an organization would then be well equipped to approach the solution of the world wide Cancer Problem.

119 West Seventy-first Street.

Foreign Correspondence.

PARIS LETTER

(*From our own correspondent*)

Paris, *May* 14, 1924.

MEDICAL MEN AND SPORT

Sport is occupying a prominent place in the mind of Parisians just now, for the Olympic Games not only are set aside for the French capital, but have actually begun. And during the last few weeks the medical profession has been drawn into the fray. Not that medical men are participating in track and field, but their opinion on sports is being sought on every hand. As a matter of fact, the older school of French practitioner is inclined to ignore sports altogether. Military exercises and Swedish gymnastics are about as far as he has got. Very few have taken to golf, some frequent a *salle d'armes* regularly for a bout with foils, but the great majority pays not the slightest attention to games or sports. And although the French hail Dr. Gosset as a sportsman, his American *confrères* will fail to see how that comes about. Dr. Gosset is chief surgeon of the Salpêtrière and professor at the Paris Faculty of Medicine. Of late he has established a racing stable and his colt Marcellus recently won the Grand Prix du Printemps at Auteuil—hence numerous allusions to his being a sporting surgeon.

ATHLETICS AND THE HEART

Dr. Gosset has rested content with the victory of his colt and has not expressed any opinion on the value or otherwise of athletics. Americans will won-

der why the subject should be discussed at all at this stage, but they should remember that the development of athletics is of recent date in France. The war gave them a very great impetus; before 1914 they were still restricted to the leisured class. Consequently, in this country, it is not considered irrelevant to debate seriously and medically the question: Are sports good or bad? Furthermore, some doctors have come forward to decry athletics. Whereupon Dr. Bellin du Coteau has treated of the question before the Academy of Medicine. He is fully qualified to do so, for not only does he rank high in his profession, but he has held the French championship for 400 mètres flat, has represented his country in previous Olympic Games and has captained the All-France field hockey team. There is no need to dwell long on his paper, as American doctors are familiar with the pros and cons and have made up their minds long ago. Suffice it to say that Dr. Bellin du Coteau showed to the satisfaction of his audience that if hypertrophy of the heart is to be found among athletes, such hypertrophy corresponds merely with that of the biceps, for example, and has no more importance pathologically than the latter. Of course, he assumed that training is carried out in a scientifically progressive manner.

THE GROWTH OF HAIR

Does shaving hasten the growth of hair? This scarcely seems to be a serious medical subject, yet the *Annales de Dermatologie* think it important enough to devote an article thereto. Its purpose, it is true, is to show the fallacy of the popular belief and to dismiss it for all time as of no further interest. With this object in view, Dr. Bulliard recently concluded a series of carefully conducted experiments, during which he proceeded to take accurate measurements, the subject being one of his assistants who, for a period of seven months, appeared in society wearing a black silk skull cap. This was quite essential, seeing that one half of his cranium, longitudinally, was shaved, at regular intervals at first and afterwards at irregular, Dr. Bulliard the while keeping busy with his micrometer. With the data thus obtained graphs were prepared for each side of the skull. The outcome is that although immediately after shaving the pilous growth is stimulated, this effect is of short duration. The final result is identical for the two halves of the head, and there is no appreciable difference, on final analysis, between the length, thickness and density of the hair after a period of months.

FILMING INTERNAL ORGANS

Lomon and Comandon, well known in French scientific circles, have displayed before the Academy of Medicine an invention consisting of an apparatus by which the internal organs of a living person can be cinematographed and thus studied in film projections. The apparatus is not yet developed sufficiently to be placed on the market, but the results up to date are satisfactory and there remain only minor details to be adjusted. The mechanism was evolved in the physical laboratory of the Faculty of Medicine in Paris, a cinematographic camera being adapted for use in conjunction with x rays. The success was such that pictures of the human heart beating were taken at the rate of seventeen images a second. The movements of the lungs and diaphragm were photographed also. The invention, of course, is intended principally to facilitate diagnosis.

VALUE OF WORKS BY AMERICAN SCIENTISTS

Of recent months, it has been rare to peruse a French medical review or even the scientific columns of a daily newspaper without coming across flattering references to works by American physicians or surgeons. At present, for instance, no article on vitamines fails to mention Casimir Funk's volumes published in Baltimore. *The Vitamines* is conceded to be an indispensable work for all those studying the subject, one reviewer remarking that it is "the one book which sets forth all that is known in this connection, and at the same time indicates all the research work that remains to be done." The late Jacques Loeb's *Theory of Colloidal Behavior* is also much talked of, with frank admiration for the genius of the author. French scientists regret that the fiscal situation of the country, necessitating as it does increased customs duties, precludes at present the publication here at reasonable prices of works of the greatest importance. Indeed, the cost of printing has become so high that candidates for the doctorate have been authorized to present theses either in manuscript or manifolded by some mechanical process other than printing.

LONDON LETTER

(From our own correspondent)

London, *May 6, 1924.*

TROPICAL HEALTH SECTION OF THE EMPIRE EXHIBITION

At the Empire Exhibition now being held at Wembley, there is a tropical health department which is intended to give a graphic representation of the various diseases and to explain how they are caused and how they may be prevented. The disease section deals with twenty-seven diseases, and one portion is given over to those which are spread by biting insects. Photographs, pictures, models and specimens are employed to describe each disease, and a brief history and the existing available means for fighting it are also given. Among these diseases are included such maladies as malaria and yellow fever. Another group includes those due to intestinal infections, such as typhoid fever. Food deficiency diseases are represented by scurvy and beriberi. A good deal of space is devoted to skin diseases, yaws and leprosy. The third section deals with hygiene and the fourth with plant diseases. Excellent photographs portray the various stages of sleeping sickness, wax models of the tsetse fly in its developmental stages together with photographs of its haunts and breeding places. The point is strongly emphasized that well organized campaigns against the tsetse fly will stamp out the disease, as witness what has been done in the Isle of Principe. The malaria exhibit is unique in its completeness; models and actual specimens show the stages and processes of breeding and there are models of the parasite in the human and mosquito stages. The manner in which preventive measures are carried out are well demonstrated by the aid of illuminated devices. Yellow

fever is dealt with briefly, a model of the "tiger mosquito," the host of the disease, is shown, and a pictorial account is given of the campaign in Guayaquil recently carried out successfully against this mosquito. The relation of dengue fever to mosquitos is pointed out. A pictorial description is given of the life history of the guinea worm and the various spirochetes causing relapsing fever, syphilis and other diseases are depicted and the manner in which they are propagated is explained. There are photographs and paintings of plague patients and pathological specimens illustrating three varieties of this disease. There are good exhibits of Rocky Mountain fever and Oriental sore and it is shown how recent advances in treatment, as well as in prevention, have made the outlook for these diseases much more hopeful. Dysentery, typhoid and paratyphoid fevers, cholera, hookworm disease and bilharziasis are represented by specimens and descriptions. Scurvy, beriberi, pellagra, and tropical skin diseases, including leprosy, are demonstrated. The relation of scurvy to diet is emphasized by an exhibition of samples on models of various antiscorbutic foodstuffs.

THE AMERICAN HOSPITAL AT HAMPSTEAD

The American Hospital has been opened provisionally in a nursing home at Hampstead, a London suburb, by the American Ambassador. The money in hand will enable the work to be carried on until experience teaches how many beds are needed by the American colony in London. These funds are derived, at least in part, from the unspent balance still in the hands of the Care Committee for Soldiers and Sailors, which was formally handed over to the Provisional Committee of the hospital. A bronze slab accompanied the check to commemorate the work of the Care Committee during the war. All the American organizations in London have cooperated to make the new institution possible, and if the requirements show that a more ambitious hospital is needed, the American colony will be asked to raise enough money to purchase or build such a hospital. More hospital beds are always needed, and London now falls into line with other capitals in having a hospital for its American colony.

GIFTS FOR MEDICAL RESEARCH

The rich men of this country have not compared favorably with those of America in their generosity to medical science. Recently, however, there have been some large gifts to Cambridge University to further medical research, although it must be said that the largest donation for this purpose is from Americans. Mr. and Mrs. P. A. Moltens have added to the previous gifts to Cambridge University by presenting £5,000 to the Moltens Institute of Parasitology to clear off a certain deficit incurred on the building and equipment of the laboratory. Sir Horace and Lady Darwin and Mrs. G. F. Pinsent have given £5,000 to the university to endow research into any problems which bear on mental defects, diseases, or disorders. It is suggested that a Pinsent-Darwin Studentship in Mental Pathology be established in memory of their sons who died in the war. This studentship will be open to both men and women. But the largest gift that the university has received is from the Trustees of the Rockefeller Foundation, who have offered to provide £100,000 for a building for the School of Pathology and £33,000 towards its endowment, provided the university can obtain the remaining £33,000 which is considered necessary for the completion of the endowment. Not long ago the Rockefeller Foundation gave a large sum to the University of London. More recently it gave £75,000 to the University of Oxford for a School of Biochemistry.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION

The provisional program of the ninety-second annual meeting of the British Medical Association to be held at Bradford from July 22d to 25th has been issued. The incoming president will deliver his address on July 22d. The annual representative meeting will begin on July 18th, and be continued on the three following week days. The annual dinner of the association will take place on July 24th. The conferences of secretaries will be held on July 23d. A popular lecture on the sun cure will be delivered by Sir Henry Gauvarn, M.D., on July 25th. July 26th, the last day of the meeting, will be given up to excursions to places of interest in the neighborhood.

ANNUAL CONFERENCE ON TUBERCULOSIS

The tenth annual conference on tuberculosis of the National Association for the Prevention of Tuberculosis will be held in London on July 3d and 4th. The main subject under consideration will be the part played by training colonies in the treatment of tuberculosis, and the conference will take the form of a practical demonstration of the work carried out at the training colony founded and maintained by the national association.

LABOR VIEW OF THE HOSPITAL SITUATION

The following is a summary of the labor view of the hospital situation in Great Britain: 1. The labor movement recognizing the importance of health to individual and national well being, considers that all hospitals, both special and general, together with allied institutions, should be so organized under one authority as to form the foundation on which a complete hospital system for the nation with sufficient accommodation to deal with all cases requiring institutional treatment can be built. 2. It would establish treatment centres in outlying districts, local or cottage hospitals in the smaller towns, one or more county hospitals conveniently situated in each public health area, and national hospitals in London, Edinburgh and other university towns. 3. It would organize intimate cooperation between all the hospitals in each public health area and also between them and the nearest national hospital. It would make arrangements for easy and rapid transference of patients from one hospital to another according to the nature and requirements of the case. 4. It would organize intimate cooperation between the medical staffs of the various hospitals and also between them and general practitioners making the participation of the latter an essential feature of the hospital scheme. 5.It would provide the health authorities with sufficient beds under their own control to deal with all patients for whom they have already undertaken the responsibility. (Patients suffering from tuberculosis or venereal diseases; children from

the school clinics; mothers and infants from the maternity and child welfare centres; and adults under the National Health Insurance scheme.) 6. It would introduce the necessary legislation for the transference of the Poor Law infirmaries from the guardians of the poor to the local health authorities, thus placing at their disposal many beds now vacant. It would remodel these infirmaries where necessary, equipping and conducting them in every way on the lines of the best existing general hospitals.

GONORRHEA IN WOMEN AND CHILDREN

William Heinemann, Ltd., London, have just published a handy and cheap little book on gonorrhea in women and children, being a series of lectures on this subject given by J. Johnston Abraham, C.B.E., D.S.O., M.A., M.D. (Dub.), F.R.C.S. (Eng.), surgeon the London Lock Hospital. It presents the subject in a condensed form but contains the essential points.

VIENNA LETTER

(From our own correspondent)

VIENNA, *April* 1, 1924.

THE FASHION OF DEATH MASKS

A Vienna sculptor, who had very little to do, inserted an advertisement in a leading daily announcing that he prepared death masks—in vito. The novelty created a real craze, resulting in the fact that the artist, who could not make his living from true art, is now so busy with making death masks that he employs twelve men who do nothing else. Society ladies are besieging his studio and compete with each other in having death masks made first. They find it interesting to place their death masks beside those of Beethoven and Nietzsche. Nominally, the technic of making the mask consists in smearing the face with a thick layer of a kind of grease, to save the skin, the eyebrows, the eyelashes and the lips from injury when the plaster cast is removed. A glass tube is placed in the mouth to enable them to breathe. They put wadding in their ears and a silk ribbon is tied on the forehead and the cheeks, which serve to raise the hard plaster that covers the face. Although the whole sitting does not last longer than fifteen minutes, they suffer from unpleasant sensations, difficult breathing, palpitation, and fright. The sculptor has received an invitation to visit Paris, where society ladies are anxiously awaiting him.

SEXUAL SCANDALS IN VIENNA

In the Austrian metropolis the main topic of conversation is the scandalous orgies that it is said took place in the house of a society woman in the villa quarter of Vienna. The charge against her is that she had allowed men to visit her house, where they had rendezvouz with small girls and had committed with them all possible perversities from masochism to sadism, from hypnosis to homosexualism. Among the visitors to this vile place there were gentlemen in high positions and of very high social standing. The Vienna press has presented the details of this scandal in a very objectionable way, which offends public morals. They write openly that undeveloped girls were enticed into this house. Men went there and tormented the bodies of these undeveloped children with lashes, sticks, whips, etc., in order to satisfy their morbid sexual feelings. In one daily paper of eight pages, five pages were taken up with the details of this scandal. Large headlines appeared with such titles as "Intimate details. The confession of the servant girl about the sexual life of her mistress. The most discreet details revealed," and the subject is enlarged upon in a score of columns. After such publications it was only natural that the police intervened. The owner of the house simulated insanity in order to evade the trial, but in vain. The trial revealed still more compromising details than were ventilated in the daily press. A bank director had enticed young boys into his house and had persuaded them to have intercourse one with the other, while he himself, dressed in the mask of a dog, ran around them barking. There was no end to the scandalous and nefarious bestialities, which, thanks to the alertness of the detectives all came to light. It is quite certain that the strictest possible punishments will be meted out to these criminals. Some papers have attacked even the judges, saying that they seem to dig out the minutest details of the scandalous affairs with a seeming delight. They have scrutinized such things, the paper says, that have nothing to do with the merits of the case. They always asked the accused women what drives them to make love to other women? The answer in general is that they were led by curiosity towards the sexual aberrations rather than by objectively weighing the crimes.

The medical journals are searching for the cause of this scandal. They uniformly state that "The community is sick; its press is sick, as well as its literature." They argue that "after the war the city collapsed, and civilian morals were buried with it."

AUSTRIA AND THE FOREIGN MEDICAL DIPLOMATS

On account of numerous inquiries at the Ministry of International Affairs as to the necessary formalities for a foreigner to practise medicine in Austria, the minister has reached a decision. Only diplomas issued by the Austrian universities and foreign diplomas which are granted by passing the necessary examinations before an Austrian university entitle one to practice medicine in Austria. Foreign diplomas which enable one to practice only a certain branch of the medical sciences cannot be accepted. According to the decision of the minister in private life and social intercourse the foreign doctors may use their doctor title, but this does not entitle them, from a legal point of view, to use their title in court, or in the commercial life as long as their diploma is officially accepted and recognized.

SMALLPOX BLINDNESS

Lately it has been intimated that compulsory vaccination should in some measure be mitigated. One of the chief advocates of this erroneous idea is Grottjahn, who appears to be a great apostle of the liberty of man. Contrary to this, Professor Hess has compiled the statistics of the blind people who contracted blindness in consequence of smallpox. From these statistics it is clearly seen that in those lands where there is no compulsory vaccination, the number of blind persons is enormously greater in comparison to states where there is compulsory vaccination in the first year of life.

Book Reviews

UROLOGY

Modern Urology. In original contributions by American Authors Edited by HUGH CABOT, M.D., C.M.G., F.A.C.S. In Two Volumes. Volume I. General Considerations, Diseases of Penis and Urethra, Diseases of Scrotum and Testicle, Diseases of Prostate and Seminal Vesicles. Illustrated with 398 engravings and 11 plates. Volume II. Diseases of the Bladder, Diseases of the Ureter, Diseases of the Kidney. Illustrated with 288 engravings and 8 plates. Second Edition, thoroughly revised. Philadelphia and New York: Lea & Febiger, 1924. Volume I. Pp. xi-828; Volume II. Pp. viii-744.

Modern Urology, in two volumes, is all that its name implies. In reviewing a new book in medicine, the reviewer at once usually sets out to ascertain how up to date the book is. He looks for phases of the subject, as measured by modern standards, that may be for some reason or another left out. As to the work in question, it is extremely gratifying to note that it is difficult to find any such sins of omission, or at least any of great importance.

There is little in the way of destructive criticism to be said. In the chapter on tumors of the testicle, it would seem the author lays rather too much stress on the radical removal of the retroperitoneal iliac and spermatic lymph nodes. This is a procedure of some magnitude, and in the light of the immense amount of good that is accomplished nowadays by radium and deep x ray therapy, such a radical operation is perhaps unwarranted. The author mentions the employment of these measures in connection with the operation and admits their value for glands that may be overlooked in the operation. We think that if radium, for example, is capable of suppressing the advance of malignancy in a few glands that may have been missed, it is reasonable to suppose that it is equally capable of controlling all glands in this region that represent potential foci of malignancy. In this chapter, the author also advocates puncture drainage of the vaginalis. This is done to reduce the amount of hydrocele fluid surrounding a possible malignant growth of the testicle, thereby better enabling one to palpate the latter for diagnostic purposes. Despite the greatest care, it would seem a needle would occasionally strike the growth itself and so disseminate malignant cells.

While the chapter on kidney tumors is excellent, there are too few cuts illustrative of diagnosis by pyelography. The author's description of the types of kidney pelves encountered in tumors, as shown by pyelograms, is admirable, but we fear it would be difficult for the uninitiated, without illustrations, to draw the proper conclusions from many of the bizarre shaped pelves that result from tumors.

The outstanding features of excellence in this work are far too numerous to mention in a brief review. Notable among them, however, is the portion on tumors of the testicle, which deals with their classification and pathology. The latter phase of testicular neoplasms, usually so confusing, is presented in an exceptionally clear and straightforward manner. In the chapter on prostatic obstruction, much stress is laid on gradual bladder decompression and a very clear description of a method of doing this is given. A feature, which is all too often slighted in many urological books, is the tabetic bladder. Here it gets the prominence it deserves. The cystoscopic picture is very graphically and accurately drawn. The chapters on tumors of the bladder and prostate, aside from their interest in general, are noteworthy in showing the strides made by radium therapy. This is particularly true of carcinomata of the bladder.

Stricture of the ureter is handled by the pioneer in this line of work. His work is mostly on women and hence facilitated by the use of the Kelly cystoscope but he points out the fact that with the modern Nitze type of instrument, there is no excuse for not doing just as much investigation along this line as in the male. The chapter on tests of renal function is unusually complete, and contains a description of simplified practical methods of doing blood chemistry. The latter has come into its own in recent years in urology, but proper descriptive methods are lacking in most genitourinary works.

In general, these two volumes are admirably arranged. Diseases of the bladder, diseases of the ureter and diseases of the kidney represent the three divisions of volume No. II, while generalities and all other urological conditions are grouped together in volume No. I. The bibliography in each chapter is very comprehensive and very conveniently arranged at the end of the chapter.

VENEREAL DISEASES

Venereal Disease, Its Prevention, Symptoms, and Treatment. By HUGH WANSEY BAYLY, M.C., Hon. Sec. Society for the Prevention of Venereal Disease. Second Edition, with Fifty-five Illustrations. London: J. & A. Churchill; New York: MacMillan Company, 1924. Pp. 170.

This compact volume deals with the salient points with regard to the prevention, symptoms, and treatment of venereal disease. This is a second edition carefully revised in such a way that, although smaller than the former edition, it contains the main facts in connection with modern treatment, special stress being laid upon the preventive aspect. The author who is the honorary secretary of the British Society for the Prevention of Venereal Disease, is not only an authority on the subject, but as secretary of the above society, has been chiefly responsible perhaps for insistently emphasizing the truth that in the treatment of venereal disease the old adage, prevention is better than cure, applies with especial force. Moreover, this society advocates an effective means of prevention and for some years past has been endeavoring to educate the public and to bring the medical profession to its way of thinking. While there is still difference of opinion among experts on venereal disease as to methods of prevention, a great deal of the prejudice which has existed against immediate self disinfection, one of the weapons advocated by the society, appears to be waning in Great Britain. Of course it is felt and acknowledged by all, that if success is to be reached, the profession must be united in any campaign against so insidious and devastating a plague as venereal disease, which, after all, is as much of a social as a medical problem.

Therefore an educative crusade conducted on sane and rational lines is essential. All this is explained in the preface by the author, who also enters into certain matters in connection with the policy of the society which arose during Dr. Bayly's candidature for Parliament for one of the Plymouth Divisions against Lady Astor. The preface should be read carefully.

The book itself is an admirably arranged, judiciously condensed manual of venereal disease. All that is really important is included. Dr. Bayly insists that venereal disease is the most easily controlled of all the chronic infections, provided that it is grappled with promptly and effectively. He deplores the policy of refusing to face the problem boldly, a policy which he and many others believe has led to the wide dissemination of venereal infection. As said before, the author suggests ways and means for stemming this spread, and consequently the book is of interest to those concerned in the biggest international medical and social question of all time.

CIRCULATORY DISTURBANCES OF THE EXTREMITIES

The Circulatory Disturbances of the Extremities. Including Gangrene, Vasomotor and Trophic Disorders. By Leo Buerger, M.A., M.D. With 188 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Pp. 628.

The circulatory disturbances of the extremities form a very unsatisfactory chapter in clinical medicine. Encountered with great frequency by the general practitioner, internist and surgeon, they nevertheless offer many difficulties in diagnosis, and demand mature judgment in their treatment. It is fortunate, therefore, that Dr. Buerger, who has had such a rich experience in the study of disease, and who has made some fundamental contributions to our knowledge in this domain of medicine, has found time to prepare this monograph. There is no other book that covers the field exhaustively.

The first hundred pages of the book are devoted to an exposition of the anatomy, physiology and pathological physiology of the circulation of the extremities. Considerable attention is devoted to the vasomotor nervous mechanism. There follow several chapters on diagnostic symptoms. Intermittent claudication is discussed at length. A number of chapters are devoted to the various types of gangrene. One hundred and seventy pages are devoted to a thorough description of the clinical and pathological picture of thromboangiitis obliterans. This, as is to be expected, is the best section of the book, although the chapters on arteriosclerosis of the arteries of the extremities are excellent.

The rest of the volume is devoted to a presentation of a great variety of circulatory disturbances of the extremities, such as Raynaud's disease, erythromelalgia, and the vasomotor neuroses. Finally, there is a brief review of the results obtained by the newer methods of capillary microscopy.

The illustrations, of which there are one hundred and ninety-two, are well selected and well reproduced. The bibliography, which is quite complete, will be found valuable by the reader who wishes to consult the original literature. Many illustrative case histories are presented.

It is unfortunate that the author has subdivided the book into one hundred and eight chapters, many of which are no more than one page long. A rearrangement of the material would improve the book. Similarly, the style, which is often of loose construction, with very long sentences, disturbs the fastidious reader.

There is a distinct need in American literature for more monographs of this sort, which are not mere compilations of the literature, but which represent the fruits of the author's wide experience in a special field, and in which the subject matter is handled in a comprehensive and critical manner.

LOCAL ANESTHESIA

Local Anesthesia. Its Scientific Basis and Practical Use. By Prof. Dr. H. Braun, Zwickau, Germany. Revised sixth edition. Translated and edited by Malcolm L. Harris, M.D. With 231 illustrations in black and colors. Philadelphia and New York: Lea & Febiger, 1924. Pp. 411.

Braun's *Local Anesthesia* has been the standard German work on this subject since the appearance of the first edition in 1905. The third edition was translated into English in 1914 by Dr. P. Shields, of Chicago. As stated in the introduction, the sixth edition contains so much new matter and so much of the old has been rewritten in the light of more extended experience that the need of an entirely new translation was evident. In the translation Dr. Harris has adhered strictly to the text except where his notes clearly indicate to the contrary.

Dr. Braun confines himself exclusively to local anesthesia. His clinical experience has been extensive and his book is written in a practical way without minimizing the importance of a thorough knowledge of the scientific basis of the subject. The first ten chapters are devoted to the history, development and pharmacology of the modern local anesthetic agents. He gives the various methods of using the local anesthetic drugs and the general technic of infiltration, conduction, lumbar and sacral anesthesia. He outlines more clearly the indications, contraindications and limitations of local anesthesia. In the last six chapters he considers regionally all portions of the body and the practical use of local anesthesia in the special branches such as ophthalmology, otology, rhinology, gynecology and urology. Many operations are described with the aid of illustrations and actual photographs taken during the operations in order to demonstrate the possibilities of local anesthesia and the value of a better understanding of the technic. Surgeons who employ local anesthesia should not fail to study this work.

DIETETICS

Diet for Children (and Adults). By Lulu Hunt Peters, A.B., M.D. New York: Dodd Mead & Co., 1924. Pp. 313.

Readers could hardly fail to be benefited by studying this book of slightly more than three hundred pages. Information contained within its pages is gathered from the writings of pediatrists. It is up to date in respect to vitamines, minerals, and balance in diet. It is not difficult for the layman to understand. The menus and receipes are plentiful. The first half of the book is devoted to the normal infant and child and as the author says "the diets given for

the child are just as good for the adult." This includes part one and part two. Part three discusses diet in disease and includes some advice regarding bad habits. Part four relates to food poisonings. Part five consists of drawings, accompanied by rhymes for the amusement and instruction of children on the subject of diet, with the Kalorie Kids.

HEREDITY AND EUGENICS

Handbuch der biologischen Arbeitsmethoden. Unter Mitarbeit von 500 bedeutenden Fachmännern, herausgegeben von Geh. Med.-Rat. PROF. DR. EMIL ABDERHALDEN Direktor des Physiologischen Institutes der Universität Halle a. d. Saale. Abt. IX, Methoden zur Erforschung der Leistungen des tierischen Organismus, Teil 3, Heft 1. Methoden der Vererbungsforschung. Berlin und Wein: Urban & Schwarzenberg, 1923. Pp. 210.

This is a highly technical study of the subject of heredity. Julius Bauer discusses the methods of studying the constitution of individuals. Paul Kammerer dilates upon the methods of studying the heredity of acquired properties and those of studying experimental variations. Valentin Haecker is assigned the subject of the methods of studying heredity in man. Robert Sommer deals with the subject of the methods used in studying the hereditary characteristics of families. This series of articles is of interest only to those engaged in investigating the subject of heredity and eugenics.

THE HUMANITIES

Humanidades. Publicacion de la Facultad de Humanidades y Ciencias de la Educacion. Dirigida por RICARDO LEVENE.

This is a publication of the National University of La Plata, Argentine Republic, from the Faculty of Liberal Arts and Science of Education. There are articles on The Argentine Writer and Castilian Grammar, on World Peace, on Liberalism and Humanism in the Problems of the Present Day, on Notes on the Ethical Problem in the Theories of Aristotle, and like subjects.

The present volume is the sixth of a series and bears the date 1923, but one does not learn from its contents whether or not it is an annual publication. At the beginning of the text there is set forth a list of the officers of the university as well as the names of the Faculty under whose auspices the publication is prepared and issued.

Its interest necessarily must be primarily for the educator and the scholar rather than for the professional man.

"FAR AWAY AND LONG AGO"

The Bridal Wreath. By SIGRID UNDSET. Translated from the Norwegian by C. Archer and J. S. Scott. New York: Alfred A. Knopf, 1923.

To give new warmth and life to characters dead since the fourteenth century requires more than ordinary skill. In *The Bridal Wreath,* Sigrid Undset has unfolded a simpler tale than in her *Jenny,* but just as powerful and even more highly colored. We are reminded that after all human nature does not change much. And at the same time there is no sense of modern intrusion. Kristin Lavransdatter grows from child to woman according to the pattern of unending time. The fundamentals are still the same. Only in the rich detail of her life does it differ from one's own. Miss Undset's picture of the "far away and long ago" makes us yearn for the simple life when beautiful things were handwrought; we tend to forget that the beautiful souls of that time were supposedly the work of the churches. Kristin takes her own soul in hand, and thus bridges many centuries.

TOLD BY AN IDIOT

Told by an Idiot. By ROSE MACAULAY. New York: Boni and Liveright, 1924.

There is nothing new under the sun. This theme is iterated and reiterated almost to tiresomeness in Miss Macaulay's latest book. The story is excellent on many counts; as history, as a politicosocioeconomic study, as satire, as workmanship. But—it isn't a story. It is life. Yet one feels a hiatus in the shaping of this life to fictional ends. Even Galsworthy has had better success with the three generation chronicle. Gilbert Cannan still has an excellent one in the making. Thomas Mann in *Buddenbrook* gives us the German classic, and Knut Hamsun speaks for Scandinavia in the two volumes pertaining to Segelfoss. It seems to be an age of chronicles. If only Miss Macaulay had got a little ahead of the tide, or a little behind. As it is, she is slightly eclipsed on her share of the life of man by *The Long Journey.* We wish we could praise the book more highly. After its noisy réclame we had high hopes, and were distinctly disappointed. There are excellent characterizations, good psychology, valuable documentary history on 1870 life and manners. But the heart of it does not beat. One feels the straining for vivacity. It almost lives—and then the infant drama is overlaid by wads of politics!

A MYSTERY TALE

The Shot. By SIBYL CREED. London: Chatts and Windus; New York: Doran Co., 1924.

This book, although essentially a mystery tale, is at the same time somewhat out of the common. Most mystery tales are not well written, that is to say, are not good literature. *The Shot* is an exception, for while the plot is all it should be, the phrasing and language are exceptionally well done. The plot is the thing and the plot is extremely ingenious and holds the reader's attention until its unfolding. As an excellent mystery story is rightly expected to be, the plot is not intricate and confusing, but natural and simple and fits in with the circumstances. The tale is both exciting and homely and is told in a curiously effective manner, a manner which is interesting and attractive. A feature of the book, outside of the plot, is the description of Thames side scenery. These are delicately drawn vignettes of the district of which Miss Creed writes. The author is no less at home in her sketches of character, which are drawn with a sure but discriminating hand. From the viewpoints of plot and literary merit the book is on a high plane.

MARRIAGE

The Marriage Verdict. By FRANK H. SPEARMAN. New York: Charles Scribner's & Son, 1923.

Here is a beautiful lady disastrously married to a ruffian. The war, suffering, and divorce, and finally —*the* man. But our heroine in the interim has become a Catholic! And yet the last pages see the lovers united by the Bishop. How it is done is logically and skillfully unfolded.

Medicoliterary Notes.

Gora is the title of a new novel by Rabindranath Tagore, lately published by the London branch of Macmillan. It is not only an interesting and brilliantly told story, but a revelation and interpretation of the heart and soul of India. The fundamental understanding and harmony that should and does underlie, according to Tagore, the differences of nations and races, of East and West—Mr. Kipling to the contrary—is emphasized in the climax of the novel, the discovery that the Hindu patriot and leader of the extreme pronative political school, is really a man of pure British blood who was adopted at birth by an Indian family and brought up in the traditions of the East.

* * *

The Three Impostors, by Arthur Machen, is a real "thriller" for all who enjoy stories of mystery, black magic and occultism. It is well written, with the exception of one or two violations of good taste in attaining the horrible, and has a delightful undercurrent of humor for those who can find it. H. Rider Haggard has given us recently another Allan Quatermain tale in *Heu-Heu, or the Monster,* which describes a long, wild journey into a forgotten corner of Africa for the purpose of rescuing a beautiful maiden from a tribe of primitive men worshipping a weird devil-ghost.

* * *

A late issue of the *North American Review* contains an amusing article entitled "The Problem of the Darned Fool," which is a statement of a minister's opinion of presentday mental incompetence. The writer, Rev. Mitchell Bronk, lists among signs of this incompetence, Laura Jean Libbey's books, inane "movies," gold brick experts, clairvoyants, crowding on the subway, jazz, and so on ad infinitum. But he suggests no cure!

* * *

A comprehensive and exceedingly well classified *Bibliography of Eugenics,* compiled by Prof. S. J. Holmes, of the department of zoology of the University of California, has recently been issued as volume 25 of the university's *Publications in Zoology.* The titles are listed under thirty-nine subdivisions of the subject.

* * *

The *Physician and the People,* by Dr. Leonard L. Landis, gives an account of why its author broke away from the "hidebound medical traditions" in which he was brought up, and established for himself and his practice a new foundation principle which he calls "democracy in medicine."

* * *

Patricia's Awakening is the title of a first novel by Harold J. Barrett, who conducts a successful daily business column, "Dollars and Sense," in various American newspapers. His novel describes the modus operandi of this venture.

* * *

The Committee on Publicity Methods in Social Work has recently awarded the prize of $250 offered by Walter May, a Pittsburgh druggist greatly interested in social work. The recipient was Miss Eleanor R. Wembridge, of the Women's Protective Association of Cleveland, O., and the title of her play is *The First of May.* This play together with another that received honorable mention—*A Horse Shoe-Nail,* by Miss Frances B. Williams, of the National Child Labor Committee, New York City,—will be produced in Toronto at the June National Conference of Social Work in that city. The plays cover ideas in public health, race relations, child welfare, and other social fields, and were judged for their dramatic value as well as for their social message.

* * *

The Living Age for May 24th contains a number of interesting biographical sketches, namely, How Tolstoi Died; A Secret Police Report, by General Lvov, chief of police of the Moscow district; Mussolini, a Man of Many Interests, by Yoi Maraini, from the English *Saturday Review,* and Memories of Saint-Saens, by Falerio, from *La Revue Mondiale* of Paris. Sigrid Bugge Westmarr writes of her experiences as "A Nurse Among the Eskimos." The book review section is of unusual interest, including as it does reviews of Roman Rolland's *Mahatma Gandhi,* published by the Century Company; *La Guerre des Femmes: Histoire de Louise de Bettignies et de ses Compagnes,* by Antoine Redier, the story of a woman who during the World War organized an efficient intelligence service, crossed the German lines twenty times, was captured, imprisoned, tried, court-martialed, sentenced to death, reprieved and resentenced to life imprisonment, and who finally died after two years of prison and was buried with military and other high honors; *The Pirates' Who's Who;* giving particulars of the lives and deaths of the pirates and buccaneers, by Philip Gosse; and *Islam and the Psychology of the Musulman,* by Andre Servier, published by Chapman and Hall of London.

* * *

Now that Robert Frost, whose volume of verse, *New Hampshire,* won the Pulitzer prize for the best volume of verse published in 1923, has become so well known as one of the foremost poets of the United States, it will come as a surprise to many that he had to go to England to be appreciated. For years he wrote poems that he could not sell, meanwhile eking out a livelihood for his family by working a barren New England farm. This he finally sold, taking his family to England on the proceeds. Apparently America did not miss him—but when three years later he returned, with English laurels on his brow, she welcomed him with open arms and acclaimed him her most famous poet.

* * *

The Russian Health Ministry reports that from forty to seventy per cent. of the homeless children of that country in the larger cities are cocaine and alcohol addicts, and estimates that the vagrant children of Moscow and its suburbs alone number about fifty thousand. This evil of child vagrancy has been caused by the late famines.

* * *

The daily press has announced the closing by the local Turkish authorities of the Medical Department of the Constantinople College for Women. This college has only recently completed the building of a new medical headquarters and laboratories. Dr. Wilfred Post, of Princeton, was dean of the School of Medicine and Surgery. The Turkish police reported that they were acting under instructions from the Ministry of Public Instruction.

* * *

At a primary school examination, one of the questions was on the five senses. A pupil wrote: "The five senses are sneezing, sobbing, crying, yawning, coughing. By the sixth sense is meant an extra one which some folks have. This is snoring."—*Boston Transcript.*

* * *

Agriculturists in France are using fish flour. This is made from nonedible fish found in the nets of trawlers, and is exported to Germany, Spain and Switzerland. It is very rich in proteids and phosphates and is mixed with the food of poultry, rabbits, dogs, sheep, cattle and hogs. It is said to greatly increase the flow of milk and the laying of eggs.

* * *

How to be happy, though civilized, has become the most insistent problem of contemporary life.—*Clayton Hamilton in The Century.*

* * *

A labor university is to be founded in Santiago, Chili, by the municipal government through the efforts of the mayor of the city. The aims of the university will be to educate and train working men and women in trades most suitable to their natural abilities.—*Monthly Labor Review.*

* * *

Dr. Matthias Nicoll, State Commissioner of Health, in a radio talk recently broadcast, commented drastically on the immediate need for further automobile legislation. Dr. Nicoll said: "If a modern car of Juggernaut should travel with the speed of an express train from Maine to California and leave in its wake 16,000 men, women, and children crushed or burned to death, and 400,000 more crippled and bruised, the people of this country would be horrified and aroused to make every effort to stop this inhuman slaughter; yet just this thing happened in the United States in 1923, except that several thousand little Juggernauts did the work over a longer period of time. So accustomed have we become to reading in the daily press the accounts of automobile accidents that we have grown more or less indifferent and inclined to accept them as a matter of course. This attitude of mind on the part of the public will get us nowhere in lowering the daily butcher's bill."

Abstracts from Current Literature

GENITOURINARY DISORDERS

A New Mercurial (Flumerin) for the Intravenous Treatment of Syphilis.—W. R. Snodgrass (*Lancet,* January 19, 1924) reports his results with flumerin given intravenously in twenty-five cases of syphilis. The vast majority of the injections were well borne and the side effects were no worse than those following any other intravenous mercurial. Flumerin should be used carefully but it is not contraindicated because of its toxicity. The following conclusions are drawn: 1. Gross secondary lesions show material alteration in the direction of healing within one week as a result of the administration of flumerin alone. No other mercurial preparation would appear to produce marked changes so rapidly. 2. The action is not lasting. Relapses in secondary cases may occur within a relatively short time even while treatment by flumerin is being continued. 3. A positive Wassermann reaction is usually not altered to a negative one. In this respect flumerin does not compare unfavorably with an equivalent use of other mercurials given without arsphenamine preparations. 4. Tertiary cases which present definite lesions show rapid clinical improvement with flumerin alone. The rapidity appears much greater than that produced by other mercurials but less than by combined treatment by mercury and iodide. No effect upon the Wassermann reaction was noted. This is not significant in view of the duration of treatment. 5. Marked toxic effects of the nature of acute mercurialism were occasionally seen. Conversely, cases of great toleration were noted. The reason for this is apparently not related to the patient's general physical condition. 6. Extended trial of flumerin should be made on account of its rapid antisyphilitic effect. This rapidity is its outstanding property. At the same time, even the restricted observations of the author indicate clearly that the drug should be used along with arsphenamine or iodides, as the case demands.

Treatment of Neurosyphilis with Sulpharsphenamine.—R. D. Halloran (*Boston Medical and Surgical Journal,* January 10, 1924) says that sulpharsphenamine is extremely simple of preparation and administration. It has a comparative freedom from local and general reactions. It may be administered intramuscularly without ill effects. The symptoms of renal irritation following several treatments are not satisfactorily explained; they may be due to excessive doses or to a cumulative toxic effect upon the kidney. The production of glycosuria in one case is not explained. An acute iritis developed in one case, which may have been due indirectly to the treatment. The spinal fluid changes compare favorably with those produced by the arsphenamines. There seems to be a certain uniformity and rapidity of alteration of diagnostic standards in advanced, unselected cases which have not been noted with other forms of treatment. This may indicate a greater toxicity of sulpharsphenamine for the spirochetes of the central nervous system.

Importance of Functional Tests in the Diagnosis of Surgical Diseases of the Kidney.—F. Suter (*Schweizerische medizinische Wochenschrift,* January 10, 1924) reviews his results in a series of 1000 renal functional tests, 396 of which were controlled by operation. The use of cryoscopy is important, but it has only a relative value. The indigocarmin test was always done in combination with catheterization of the ureters and failures were never encountered. The phenolsulphonephthalein test was found to be less reliable. The author prefers to use the combination of careful microscopical and chemical examination of the urine, cryoscopy and the indigocarmin test, as any single one of these tests is likely to fail in a given case. In difficult borderline cases, the indigocarmine test never failed the author and he never observed a single renal death in 302 nephrectomies after this test. In such cases cryoscopy of the blood, the determination of the residual nitrogen and possibly the Volhard concentration and dilution tests (as preliminary tests) are of special value. In cases of prostatic hypertrophy with possible injury of the kidneys, the concentration power of the kidneys, preceded by preliminary treatment with the indwelling catheter, should be carried out.

Syphilis as a Complication of Tuberculosis.—A. K. Bowman (*Lancet,* December 15, 1923) concludes as follows: 1. From a consideration of limited data the incidence of a positive Wassermann reaction has not been found to be more frequent among the tuberculous than among the general population. 2. Syphilis of the lungs existing as an isolated disease is extremely rare, but it may be that a number of cases recognized as pulmonary tuberculosis, and in which the Wassermann reaction is positive, are in reality cases of combined syphilis and tuberculosis of the lungs. 3. The two diseases when coexistent in the same individual may modify each other. 4. In cases in which syphilis and tuberculosis are present in the same individual, the administration of arsphenamine and its analogues may be followed by disaster. If organic arsenic is used, it should be administered in extremely small doses and at wide intervals. If no disturbance follows the injections, treatment may be continued cautiously, but it should be at least temporarily suspended if focal or general reactions occur and the condition carefully watched. 5. Organic arsenic compounds may be useful in cases in which the diagnosis is doubtful, but it is unjustifiable to employ them for diagnostic purposes save with extreme care, and always having in mind the possibility of a tuberculous flareup.

Technic for the Application of Radium (Emanation) in Carcinoma of the Prostate.—Ernest M. Watson (*Buffalo General Hospital Bulletin,* January, 1924) describes a technic with which it is possible accurately to deposit with the prostate, seminal vesicles and trigone of the bladder, 1500 to 2000 millicuries of radium emanation under novocaine anesthesia in about eight to ten minutes, and without great inconvenience to the patient. At a point along the median raphe about one and one half inches in front of the rectum the skin and subcutaneous tissues are infiltrated with 0.5 to 1.0 per cent. novocaine solution. A needle about four and one half inches long is used to infiltrate the tissues in front of the prostate. With a finger in the rectum as a guide, a medium sized trocar is inserted in the midline of the perineum up to the prostate. After withdrawing the obdurator, needles carrying a small glass tube or seed of emanation are inserted and fifteen to twenty seeds are then placed in different portions of the gland by simply changing the axis of the trocar. The seeds vary in strength from 0.6 to 1.0 millicurie and are placed about 1.0 cm. apart throughout the entire gland as indicated. The involved seminal vesicles may also be reached in this manner by passing the needles through the gland. Enlargements of the middle and lateral prostatic lobes, elevation and infiltration of the lower portion of the trigone, and the rounding and fixation of the anterior commissure may also be seeded without removing the trocar.

Treatment of Tuberculosis of the Urinary Tract.—James R. Macalpine (*British Medical Journal,* January 19, 1924) states that surgical endeavors should be directed to the kidney instead of the bladder. The kidney is primarily at fault and almost invariably the disease is unilateral in its early stages and the bladder is affected secondarily. The other kidney will become affected in a large proportion of cases at a later date, and if the primarily involved organ is removed, the prognosis of the disease will be good, both as regards the bladder, which will heal, and as regards the other kidney, which is not very likely to become secondarily infected. In the absence of contraindications, nephrectomy must be carried out without delay in every case. Gas and oxygen anesthesia is the most suitable, as it does not affect the remaining kidney and does not have a tendency to light up foci of latent tuberculosis in the lungs. The author removes as much of the ureter as can conveniently be taken away from an ordinarily generous loin incision, and he uses the cautery in its division. Usually the upper and lower segments of the ureter are most affected. If the surgeon gets down as far as the beginning of the uninvolved area healing will be just as rapid as if an extra few inches were removed. An exception should be made in ureters which are occluded at some point in their course. If such a ureter be left the portion above the obstruction a sinus in the flank will result. Besides, an obstructed ureter is difficult to remove because of the periuteral and perinephric sclerosis and ureterectomy

should therefore be avoided. It is good practice to drain the wound after nephrectomy even after a complete removal of the kidney. The perinephric fat should also be removed, as it is a common source of subsequent infection. The bladder need no serious consideration, as they usually diminish and eventually disappear after a sufficient lapse of time. In addition to the usual vaccine, tuberculin and hygienic treatment of the postoperative tuberculous bladder, the use of sparking through the high frequency current gives some very good results. *Noli me tangere* may be said to be the watchword in bilateral renal tuberculosis, as ultimately only discredit may be brought on surgery by the use of operative measures in this condition.

Tuberculosis of the Kidney and Renal Functional Tests.—H. Wildbolz (*Schweizerische medizinische Wochenschrift,* January 10, 1924) states that tubercle bacilli may be excreted in the urine without there being any tuberculous disease of the kidneys but in the presence of tuberculosis elsewhere (not only in the seminal vesicles), and therefore functional tests should not be omitted, as they almost always lead to a diagnosis in early cases and also give decisive information in regard to the question of bilateral renal involvement. The presence of tubercle bacilli and leukocytes in the ureteral specimen of urine should not be considered as proof of renal disease, as they also occur in ascending tuberculosis of the ureter with healthy kidney, the function of which may be intact. Diagnostic splitting of the kidney is a dangerous procedure because of the subsequent miliary infection, infection of the wound bed, and great unreliability because small foci remain undiscovered. Pyelography and pneumoröntgenography are dangerous in tuberculosis for the same reasons. The functional test never failed in about five hundred nephrectomies, even in the presence of small tuberculous foci. The use of Ambard's constant, so strongly advocated by the French school, cannot replace functional kidney tests combined with ureteral catheterization. The author considers the indigocarmin test, reinforced by the comparative cryoscopy of the urine from both sides, the comparative determination of urea excretion on both sides and the phloridzin test as the method of choice.

Diagnostic Value of Stalagmometric Examination of the Urine.—Andreas Matusovszky and Alexander Laczka (*Zentralblatt für Gynäkologie,* December 15, 1923) state that the surface tension, the measurement of which was applied to the urine and introduced into gynecology, and which is reduced by the presence of colloid and semicolloid substances, called stalagmones, gave the authors definite results in pregnancy and after anesthesia, as a result of the marked disturbance in the metabolism of albumin and indefinite results in myomas, abscesses, malignant tumors, etc. These stalagmones may also affect the specific gravity of the red blood cells. These interesting variations in the surface tension may be explained by additional investigations on the individual substances which produce them and their relationship with nutritional conditions and conditions of life.

Flocculation Reactions as Substitutes for the Wassermann Test.—F. Green (*Journal of Laboratory and Clinical Medicine,* April, 1924) reviews the various reactions which have been developed for the serodiagnosis of syphilis. He did not find the Sachs-Georgi reaction as sensitive as the Wassermann. The Dreyer and Ward modification of the Sachs-Georgi flocculation reaction was tried on more than 150 sera, and the results compared with the Wassermann test. In view of the simplicity and ease with which this modification may be standardized, granted an increase in its sensitivity and improvement in the matter of reading the results, it may in future very well stand beside the Wassermann reaction.

A Comparative Study of the Wassermann and Meinicke Reactions.—C. B. McGlumphy (*Journal of Laboratory and Clinical Medicine,* April, 1924) describes the preparation of the lipoid extract, the standardization of the extract, dilution of antigen, and the test proper of the Meinicke reaction. A comparative study of this reaction with that of Wassermann was made in 1162 cases. There was a high percentage of agreement of the two reactions. In a small group of cases in which the diagnosis of syphilis was unquestionable, the results obtained by the Meinicke test were superior, as the clinical data furnished conclusive evidence of the value of the Meinicke reaction in certain cases where the Wassermann reaction was negative.

Treatment of Gonorrheal Epididymitis with Intravenous Injections of Calcium Chloride.—Alvin E. Cerf (*Therapeutic Gazette,* March 15, 1924) from an experience of seventeen cases concludes that calcium chloride in ten per cent. solution given intravenously in five or ten c.c. quantities is harmless. It has a decided effect in bringing about rapid subsidence of the swelling in the epididymis, hastens the absorption of the exudate, minimizes the resultant pathology involved in this area. As it apparently greatly increases the resistance of the tissues to bacterial invasion, its early employment is important.

The Status of Epidemic Encephalitis as an Independent Disease.—Peter Bassoe (*Illinois Medical Journal,* February, 1924) admits that in spite of the building up of a varied, yet quite individual, symptomatology, including numerous and very characteristic sequelæ and of definite almost pathognomonic morbid anatomy, nevertheless the position of epidemic encephalitis as a disease *sui generis* is not absolutely secure.

Treatment of Gonorrhea by Intravenous Injections of Acriflavine.—J. R. Jacob and K. V. Verasingam (*Indian Medical Gazette,* February, 1924) report a series of thirty cases treated by this method between July 1st and December 31, 1922. The first ten cases were treated with 1 in 1000 solution and the subsequent twenty with a 1 in 500 solution in normal saline. The first dose was 100 c.c., followed in two days by 150 c.c. and then 200 c.c. at intervals of three to four days. In early cases rapid results are obtained. In cases with acute urethral inflammation, with painful micturition, and local edema with extreme tenderness, all local remedies with attendant pain are obviated. In cases of posterior urethritis the best results are obtained by combining the intravenous method with local treatment.

PEDIATRICS

Treatment of Megacolon in Children.—E. Monnier (*Schweizerische medizinische Wochenschrift,* October 18, 1923) states that the treatment of megacolon must be directed toward the cause of the stasis. The evacuation of the decomposed fecal masses and the resulting avoidance of toxemia is the aim of both the internal and surgical treatments. Treatment with the rectal tube is uncertain, extremely troublesome and possible only in a hospital. The results are more favorable in the spastic cases with the use of atropine. In some cases blunt dilatation of the contracted sphincter is useful. The opium treatment is sometimes successful. However, the mortality with internal treatment is quite considerable.

The surgical treatment may be divided into two groups: 1. Palliative operations, such as colostomy, colopexy, coloplication and the various kinds of exclusions and anastomoses. 2. The second group constitutes the radical procedures, including the various resections of the pathological colon. The palliative procedures have produced some good results, even though they are rather uncertain. In recent years there is a tendency to carry out the palliative operations as preparatory procedures for the radical operations. The best results are obtained when a communication between the cecum and the lower part of the sigmoid flexure is established. The main reason for the unsatisfactory results with the palliative operations is the fact that the dilatation of the colon persists even though a regular passage of stools is obtained. The ideal procedure consists in the resection of a large part of the dilated colon with immediate anastomosis of the two cut surfaces. This operation, however, is applicable only when the general condition of the patient is good and a good emptying of the colon is possible.

Children's Upper Respiratory Abscesses Descending into the Neck and Mediastinum.—Otto Glogau (*Archives of Pediatrics,* December, 1923) states that in childhood, abscesses within the upper respiratory and alimentary tracts occur frequently and may easily descend by way of the regional lymph vessels and glands into the parapharyngeal, retropharyngeal and retroesophageal loose connective tissue spaces, causing phlegmon of the neck and descending alongside the vascular sheath into the mediastinum, causing mediastinitis, sepsis and death. However, with the swelling in the neck increasing in size and becoming more tender and disclosed, with the occurrence of pains in the region of the jugulum and the appearance of severe general symptoms, the typical external operation should be resorted to.

It consists of a wide exposure of the vascular sheath and of the direct opening and draining from there of the parapharyngeal, retropharyngeal and retroesophageal spaces. These deep descending abscesses frequently are complicated by suppurating glands intimately connected with the jugular vein, which may be extended like a flask; they can hardly be reached by simple incision from without or within, without endangering the life of the child from puncturing the large vessels, especially the external jugular vein. In severe cases, where mediastinitis is threatening or present, the anterior and posterior collar mediastinum is exposed; it is sealed with iodoform gauze if found to be still healthy, and is drained if diseased. Even in the absence of pus, where the descending infection expresses itself by spreading edema and infiltration, the exposure of the vascular sheath and the wide opening of the loose connective tissue spaces of the neck combined with prophylactic collar mediastinotomy, appears to be the only logical method. When used early, the typical external operation is a life saving procedure in abscesses descending into the neck and mediastinum.

Acute Bacillus Coli Infection of the Gastrointestinal Tract in the Newborn Child.—R. Chalmers, (*Lancet,* October 20, 1923) maintains that many of the gastrointestinal disorders of early infancy are the result of toxemia in the mother acting on the fetus in utero. Early jaundice, flatulence, vomiting and difficulties of providing a suitable diet are always more likely to be encountered in children of mothers who were afflicted with toxemia during their pregnancy than in other infants. It cannot always be determined with certainty whether the infection is of antenatal, natal, or postnatal in origin, as all three types have been found. A streptococcus infection is often combined with a Bacillus coli infection in the mother, in which case the streptococcus infection is primary and the Bacillus coli infection is secondary. Inasmuch as both of these organisms are found in the uterine discharge, it is possible for the child to become infected with mucus during its passage through the maternal passages.

Stridor in Infancy and Early Childhood.—Karl Hochsinger (*Wiener klinische Wochenschrift,* October 11, 1923) distinguishes five types of stridor occurring in early infancy and childhood: 1. Congenital inspiratory stridor, which is not due to catarrhal conditions in the respiratory tract, but to enlargement of the thymus, and is consequently followed by remarkable success with roentgenotherapy. 2. Expiratory whooping occurs in tuberculosis of the pulmonary lymph glands during the first year of life. It is important that this form should be recognized while it may still occur in an isolated area. 3. Stridor in bronchotetany affects inspiration and expiration to the same extent and is difficult to differentiate from the stridor occurring in inflammatory diseases of the lung (gradual onset, galvanic hyperexcitability and a good reaction to an antispasmodic dietary). 4. Pharyngeal stridor occurs in retropharyngeal lymphadenitis. 5. Stridor also occurs in pseudocroup.

Fate of the Premature Infant.—As a result of his investigations, Paul Brandt (*Monatsschrift für Kinderheilkunde,* December, 1923) draws the following conclusions: The fate of the prematurely born infant is not very rosy. About ten per cent of these infants weigh less than 2500 grams and are less than 46 cm. long at birth. About forty-two per cent of these infants die before the first year. The majority of them are sickly. Their only salvation lies in careful nursing, the application of heat, and dietotherapy. The most careful nursing is a prime requisite. The author has at his disposal a special room for premature infants, which is kept at a room temperature of 24°C. All draughts from opening of the door are avoided by the use of screens and the room is entered only by the physician and the nurse. The infants are put in baskets which are loosely lined with linen. Very small infants are wrapped in cotton. A veil of gauze is laid over the baskets and special heat is supplied by hot water bottles. Every form of cooling is most carefully avoided and bathing is omitted in the first few weeks. During the first few days and weeks the food consists of breast milk, which is later supplanted by mixed feeding with breast milk—albumin milk—and buttermilk and after a few months by cow milk mixtures. Phosphorus with codliver oil is given in every case from the beginning of about the second month as a prophylactic. These infants require the most careful watching for the first year.

The Neonatal Period from a New Point of View.—As a result of some colloid chemical investigations on serum, Josef Duzár (*Monatsschrift für Kinderheilkunde,* December, 1923) maintains that the neonatal period must be divided into two periods, of which the first extends from the first to the tenth to the fourteenth day of life and the second period up to the end of the second month of life. The first period is characterized by permeability of the gut, hydrolability, a tendency toward edemas and to infectious diseases and the lack of antibody formation. It also shows certain peculiarities, as evidenced by immaturity of heat regulation, a tendency toward erythemata of the skin and mucous membranes, initial loss of weight, transitory fever, uric acid infarcts and icterus neonatorum as a sign of hypofunction of the liver.

Puncture of the Cisterna Magna in Children.—James G. Kramer (*Ohio State Medical Journal,* May, 1924) avers that puncture of the cisterna magna is a justifiable procedure. In the treatment of cerebrospinal meningitis and its complications it is the method of choice in giving serum. In conjunction with lumbar puncture it should be used for spinal lavage and diagnosis. For the righthanded operator the child is placed in the left lateral position while an assistant flexes the head on the body and the thighs on the abdomen. The palm of the left hand is placed over the upper occiput and parietal region with fingers outstretched to hold the head firmly on the table. The thumb is placed so as to mark the upper edge of the recess between the external occipital protuberance and the spine of the axis. With the right hand the ordinary lumbar puncture needle is inserted in the midline just below the occipital protuberance, as guided by the left thumb, and it is directed in a line drawn over the external auditory canal and the glabella. It goes through the soft tissues easily until it arrives at the occipitoallantal ligament, which extends from the posterior border of the foramen magnum to the atlas. Here resistance is encountered which is overcome by firm steady pressure, which pressure is released when the sensation of "give" or sudden loss of resistance is felt. The distance from dura to medulla is one and one-half cm. in the adult, but when the upward direction of the needle is considered, 2.5 to 3.0 cm. may be traversed before damage is done.

Differential Diagnosis of Umbilical Colic.—Felix Metis (*Monatsschrift für Kinderheilkunde,* December, 1923) examined the leukocyte picture of twenty children, mostly girls, who were afflicted with repeated attacks of abdominal pain, located principally around the umbilicus. The investigations covered not only the content of neutrophiles but also the displacement to the left; they also included the acidity of the gastric juice. There was no shifting to the left. All the patients showed evidences of a neurotic temperament. The pains are attributed to intestinal spasms. The most important element in the treatment is that of the neuropathy.

Infant Feeding Simplified for the General Practitioner. Maurice Blatt (*Illinois Medical Journal,* February, 1924) asserts that normal infants gain well and have the minimum of gastrointestinal disturbance on mother's milk or mother's milk plus complemental feeding. Artificially fed infants thrive on formulas based upon an initial feeding of one and one half ounces of milk and one tenth of an ounce of carbohydrate to the pound of body weight, diluted with water to make a total daily feeding of the number of ounces represented by the age in months plus two, multiplied by five. Blatt also advises phosphorized codliver oil from the third month, and he also starts both cereals and green vegetables at this age. The nursing or feeding interval recommended is the four hour one from birth, six feedings daily. An infant will take at least two ounces more at a feeding than its age in months; boiling milk for two minutes makes the casein curd smaller.

Czerny Butter Flour Mixture.—L. J. Wisch (*Journal of the Indiana State Medical Association,* April, 1924) records the following contraindications to the butter flour mixture: 1. It should not be used in cases where the malnutrition is due to some specific wasting disease as syphilis or tuberculosis. 2. It is contraindicated in acute nutritional disturbances such as disturbed metabolic balance or acute dyspepsia. 3. It is usually disastrous in chronic indigestion with fat intolerance. It finds its useful sphere in premature infants of enfeebled nutrition, marasmus, and chronic dyspepsia.

Value of the Low Fluid Content of the Butter Flour Mixture.—Harry M. Greenwald (*Archives of Pediatrics,* December, 1923) states that butter flour mixture is an artificial infant food simply and easily prepared. With its use the artificially fed infant is satisfied by a fluid bulk not exceeding that normally ingested by the breast fed infant. It permits the employment of fat, an important factor in the child's economy, without the manifestations of such disturbances as are frequently observed in the use of the ordinary fat enriched mixtures. In butter flour mixture we have a food that, in quantity and in the correlation of fat, proteid and carbohydrate to one another, more nearly simulates breast milk than any other mixture heretofore employed.

Tuberculosis in Childhood.—Murray Bass (*Journal of the Medical Society of the State of New Jersey,* April, 1924) states that hilus infection with tuberculosis is the usual type found in childhood and that the involvement of the tracheobronchial glands is secondary to a primary focus of infection in the lung. This primary focus is sometimes so minute as to almost baffle discovery. Infiltration of the apex of the lung and cavity formation, so often seen in adults, are rare in children especially under ten years of age. The aerogenous route of infection is by far the commonest but the alimentary tract and the tonsils may be portals of infection. In America the type of infection is the human in ninety per cent. of all cases, thus leaving only ten per cent. due to bovine bacilli.

Scoliosis: Its Prevention and Treatment.—S. Kleinberg (*Archives of Pediatrics,* December, 1923) remarks that structural scoliosis is a fixed deformity of the spine and trunk which occurs very frequently among children. The surest procedure for the early recognition of scoliosis is the periodical examination of the naked back of every school child, and particularly of the children between the ages of five and ten years. In a small percentage of cases the scoliosis remains mild. But inasmuch as we have no criteria by which we can judge whether a given deformity will remain mild or grow worse, and since we know from experience that in many cases moderate and even severe grades of deformity develop, with consequent serious interference with the functions of the thoracic and abdominal organs, it is advisable that treatment should be instituted just as soon as the deformity is discovered. There is no known treatment by which we can cure structural scoliosis, but there are several systems of treatment by which sixty to seventy per cent. of the patients can be improved and often to a highly satisfactory degree.

The essential in all treatment is the correction of reduction of the curve by the voluntary or forced assumption of that attitude of the body which is the direct opposite of the attitude of the deformity. This may be obtained by corrective plaster jackets, plaster or celluloid corsets, spinal braces, or gymnastic exercises.

Clinical Aspect and Etiology of Perthes-Calvé-Legg's Disease (Osteochondritis Deformans Juvenilis).—H. Reich (*Schweizerische medizinische Wochenschrift,* December 13, 1923) states that this disease occurs much more frequently than has been believed heretofore. It affects particularly children between the ages of four and eleven years. Boys are affected much more often than girls. It may be both unilaterel and bilateral. The pathologicoanatomical investigations reveal the presence of a primary necrotic focus with subequent granulation tissue in the head of the femur. As a result of weight bearing the less resistant head becomes spread out in width. The etiology is still uncertain; it may be produced by various causes. The general constitution, particularly disturbances in the thyroid gland activity, play a more important part than has been admitted heretofore. The clinical picture is characteristic: it has an insidious onset with pains and limping, both of which are slight. Very early there is limitation in the movements of the diseased hip, almost always in abduction and rotation. All the other symptoms, which play an important part in the diagnosis of diseases of the hip-joint, are not pronounced and show no characteristic behavior. Marked pains and great favoring of the affected side on walking and muscular tension are almost never observed. The general condition is not affected. The x ray plate reveals typical changes, which cannot be mistaken for any other disease. It provides the most definite diagnosis and is a valuable aid in the observation of the course of the disease. In the differential diagnosis, tuberculous coxitis is the most important disease. The tuberculin test is valuable as a differential test. These two conditions also show absolutely different pictures in the röntgenogram. The differentiation from coxa vara is possible only with the röntgenogram. It is not difficult to eliminate congenital dislocation of the hip. The course of the disease is chronic, lasting for years, and during this time the upper end of the femur undergoes a complete change in form. In the final stage, abduction and rotation are permanently limited.

There are no subjective symptoms, with the exception of an occasional persistent slight limping. Conservative treatment is the best. With rare exceptions, the patients go about quite freely, but they should avoid marked exertion.

It is advisable for the patient to take massage, mud baths and passive motion so as achieve the widest possible excursions of abduction and rotation. In certain cases plaster casts give good results as they prevent excessive deformity of the head of the femur. In patients with deficient thyroids treatment with thyroid gland preparations may be tried.

NEUROLOGY

The Regulating and Reflex Process.—P. T. Herring (*British Medical Journal,* October 20, 1923), in commenting upon the importance of the synapse in the regulating and reflex process, states that drugs exert their influence on the nervous system on the synapses or the receptive substances between the endings of the efferent nurons and the organs which they supply. Fatigue is the result of the action of waste products on these structures. Certain toxins have a similar action. Various substances affect different synapses and spread from these in a definite manner. They may affect first the synapses in the highest level of the nervous system, as does chloroform, and gradually spread to the synapses at lower levels, affecting the pathways of the vital reflexes only at the end. It may also begin in the receptive substances and cause death from paralysis of the respiratory muscles, as in curare poisoning. In atropin poisoning or in overdosing with digitalis it may gradually ascend to the higher levels. Many of the signs of ill health may be due to toxins acting on different parts of the nervous system. This theory would explain the symptoms of botulism and their seriousness might be explained by the involvement of the synapses on the reflex arcs of the vital processes at an early stage. More common conditions might be explained by affections of less vital processes. Exhaustion, nausea, anorexia, temperature changes, cardiac, vasomotor, and visceral disturbances may be due to action of toxins on the synapses of the pathways concerned in the regulation of normal processes. Disturbances in the normal processes are recognizable by the subjective sensations and by the alterations in the reflexes.

Phenobarbital and Potassium Borotartrate in Epilepsy.—M. Regnard (*Bulletin général de thérapeutique,* December, 1923) states that he has obtained good results with both of these agents. In some cases, however, their combined use is preferable, for the purpose of avoiding the psychic disturbances sometimes witnessed following the use of phenobarbital (luminal) alone. In most patients, especially at the beginning of treatment, ingestion of phenobarbital causes marked constipation, which is effectually counteracted by the laxative properties of potassium borotartrate. The treatment is usually begun by prescribing two grams a day of the borotartrate and 0.1 gram of phenobarbital. If the seizures persist, the daily dose of the borotartrate is increased to three grams; on the other hand, if improvement is seen, the dose of phenobarbital is reduced to 0.05 or even 0.02 gram. a day. The treatment can then be kept up for months, or even years without exerting any pronounced untoward action.

Traumatic Neurasthenia.—E. Farquhar Buzzard (*Lancet,* December 15, 1923) believes that the signs and symptoms of traumatic neurasthenia correspond with those of anxiety neurosis, complicated by certain factors, and he considers it as an emotional condition, which is not dependent upon any physical disturbance induced by any trauma but upon a number of psychological factors. Even though the development of neurasthenia is favored by the knowledge that an injury has been sustained, nevertheless the neurasthenia is not directly due to the trauma. The author prefers the term "anxiety neurosis following trauma."

MEDICAL JOURNAL AND RECORD

Medicolegal Notes.

EVIDENCE OF PARALYSIS OF LARYNX ADMISSIBLE TO PROVE IMPAIRMENT OF VOICE.

In an action for injury sustained by contact with an electric wire, evidence of physicians that the left side of plaintiff's larynx was paralyzed, and that he suffered from paralysis of the muscles to which the vocal cords are attached, was held admissible though no allegations of such injuries were pleaded, where it was alleged that plaintiff's voice would be weakened and impaired, since a paralysis of the larynx or its muscles necessarily proves an injury to the voice.—Smissman v. Wells (Mo. App.), 225 S. W. 935.

ARMY SURGEON COMPETENT AS MEDICAL WITNESS

The Colorado Supreme Court holds, Patton v. People, 221 Pac. 1086, that the evidence of a medical witness was admissible in a murder case although he did not have a license to practice in the State where it was shown that he was a regularly licensed and practicing physician and surgeon, and also that he was a commissioned surgeon in the United States army, and as such was not prohibited from performing his lawful duties in the State.

PATIENT'S STATEMENTS OF PAST CONDITION NOT ADMISSIBLE.

In a personal injury case testimony given by the plaintiff's physician, detailing statements made by plaintiff to the physician while under his treatment, as to the state of his health before and after the injury, was held to be a violation of the rule against the admission of the statements of the patient with respect to his past condition and the history of the case. Adolf v. Brown (Mo. App.), 255 S. W. 947. But the admission of this evidence was held to be harmless error when the facts had been otherwise established by competent evidence and were not disputed.

PRIVILEGED COMMUNICATIONS—THEIR NATURE.

The Montana Supreme Court, Garrett v. City of Butte, 221 Pac. 537, recognizes the general rule that the incompetency of a physician to testify concerning information acquired while attending a person in a professional capacity extends to staff physicians of a hospital; but the information obtained in order to place such evidence under the ban as respects the physician or an attendant physician must be such as is necessary to prescribe for the patient. In an action for injuries sustained by falling on an icy sidewalk it was held that a statement of the plaintiff to the staff physician of the hospital where she was treated that she fell at a different place from that alleged by her in her complaint did not come within the rule of exclusion of privileged communications.

RECOVERY FROM PHYSICIAN FOR MALPRACTICE AND FOR HIS NEGLIGENCE CAUSING THE ORIGINAL INJURY.

The Missouri Supreme Court holds, Parkell v. Fitzporter, 256 S. W. 239, that where a physician negligently ran down and injured a person, and by subsequent malpractice in the treatment of the injured person's leg aggravated the injury, the fact that the latter recovered damages in an action for damages for the negligent operation of the automobile did not preclude recovery in another action for damages caused by the malpractice. The malpractice alleged consisted in sewing into a wound in plaintiff's leg a metal garter buckle which had been driven into the wound by the collision, inducing infection and gangrene, resulting in permanent disability.

ORDINANCE FORBIDDING ADULTERATION OF MILK HELD VALID.

The Arizona Supreme Court, Gardenhire v. State, 221 Pac. 228, holds that a statute authorizing a town to prescribe regulations "necessary and expedient for the prevention or suppression of disease," taken and construed together with the law creating boards of health, gave the legislative body of the town of Yuma, impliedly, if not directly, power to license and regulate the sale of milk and its products within its limits, and to forbid its adulteration, and to punish those violating ordinances enacted for that purpose.

NEGLIGENCE OF PHYSICIAN HELD NOT FOR JURY WITHOUT EXPERT TESTIMONY

The Nebraska Supreme Court holds, Tada v. Warta, 196 N. W. 901, that, "in an action against a physician for malpractice where the acts as negligence require in their performance the exercise of professional skill and knowledge, and are such with respect of which a layman can have no knowledge at all, the jury may not draw the inference of negligence without the aid of expert testimony as to the quality of such acts to guide them; in which case the doctrine of 'res ipsa loquitur' has no application."

LATENT ACCIDENTAL INJURY FOUND TO "OCCUR" ON BEING DISCOVERED BY X RAYS

The Nebraska Supreme Court, Selders v. Cornhusker Oil Co., 196 N. W. 316, holds that a latent accidental injury to a workman, seeming at first to be trifling but subsequently resulting in disability, may be found to "occur" when discovered by means of x rays, within the meaning of the Nebraska Workmen's Compensation Law, providing that no proceeding for compensation shall be maintained unless the claim therefor is made within six months from the occurrence of the injury.

GENERAL HOSPITAL HELD NOT OBJECTIONABLE IN RESIDENTIAL SECTION

The Nebraska Supreme Court hold, Thompson v. Evangelical Hospital Association, 196 N. M. 117, that the fact that a hospital in itself is objectionable to those residing in close proximity to the site of a proposed hospital, or that the value of property in the neighborhood may be adversely affected, do not ordinarily constitute sufficient grounds to warrant a decree enjoining its erection. The court said: "In modern life a hospital is a public necessity, and to be of service to the public it must be so situated as to have available for its use electric current, gas mains and sewers. And, as many of the patrons will be without private conveyances and obliged to depend upon the street cars for service to and from the hospital, it is almost imperative that it be located where these conveniences are accessible."
